quills, with a thick cork-like epidermis, very bitter, and yielding an aromatic odor when burnt. The former is the product of *Croton Pseudochina*, Schlechtendal, *C. niveus*, Jacquin; the latter is of unknown origin, but conjecturally referred to *C. suberosus*. J. E. Howard states that the quilled copalchi bark contains a bitter alkaloid, soluble in ether, and precipitable as a white hydroxide from its acid solution. (*P. J.*, xiv. 319.) Copalchi bark is an aromatic tonic, employed in Mexico in intermittents, and capable of useful application in all cases requiring a mild aromatic bitter. Stark has employed it advantageously in feeble states of digestion with irritable bowels, and found it in one or two cases, to exhibit antiperiodic properties. It may be given in infusion, made with half an ounce of the bark to a pint of water, in the dose of one or two fluidounces three times a day. (*Ed. Med. and Surg. Journ.*, April, 1849, p. 410; see also *P. J.*, 1886, p. 917.)

²The plant referred to in very early editions of this work as having been seen by Wright in Jamaica, and called by him *C. Eluteria*, is, according to Bennett, a distinct species, *C. Sloanei*, which was confounded by Linnaeus with the genuine cascarilla plant, under the name of *Clusia Eluteria*. The genuine plant was first described by him in his *Hortus Cliffortianus* (pp. 486-7), from a specimen in Clifford's herbarium in the British Museum, and afterwards apparently confused with a Jamaica specimen sent to him by Patrick Brown, from the latter of which the description of his *Clusia Eluteria* was drawn up, which is quite inapplicable to the original plant. It is the *C. Sloanei* also that was described by Schwartz in his *Flora Indis Occidentalis* (p. 1183), under the name of *Croton Eluteria*, and probably the same that was figured by Carson in his *Illustr. of Med. Bot.*, ii. 34, pl. 78. (See *P. J.*, 1859, pp. 132-3.)

ing with a short fracture. When burned it emits a pleasant odor, closely resembling that of musk, but weaker and more agreeable. This property serves to distinguish it from other barks. It was analyzed by Trommsdorff, and more recently by Duval of Lisieux, in France. The constituents found by the latter were albumen, a peculiar kind of tannin, a bitter crystallizable principle called *cascarillin*, a red coloring matter, fatty matter of a nauseous odor, wax, gum, volatile oil, resin, starch, peptic acid, potassium chloride, a salt of calcium, and lignin. The oil, according to Trommsdorff, constitutes 1.6 per cent., is of a greenish-yellow color, has a penetrating odor analogous to that of the bark, and is of the sp. gr. 0.938. G. Feudler (*A. Pharm.*, 1900, p. 671) finds the oil to contain about 2 per cent. of free acid, which consists of a liquid acid, $C_{11}H_{20}O_2$, to which the name of *cascarillic acid* was given, and a solid portion made up of a mixture of palmitic and stearic acids. The oil contains 0.3 per cent. of *eugenol*, a terpene differing from pinene, *cymene*, possibly some *l-limonene*, two sesquiterpenes and an alcohol, $C_{15}H_{32}OH$. To obtain cascarillin, Duval treated the powdered bark with water, added lead acetate to the solution, separated the lead by hydrogen sulphide, filtered, evaporated with the addition of animal charcoal, filtered again, evaporated at a low temperature to a syrupy consistence, and, having allowed the semi-liquid substance thus obtained to harden by cooling, purified it by twice successively treating it, first with a little cool alcohol, to separate the coloring and fatty matters, and afterwards with boiling alcohol and animal charcoal. The last alcoholic solution was allowed to evaporate spontaneously. Thus obtained, cascarillin is white, crystalline, inodorous, bitter, very slightly soluble in water, soluble in alcohol and ether. (*J. P. C.*, 3e sér., vii. 96.) It melts at 205° C. (401° F.), is not volatile nor a glucoside. Its composition answers to the formula $C_{12}H_{18}O_4$. P. E. Alessandri regards *cascarilline* as an alkaloid, and obtains it economically by mixing powdered cascarilla with sufficient 3 per cent. aqueous solution of oxalic acid to cover it, shaking the mixture, and heating it to 140° F., then allowing it to cool, expressing the mixture and saturating the filtered liquor with ammonia, then evaporating at a low temperature to two-thirds of its bulk, allowing it to cool, and separating any deposit. The clear liquid is then shaken with ether; this takes up the cascarilline, which may be obtained through evaporation of the ethereal liquid. (*L'Orosi*, v. 1; *P. J.*, 1882, 993.) R. A. Cripps was unable to obtain the alkaloid by Alessandri's method, and suggests that the bitterness of the so-called cascarilline might be due to adherent resin. (*P. J.*, 1886, 1103.) Either alcohol or water will partially extract the active matters of cascarilla; but diluted alcohol is the proper menstruum. Naylor and Littlefield have reviewed the processes of Duval and

Alessandri for preparing cascarilline, and find that Duval's method gives the purer product. They find its melting point to be 203.5° C., and give it the formula $C_{12}H_{24}O_8$. (*Y. B. P.*, 1896, 301.) W. A. H. Naylor subsequently found *betaine* in cascarilla. (*P. J.*, 1898, 279.)

Uses.—This bark is aromatic and tonic. It was known in Germany so early as the year 1690, and was much used as a substitute for Peruvian bark by those who were prejudiced against that febrifuge in the treatment of *remittent* and *intermittent fevers*. It has, however, lost its reputation, and is now employed only where a pleasant and gently stimulant tonic is desirable, as in *atonic dyspepsia*, and other cases of debility of the stomach or bowels, especially in combination with the more powerful bitters. It may be given in powder or in infusion. Procter published a formula for a fluidextract which contains the virtues of a troyounce of the bark in a fluidounce. (*A. J. P.*, 1863, p. 113.) In consequence of its pleasant odor when burned, some smokers mix it in a small quantity with their tobacco; but it is said to occasion vertigo and intoxication.

Dose, twenty to thirty grains (1.3 to 2.0 Gm.).

CASSIA FISTULA. U. S. (Br.)

CASSIA FISTULA [Purging Cassia]

(cās'si-ā fist'ù-lā)

"The dried fruit of *Cassia Fistula* Linné (*Fam. Leguminosæ*)." U. S. "The pulp obtained from the pods of *Cassia Fistula*, Linn." Br.

Cassia Pulpa, Br.; Cassia Pulp, Pudding-stick (or pipe); Fructus Cassia Fistula; Casse Officinale, Fr. Cod.; Casse en bâtons, Pulpe de Casse, Casse Mondée, Casse, Fr.; Röhrenkassie, Purgirkassie, Fistelkassie, G.; Cassia, It.; Cana fistula, Sp.

The tree which yields the purging cassia is ranked by some botanists as a distinct genus, separated from the Cassia, and denominated *Cathartocarpus*. (See *Limley's Flor. Med.*, 262.)

Cassia Fistula, Willd., *Sp. Plant.* ii. 518; Carson, *Illust. of Med. Bot.* i. 24, pl. 26; B. & T. 87.—*Cathartocarpus Fistula*, Persoon, *Synops.* i. 459.—This is a large tree, rising to the height of forty or fifty feet, with a trunk of hard, heavy wood, dividing towards the top into numerous spreading branches, and covered with a smooth ash-colored bark. The leaves are commonly composed of five or six pairs of opposite leaflets, which are ovate, pointed, undulated, smooth, of a pale green color, from three to five inches long, and supported upon short petioles. The flowers are large, of a golden yellow color, and arranged in long, pendent, axillary racemes. The fruit consists of long, cylindrical, woody, dark-brown, pendulous pods, which when agitated by the wind strike against each other and produce a

sound that may be heard at a distance. This species of Cassia is a native of Upper Egypt and India, whence it is generally supposed to have been transplanted to other parts of the world. It is at present very extensively diffused through the tropical regions of the old and new continents, being found in Insular and Continental India, Cochín-China, Egypt, Nubia, the West Indies, and the warmer parts of the continent of America. Under the name of *Golden Shower* it is known as an ornamental shade tree in all tropical countries. The fruit is the official part of the plant. It is imported from the East and West Indies, chiefly the latter, and from South America.

Properties.—Cassia pods are a foot or more in length, straight, or but slightly curved, cylindrical, less than an inch in diameter, with a woody shell, externally of a dark-brown color, and marked with three longitudinal shining bands, extending from one end to the other, two of which are in close proximity, appearing to constitute a single band, and the third is on the opposite side of the pod. These bands mark the place of junction of the valves of the legume, and are represented as sometimes excavated in the form of furrows. There are also circular depressions at unequal distances. The official description is as follows. "Cylindrical, 25 to 50 Cm. long, about 20 Mm. in diameter, chestnut-brown in color, on one side a longitudinal groove and on the other a smooth line or slight ridge, indicating the two sutures; indehiscent, the cavity divided transversely into numerous compartments, each containing a reddish-brown, glossy, flattish-ovoid seed embedded in a blackish-brown pulp; with an odor resembling that of prunes, and a mawkish sweet taste." *U. S.* The pods brought from the East Indies are smaller, smoother, have a blacker pulp, and are more esteemed than those from the West Indies. We have seen pods in the American market sold as cassia pods, which were an inch and a half in diameter, flattened on the sides, exceedingly rough on the outer surface, and marked by three longitudinal very elevated ridges, corresponding to the bands or furrows of the common cassia. The pulp was rather nauseous, but in other respects seemed to have the properties of the official purging cassia. They corresponded exactly with a specimen of the fruit of *Cassia brasiliana*, Lam., brought from the West Indies, and were probably derived from that plant.

The heaviest pods, and those which do not make a rattling noise when shaken, are to be preferred, as they contain a larger portion of the pulp, which is the part employed. This should be black and shining and have a sweet taste. It is apt to become sour if long exposed to the air, or mouldy if kept in a damp place. The pulp is extracted from the pods by first bruising them, then boiling them in water, and afterwards evaporating the decoction; or, when the pods are fresh, by opening them at the sutures and removing the pulp with a spatula.

Cassia pulp has a slight odor, and a sweet mucilaginous taste. According to Henry it contains sugar, gum, coloring matter, and a tannin-like substance; while Haensel obtained from it by steam distillation a dark yellow volatile oil, also butyric acid. (*Ph. Ob.*, 41.)

Uses.—Cassia pulp is laxative, and may be advantageously given in small doses in cases of *habitual costiveness*. In quantities sufficient to purge, it occasions nausea, flatulence, and griping. In this country it is rarely prescribed, except as an ingredient in the official confection of senna, which is a pleasant and useful laxative preparation.

Dose, of the pulp as a laxative, one or two drachms (3.9 or 7.7 Gm.), as a purge one or two ounces (31 or 62 Gm.).

CATAPLASMA KAOLINI. *U. S.*

CATAPLASM OF KAOLIN

(căt-ă-plăs'mă kă-ŏ-lī'nī)

Cataplasme de terre à porcelaine, *Fr.*; Porzellanthonumschlag, *G.*

* "Kaolin, in very fine powder, five hundred and seventy-seven grammes [or 20 ounces av., 154 grains]; Boric Acid, in very fine powder, forty-five gramme [or 1 ounce av., 257 grains]; Thymol, one-half gramme [or 8 grains]; Methyl Salicylate, two grammes [or 31 grains]; Oil of Peppermint, one-half gramme [or 8 grains]; Glycerin, three hundred and seventy-five grammes [or 13 ounces av., 99 grains]; to make about one thousand grammes [or 35 ounces av., 120 grains].

Heat the Kaolin in a suitable vessel at 100° C. (212° F.), with occasional stirring for one hour; mix it intimately with the Boric Acid, and then incorporate the mixture thoroughly with the Glycerin; finally add the Thymol, which has been dissolved in the Methyl Salicylate and the Oil of Peppermint, and make a homogeneous mass. It should be kept in an air-tight container." *U. S.* This cataplasm was introduced into the *U. S. Pharmacopœia* (8th Rev.), to supply the demand for an antiseptic poultice; the kaolin should be carefully sifted before using and the usefulness of the preparation will largely depend upon the thoroughness with which the ingredients are mixed. Kaolin varies somewhat in its absorptive properties and the quantity of glycerin, directed in the official formula, will be found slightly insufficient for some kinds of kaolin found in commerce. Cataplasm of kaolin is a grayish paste of soft consistence having the aromatic odor of the antiseptic used in the process. It is very important to keep it closely covered at all times, as the glycerin which is present has the tendency to absorb moisture from the atmosphere and impair the usefulness of the cataplasm.

Uses.—Cataplasm of kaolin may be applied warm in local inflammations in which a poultice is useful. It has been highly lauded in *pneumonia*, but it is doubtful if it has any advantage, aside from ease of application, over the flaxseed poultice.

YELLOW WAX

(cē'ra flā'vā)

"A solid substance prepared from the honeycomb of the bee, *Apis mellifera* Linné." U. S. "Prepared from the honeycomb of the Hive Bee, *Apis mellifica*, Linné." Br.

Cera Citrina; Beeswax; Cire Jaune, Cire d'Abelles, *Fr.*; Cera Flava, *P. G.*; Gelbes Wachs, *G.*; Cera gialla, Cera vergine, *It.*; Cera amarilla, *Sp.*

The name *Apis mellifera* was given to the honey-bee by Linnæus in 1758, *Systema Naturæ*, 10th edition; subsequently (*Ibid.*, 12th edition, 1767), Linnæus changed the name to *mellifica*, but according to the established rules of scientific nomenclature the first name must hold, and the revisers of the United States Pharmacopœia were therefore correct in adopting it. It was at one time doubtful whether the wax which constitutes the walls of the honeycomb is elaborated or merely gathered by the insect. Huber, however, by feeding bees exclusively on honey and water, determined that under these circumstances wax is produced in the form of scales under the rings of the abdomen. But wax also exists in plants, bearing in this, as in other respects, a close analogy to the fixed oils.¹

¹ Besides the official species other bees are used as honey makers. The extremely vicious, blackish-brown *Apis fasciata* was kept by the ancient Egyptians on floating apiaries, which as the season progressed slowly drifted down the Nile, following the successive opening of the flowers. In Senegal, *Apis adansonii*, and in Southern Africa *Apis caffra* and *Apis scutellata* produce honey; while the *Apis unicolor* of Madagascar has been domesticated in that island and introduced into other parts of the world. In India honey is made in large quantities by *Apis dorsata* (the largest of known bees) (*Apis indica*, *Apis florea*). *India Wax* differs from official wax chiefly in its lower acid value. A wax is also produced in India by the so-called *Kota bees*, belonging to the genus *Melipona*; they are minute stingless insects, which furnish a sticky, dark-colored wax, resembling in physical and chemical characteristics the propolis of the honey bee rather than the true wax.

1. CERA FLAVA, or *Yellow Wax*.—This is obtained by slicing the comb taken from the hive, draining and afterwards expressing the honey, and melting the residue in boiling water, which is kept hot for some time in order to allow the impurities to separate and either subside or be dissolved by the water. When the liquid cools the wax concretes, and, having been removed and again melted in boiling water, is strained and poured into pans or other suitable vessels. The labor saving device is sometimes adopted of stretching a strainer of cheese cloth upon a hoop and wedging the latter down into the hot mixture below the level of the water; as this cools, the melted wax slowly rises through the cloth, and thus a perfectly clean cake of wax is formed on top on cooling. It is usually brought to market in round flat cakes of considerable thickness. The druggists of Philadelphia are supplied chiefly from the Western States and North Carolina, especially the latter, and from Cuba and California.

Properties.—Yellow wax is "a yellowish to brownish-yellow solid, having an agreeable, honey-like odor, and a faint balsamic taste. Specific gravity: 0.951 to 0.960 at 25° C. (77° F.).² Melting point: 62° to 64° C.

China wax, called *pe-la* by the Chinese, resembles spermaceti in whiteness and crystalline appearance, but is distinguished by greater hardness and friability and a somewhat fibrous fracture. It melts at about 83° C. (181° F.), is very slightly soluble in alcohol or ether, is insoluble in cold oil of turpentine and rectified petroleum, but is dissolved with the aid of heat, and is very soluble in benzene. These solubilities distinguish it from spermaceti. (*P. J.*, xiv. 9.) It was formerly supposed to be of vegetable origin, but has been ascertained to be the product of an insect *Coccus ceriferus* deposited on the twigs of the Chinese Ash, *Frazinus Chinensis* (Roxburgh), and, investing them closely, becomes embedded in a waxy material, which is scraped off with the insects, and constitutes the crude wax. It is purified by melting and straining. (*Hanbury P. J.*, xii. 476.) T. T. Cooper, in his "Travels of a Pioneer" in China, gives some interesting statements as to the production of this wax, which are the result of his own personal observations. It is chiefly the province of S'zechuan which is the seat of this industry, the cultivation of the China wax being a source of great wealth to this province, second only in importance to the silk culture. The "wax trees" are all cut down at the height of 8 feet, leaving no branches, the trunks being about as thick as a man's thigh, and sending forth shoots in the spring. The insects are cultivated in a different province, that of Yunnan, whence vast quantities of the eggs are sent annually to S'zechuan, where they are received in little balls of the size of a pea. These are suspended, enclosed in young leaves, to the shoots of the tree in March. In about two months the larvæ appear, and, feeding on the leaves, soon attain the size of small butterflies, and spread themselves in immense numbers over the branches, which are whitened by them so as to seem covered with feathery snow. The grub, as it advances to the chrysalis form, buries itself in a white secretion by which all the branches are coated an inch in thickness. These are then cut off near the stem and divided into small pieces, which are tied in bundles and put into large caldrons, where they are boiled in water till all the wax melts and rises to the surface. It is then skimmed off and run into moulds, where it hardens. In this form it is sold over the Empire, where it is used for candles and as medicine. (*P. J.*, 1872; also vol. xv., 1885.)

² Dieterich has modified Hager's method of taking the specific gravity of wax, as follows: A piece of wax is heated on the edge of a colorless flame, so that wax is melted wax may fall into alcohol placed in a saucer. Having thus obtained about a dozen wax-

(143.6° to 147.2° F.). It is somewhat brittle when cold, and when broken presents a dull, granular, not crystalline fracture. By the heat of the hand it becomes plastic. Yellow Wax is insoluble in water, sparingly soluble in cold alcohol; boiling alcohol dissolves the cerotic acid and a portion of the myricin. It is completely soluble in ether, chloroform, and in fixed and volatile oils; partially soluble in cold benzene or carbon disulphide, and completely soluble in these liquids at a temperature of 25° to 30° C. (77° to 86° F.). If 1 Gm. of Yellow Wax be boiled for half an hour with 35 Cc. of an aqueous solution of sodium hydroxide (1 in 7), the volume being preserved by the occasional addition of water, the Wax should separate on cooling without rendering the liquid opaque, and no precipitate should be produced in the liquid, after filtration through glass-wool or asbestos, on the addition of hydrochloric acid (absence of *fats* or *fatty acids*, *Japan wax*, or *rosin*). Hydrochloric acid should produce no precipitate in water which has been boiled with a portion of the Wax (absence of *soap*). If 5 Gm. of Yellow Wax be heated in a flask to 160° C. (320° F.), for fifteen minutes, with 25 Cc. of sulphuric acid, and the mixture then poured into a large excess of water, no notable amount of solid substance which cannot be decomposed by sulphuric acid on further treatment, should separate (absence of *paraffin* or *ceresin*). Yellow Wax saponified by alcoholic potassium hydroxide T.S. should show a saponification value of from 90 to 96 (see PART III, Test No. 99)." *U. S.* The British Pharm. states that yellow wax should be "firm, breaking with a granular fracture, yellowish, having an agreeable honey-like odor. Not unctuous to the touch. It should be readily and entirely soluble in hot oil of turpentine. It should not yield more than 3 per cent. to cold alcohol (90 per cent.), nor more than 50 per cent. to cold ether, and nothing to water or to boiling solution of sodium hydroxide, the two latter liquids after filtration neither being turbid nor yielding a precipitate on the addition of hydrochloric acid (absence of fatty acids, resin, and Japan wax). Specific gravity 0.960 to 0.970.

pearls, they are allowed to dry thoroughly by letting them remain on blotting paper for 24 hours. Eight portions of diluted alcohol are prepared, of the following specific gravities respectively: 0.960, 0.961, 0.962, 0.963, 0.964, 0.965, 0.966, 0.967, and the pearl is dropped into these liquids in turn. The specific gravity of the wax is of course the same as the specific gravity of that liquid in which the pearl remains floating indifferently in any part of the vessel. (See Remington's *Practice of Pharmacy*, page 78, *Loz's beads*.) Dieterich examined hundreds of specimens annually, and found the wax to vary in sp. gr. from 0.963 to 0.966. He also determined the specific gravities of the following substances some of which are used to adulterate wax: white wax, 0.973; cera japonica, Japan wax, 0.975; ceresin, half white, 0.920; ozokerite, crude, 0.952; rosin, common, 1.108; cacao butter, 0.980 to 0.981; pure rosin, 1.045; beef suet, 0.952 to 0.953; yellow wax, 0.963 to 0.964; ceresin, white, 0.918; ceresin, yellow, 0.922; spermaceti, 0.960; French rosin, 1.104 to 1.105; paraffin, med. hard, 0.913 to 0.914; stearin, A No. 1, 0.971 to 0.972; mutton suet, 0.961. (*A. Pharm.*, 1882, p. 55.)

Melts at 144.5° to 147° F. (62.5° to 63.9° C.) when tested in the following manner. Liquefy a small piece, and draw a little of the liquid Beeswax up into a capillary tube of not more than one millimetre in internal diameter; after it has been allowed to cool for three hours, fix a piece of the filled capillary tube to the bulb of a thermometer by a thread; immerse the bulb and tube in a beaker of water, and heat the latter gradually on a water-bath; at the moment the opaque rod of Beeswax becomes transparent, note the temperature. The solidifying point is two to three degrees lower than the melting point. 5 grammes of the Beeswax, melted in and mixed with boiling alcohol (90 per cent.), should require for neutralization not less than 1.6 cubic centimetres of normal alcoholic volumetric solution of potassium hydroxide, using phenol-phthalein as an indicator. Upon the further addition of 20 cubic centimetres of the volumetric solution, and well boiling for one hour under a reflux condenser, not less than 6.2 nor more than 6.8 cubic centimetres should be found to have combined with the Beeswax, as shown by the titration of the uncombined alkali with volumetric solution of sulphuric acid. If 5 grammes of Beeswax are heated for fifteen minutes with 25 grammes of sulphuric acid to 320° F. (160° C.) and the mixture diluted with water, no solid wax-like body should separate (absence of paraffin). Beeswax should not yield any characteristic reaction with the tests for starch." *Br.*

Various adulterations have been practised, most of which may be readily detected. Meal, earth, and other insoluble substances are at the same time discovered and separated by melting and straining the wax. When the fracture is smooth and shining instead of being granular, the presence of rosin may be suspected. This is dissolved by cold alcohol, while the wax is left untouched. Yellow wax is frequently adulterated with a mixture of paraffin and rosin; such wax is usually translucent on the edges. For other adulterating substances used, and the modes of detecting them, see the remarks which follow on white wax.

Yellow wax is used chiefly as an ingredient of plasters and cerates.

2. CERA ALBA, *Bleached Yellow Wax*, or *White Wax*.—The color of yellow wax is discharged by exposing it, with an extended surface, to the combined influence of air, light and moisture. The process of bleaching is carried on to a considerable extent in this country. The wax, previously melted, is made to fall in streams upon a revolving cylinder, kept constantly wet, upon which it concretes, forming thin ribbon-like layers. These, having been removed, are spread upon linen cloths stretched on frames and exposed to the air and light, care being taken to water and occasionally turn them. In a few days they are partially bleached; but, to deprive the wax completely of color, it is necessary to repeat the whole

process once, if not oftener. When sufficiently white, it is melted and cast into small circular cakes.¹ Yellow wax may also be decolorized by treatment with animal charcoal or with potassium permanganate, potassium dichromate and sulphuric acid, and hydrogen peroxide. White wax sometimes contains one or more free fatty acids, consequently probably upon the employment of alkalis in bleaching it, which render it an unfit ingredient in the unctuous preparations of certain salts. It may be deprived of these acids by means of alcohol.

Perfectly pure wax is white, shining, diaphanous in thin layers, inodorous, insipid, harder and less unctuous to the touch than the yellow, soft and ductile at 35° C. (95° F.) and fusible at 65° C. (149° F.), retaining its fluidity at a lower temperature. The U. S. Pharmacopœia describes it as "a yellowish-white solid, somewhat translucent in thin layers, having a faint, characteristic odor, and nearly tasteless. Specific gravity: 0.950 to 0.960 at 25° C. (77° F.). Melting point: 64° to 65° C. (147.2° to 149° F.). In other respects White Wax has the characteristics of, and should respond to the reactions and tests given under, *Cera Flava*." U. S.

By a great heat it is partly volatilized, partly decomposed; and, when flame is applied to its vapor, it takes fire and burns with a clear bright light. It is insoluble in water, and in cold alcohol or ether, but is slightly soluble in boiling alcohol and ether, which deposit it in a great measure upon cooling. The volatile and fixed oils dissolve it with facility, rosin readily unites with it by fusion, and soaps are formed by the action of sodium and potassium hydroxides. It is not affected by the acids at ordinary temperatures, but is converted into a black mass when boiled with concentrated sulphuric acid. Bleached wax contains, according to Lewy's analysis, 80.2 per cent. of carbon, 13.4 of hydrogen, and 6.4 of oxygen. It is a mixture of three different substances, which may be separated from one another by alcohol,—viz.: 1, *myricin*, insoluble in boiling alcohol, and consisting chiefly of myricyl palmitate ($C_{15}H_{31}O.OOC_{15}H_{31}$),—that is, a compound of *palmitic acid*, $C_{15}H_{31}O.OH$, and *myricyl alcohol*, $C_{30}H_{61}OH$; 2, *cerotic acid*, $C_{27}H_{54}O_2$ (formerly called *cerin* when obtained only in an impure state), which is dissolved by boiling alcohol, but crystallizes out on cooling;

3, *cerolein*, which remains dissolved in the cold alcoholic liquid. This latter is probably a mixture of fatty acids, as indicated by its acid reaction. Schwalb (*Ann. Chem.*, 224, 225) found melissic acid and some unsaturated acids of the oleic series; also higher solid hydrocarbons of the saturated series, such as $C_{27}H_{54}$ and $C_{31}H_{64}$. Kebler states that the hydrocarbons in beeswax amount to from 12.72 to 13.78 per cent. (*A. J. P.*, 1893, 587.) T. Marie believes that cerotic acid, as ordinarily obtained, is a mixture of two distinct acids. He gives $C_{30}H_{60}O_2$ as the formula for melissic acid and $C_{25}H_{50}O_2$ for pure cerotic acid.

Wax has been variously adulterated. Heavy substances sink to the bottom of the vessel when the wax is melted. *Starch*, *meal*, and other insoluble substances remain behind when the wax is dissolved in oil of turpentine or petroleum benzin. *Water*, which is said to be sometimes fraudulently incorporated with it, by agitation when partially melted, is driven off by heat. *Fatty substances* render lime water turbid when agitated with it and allowed to stand. For the detection of stearin and stearic acid, Lebel dissolves the suspected wax in two parts of oil, beats the cerate thus formed with its weight of pure water, and then adds a few drops of solution of lead subacetate. If stearin be present, there will be an immediate decomposition, and the mixture will acquire an extraordinary solidity from the formation of lead stearate. (*J. P. C.*, 3e sér., xv.) Vogel proposes chloroform as a means of detecting the adulteration with fatty matters. That liquid dissolves only 25 per cent. of wax, but stearin and stearic acid completely. If, therefore, wax treated with 6 to 8 parts of chloroform loses more than one-quarter of its weight, it may be considered as impure. (*Ibid.*, xvii.) Overbeck detects stearic acid by the abundant effervescence produced from the escape of carbon dioxide when a small portion of the suspected wax is boiled in a solution composed of one part of sodium carbonate and fifty of distilled water. (*P. J.*, xi. 128.) The best test for fats, fatty acids or rosin is the pharmacopœial test of boiling with sodium hydroxide solution and testing the filtrate obtained after cooling. For the detection of rosin, cold alcohol is sufficient. It dissolves the rosin, and yields it on evaporation, attended with a very small portion of pure wax, which yields 2.4 per cent. to cold alcohol. (Ed. Davies, *A. J. P.*, 1870, p. 537.) F. Jean states that a few drops of sulphuric acid added to the melted wax adulterated with rosin, cause a red color, or, if only 1 per cent. be present, a green tint. (*A. J. P.*, 1881, p. 307.) White wax should not melt below 65° C. (149° F.); yellow not below 62.5° C. (144.5° F.). (*Br.*) *Japan wax* is said also to be largely employed for adulterating beeswax; so that sometimes but little of the product of the bee is to be found in the mixture. To detect *Japan wax*, Dullo boils together for a minute 10 Gm. of wax, 120

¹ The following process for purifying wax by steam has been patented by Cassrand, in France, and is said to have been employed advantageously. Wax melted by steam is passed along with the steam through a coiled tube or worm, is received into a jacketed kettle heated by steam, where it is washed with water, and is then raised by a pump into another pan, also heated by steam, where it is again washed with water; the whole operation is repeated three or four times, the wax being allowed to rest for about four or five minutes in the upper pan after each operation, and, after the last one, an hour or two for the subsidence of impurities. The wax is then granulated by means of cold water, allowed to dry for two or three days, and then exposed to light and air. The whole process is completed in a few days. (See *A. J. P.*, xxvi. 525.)

Gm. of water, and 1 Gm. of sodium hydroxide; if Japan wax be present, a soap will immediately form, which will slowly solidify on cooling. Beeswax does not saponify under these circumstances. (*Ibid.*, 4e sér., i. 448.) Ceresin, a principle obtained from ozokerite (see PART II), is also employed as an adulterant, and is manufactured largely for that purpose in Vienna. It is only native paraffin, and of course answers to the tests for that substance. There are other less precise methods of detecting adulterations. Thus, spermaceti and lard render wax softer and less cohesive, of a smoother and less granular fracture, and of a different odor when heated. The melting point and specific gravity are lowered by tallow, suet, lard, and especially by paraffin. *Legrip's cereometer* is based upon the altered specific gravity of wax when adulterated. Anyone may apply this principle by making such a mixture of alcohol and water that pure wax will neither sink nor rise in it, but remain wherever placed. (See page 308.) Adulterated wax would either float or sink in this liquid. The most valuable information, however, is obtained by the determination, according to Hübl's process, of the three chemical constants,—viz., acid value, 20; ester value, 75; and saponification value, 95. In yellow wax the iodine value, 7.9 to 8.9, is also of use; in white wax the bleaching process has altered the bodies which absorb the iodine. (See also *Chem. Ztg.*, 1893, 918; *Proc. A. Ph. A.*, 1894, 957; *D. C.*, 1898, 33; *Am. Drug.*, 1898, 97, and 1904, 103, 105.)

Uses.—Wax has little effect upon the system. Under the impression that it sheathed the inflamed mucous membrane of the bowels, it was formerly prescribed in *diarrhœa* and *dysentery*; and it is mentioned by Dioscorides as a remedy in the latter complaint; but at the present time, we suppose, no one would think of employing wax for such purposes. Its sole use in modern medicine is in the formation of ointments, cerates, plasters, suppositories, and surgical dressings, etc.; in which it acts mechanically, either giving stiffness or serving to protect from water. It is an ingredient in almost all the official cerates, which owe to it their general title.

3. VEGETABLE WAX.—Many vegetable products contain wax. It exists in the pollen of numerous plants, and forms the bloom or glaucous powder which covers certain fruits, and the coating of varnish with which leaves are sometimes supplied. In some plants it is so abundant as to be profitably extracted for use. Such is the *Ceroxylon andicolum*, Humb., a lofty palm growing in the South American Andes. Upon the trunk of this tree, in the rings left by the fall of the leaves, is a coating of wax-like matter, about one-sixth of an inch thick, which is removed by the natives and employed in the manufacture of tapers. It contains, according to Vauquelin, two-thirds of a resinous substance and one-third of pure wax. Two kinds of wax

are collected in Brazil, one called *carnauba*,¹ from the leaves of the *Copernicia cerifera*, a palm, which forms large forests in the provinces

¹ *Carnauba Wax* is collected by cutting out the leaf buds, drying and beating them, and stirring the powder thus detached, in water. H. Stürke has stated as the result of an investigation that carnauba wax contains: a hydrocarbon, melting at 59° C.; an alcohol, $C_{27}H_{56}.OH$, melting at 76° C.; myricyl alcohol, $C_{30}H_{60}.OH$, melting at 85.5° C.; a diatomic alcohol, $C_{28}H_{56}.OH$, melting at 103.5° to 103.8° C.; an acid, $C_{24}H_{48}O_2$, isomeric with lignoceric acid, melting at 72.5° C.; an acid, $C_{27}H_{54}O_2$, isomeric with cerotic acid, melting at 79° C.; and an acid, or rather the lactone (anhydride) of an acid, $C_{10}H_{18}O_2$, $\left\{ \begin{array}{l} CH_2OH \\ COOH \end{array} \right.$, melting at 103.5° C., from which an acid, $C_{10}H_{18}(COOH)_2$, melting at 90° C. has been prepared. (Schædler, *Technol. der Fette und Öle*, 2te Auf., p. 884.) It is hard, brittle, and buff-colored, yellow, or greenish, resembling the resins more than wax, and melts at 84° C. (183.2° C.) which is much higher than the fusing point of other kinds of vegetable wax. "It takes a fine polish when rubbed with any soft material" does not receive impressions from the finger at the natural temperature of the hand, and is adapted for polishing furniture, either alone or mixed with wax. 2,000,000 pounds of it are said to be annually produced in Brazil, where it is largely used, mixed with tallow, in making candles, etc. (See also *P. J.*, 1904, 246.)

Under the name of *Ocotilla wax*, Helen Abbott Michael described (*A. J. P.*, Feb. 1885) a vegetable wax which she obtained from the bark of *Fouquieria splendens*, and believed to be a new variety. A wax which is said to be used, under the name of *Arbol de la Cera*, in Mexico not only for domestic purposes, but also as a remedy in diarrhœa and jaundice, is that obtained by boiling the fruit of the *Myrcia toledensis* in water. It is greenish or yellow, more brittle and unctuous than beeswax, has a feeble odor, a slightly bitter taste, and a density nearly equal to that of water, and melts at 43° C.; but on exposure the fusing point rises to 47.5° C. It is wholly soluble in boiling ether, insoluble in water, sparingly soluble in cold alcohol, and dissolves in twenty parts of boiling alcohol, depositing the greater part on cooling; alkalies saponify it readily. (*A. J. P.*, xv. 339, 1885.)

Pisang Wax from *Ficus cerifera*, according to Greshoff and Sack, occurs in white crystalline cakes, having the sp. gr. 0.963 to 0.970 at 15° C., and melting at 79° to 81° C. It is very sparingly soluble in ethyl alcohol, even when boiling, but readily soluble in boiling oil of turpentine, amyl alcohol, and carbon disulphide. Its acid number is 2 to 3, its saponification number 109. *Pisang-cerylic acid*, obtained by saponification, melts at 71° C., and has the composition $C_{24}H_{48}O_2$; while *pisang-cerylic alcohol*, which was also isolated, melts at 78° C., and has the formula $C_{23}H_{46}O$.

Gondang Wax occurs in brown pieces which are yellowish internally and have a sp. gr. of 1.015. In distinction from pisang wax, gondang wax is soluble in all the usual solvents at a boiling temperature, and it may be almost completely dissolved by prolonged boiling with ethyl alcohol, being however again deposited on cooling. Gondang wax purified in this way melted at 61° C., and yielded *fœco-cerylic acid* on saponification, which has the formula $C_{25}H_{50}O_2$, and melts at 57° C., while *fœco-cerylic alcohol* has the formula $C_{24}H_{48}O$, and melts at about 198° C. In its general character gondang wax is intermediate between wax and caoutchouc.—*Ph. Ztg.*, 1901, 563.

Japanese Wax has been imported into Europe in considerable quantities, either directly from Japan, or through the Chinese ports. It is obtained from the berries of the *Rhus succedaneum* of Linnaeus, and in small amount from the *R. sylvestris* and *R. vernicifera*, or lacquer plant. The partially dried berries are crushed, winnowed, steamed, placed in hemp cloth bags, steamed again, and pressed in a wooden wedge press. They yield about 15 per cent. of a coarse greenish tallowy mass. It has come in two forms, the one, as originally distinguished by Hanbury, of circular cakes, about four inches in diameter, and an inch thick, flat on one side and somewhat convex on the other; the second, as brought directly from Japan, of large rectangular blocks weighing, it may be, as much as 1 picul (133½ lbs.) which are packed in chests. It bears a considerable resemblance to purified beeswax, but is not quite so white, having a slightly yellowish tint, is softer, more friable, and has a somewhat rancid odor and taste. Its melting point is below that of wax, varying from 42° C. (107° F.) to 55° C. (131° F.). It is much more soluble in alcohol than is beeswax, is sa-

of Ceara, the other *ocuba*, from the fruit of a shrub of the province of Para (*J. P. C.*, 3e sér., v. 154). A form of vegetable wax sometimes seen in this country is that derived from *Myrica cerifera*, L., and commonly called *myrtle wax*. The wax *myrtle* is an aromatic shrub, from one to twelve feet high, growing in the United States, from New England to Louisiana, and flourishing especially on the sea coast. The fruit, which grows in clusters closely attached to the stems and branches, is small, globular, and covered with a whitish coat of wax, which may be separated for use. Other parts of the plant are said to possess medicinal virtues. The bark of the root is acrid and astringent, and in large doses emetic, and has been popularly employed in jaundice. The process for collecting the wax is simple. The berries are boiled in water, and the wax, melting and floating on the surface, is either skimmed off and strained, or allowed to congeal as the liquor cools, and then removed. To render it pure, it is again melted and strained, and cast into large cakes. It is collected in New Jersey, North Carolina, and New England, and particularly in Rhode Island.

Myrtle wax is of a pale grayish-green color, somewhat diaphanous, more brittle and unctuous to the touch than beeswax, of a feeble odor, and a slightly bitterish taste. It is about as heavy as water, and melts, according to G. E. Moore, at from 46.6° C to 48.8° C. (116° F. to 120° F.). It is insoluble in water, scarcely soluble in cold alcohol, soluble, excepting about 13 per cent., in twenty parts of boiling alcohol, which deposits the greater portion on cooling, soluble also in boiling ether, and slightly so in oil of turpentine. It is readily saponifiable with the alkalis. *Myrtle wax* is a mixture of glycerides and not a true wax. This variety of wax has been popularly employed in the United States as a remedy for *dysentery*; in which disease Fahnestock gave the powdered wax in doses of a teaspoonful frequently repeated, with alleged great advantage. (*Am. J. M. S.*, ii. 313.) It is occasionally substituted by apothecaries for beeswax in the formation of plasters, and is used in the preparation of tapers and candles. It is somewhat fragrant when burning, but emits a less brilliant light than common lamp oil.

CERATA.

CERATES

(ce-ră'tă)

Cérats, Céréolés, Elacocérolés, Fr.; Cerate, Wachs-salben, G.

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or rosin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and that of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should always be taken to select the oil or lard perfectly free from rancidity. In reference to the wax, too, there would seem to be a choice, as experience has shown that cerates made with yellow wax keep longer unchanged than those made with white or bleached wax, probably because there is in yellow wax some principle which corrects the tendency of fatty matters to become rancid. (F. Bringham, *A. J. P.*, 1869, 59.) The liquefaction should be effected by a very gentle heat, which may be applied by means of a water bath, and during the refrigeration the mixture should be well stirred, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the whole assumes the proper consistence, or, as some prefer, the melted cerate is allowed to cool quickly without stirring. When a large quantity is prepared, the mortar or other vessel into which the mixture may be poured for cooling should be previously heated by means of boiling water. It has been proposed to substitute paraffin for wax in the preparation of the cerates, but the great tendency to produce granulation in the finished cerate has largely prevented its use.

It is, we think, unfortunate that this class of preparations has been abandoned in the British Pharmacopœia, the several cerates having been rejected, or transferred to the class of ointments. Independently of the connection between the name and one of the characteristic constituents of the cerates, there is ground for difference between them and the ointments in their consistence, that of the cerates being such as to render them especially suitable for spreading on linen, while that of ointments

saponifiable with the alkalis, and is in the main a glyceride of palmitic acid with smaller amounts of the glycerides of stearic and arachidic acids. It has been employed in the preparation of candles, which yield as brilliant light as those made of common wax. It has been found useful in the preparation of cerates, etc. From Roucher's experiments it appears that there are two melting points of this wax, one corresponding closely with Procter's results, while the same wax rapidly heated to a point above that of fusion and then allowed to cool, if plunged into water at 42° C., melts into a transparent liquid; consequently melting at a point 12° C. below its freezing point in its ordinary state, which was 54° C.; the two temperatures being about equivalent in Fahrenheit's scale to 107° and 129°. (*P. J.*, Aug. 1872.)

is peculiarly adapted to inunction. W. H. Mieleke (*Ph. Cb.*, 1881, Nos. 20, 21) proposes a class of preparations, to which he has given the name "*Steatins*," "*Steatinum*." These are of about the consistence of cerates, of varied composition, and contain usually a considerable portion of tallow. The *Steatinum Iodoformi* offers a fair specimen of the class. "Take of mutton tallow 18 parts, expressed oil of nutmeg 2 parts, iodoform, in fine powder, 1 part. Melt the tallow and add the other ingredients." For other formulas, see *A. J. P.*, 1881, p. 404.

CERATUM. U. S.

CERATE [Simple Cerate]

(ce-ră'tŭm)

Ceratum Adipis, *U. S.* 1860; *Ceratum Simplex*, *U. S.* 1850; *Cérat Simple*, *Fr. Cod.*; *Unguentum cerum*, *P. G.*; *Einfaches Cerat*, *Wachssalbe*, *G.*; *Cerato simple*, *Sp.*

* "White Wax, *three hundred grammes* [or 10 ounces av., 255 grains]; White Petrolatum, *two hundred grammes* [or 7 ounces av., 24 grains]; Benzoinated Lard, *five hundred grammes* [or 17 ounces av., 279 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the white Wax, add the White Petrolatum, then the Benzoinated Lard, continuing the heat until the mixture is liquefied, and stir it constantly until it congeals. For use in southern latitudes, and during the heated season in other localities, *fifty grammes* [or 1 ounce av., 334 grains] of Benzoinated Lard may be replaced by an equal quantity of White Wax." *U. S.*

In the *U. S. Pharmacopœia* (8th Rev.) 20 per cent. of white petrolatum, and 50 per cent. of benzoinated lard are directed in place of the 70 per cent. of lard used in the *U. S. P.* 1890 process. The present official cerate will for these reasons remain free from rancidity a much longer time. In the preparation of this cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition, for the value of the preparation depends on its perfect blandness. To avoid change, it should be put up in small jars, and covered closely with tin foil so as to exclude the air. It is used for dressing *blisters*, *wounds*, etc., in all cases in which the object is to prevent the contact of air and preserve the moisture of the part and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose benzoinated lard should be used in winter, and simple ointment in summer, the cerate having too firm a consistence. George W. Sloan recommended the use of simple cerate as a pill excipient for certain oxidizable substances and special uses. (*Proc. A. Ph. A.*, 1884.)

CERATUM CAMPHORÆ. U. S.

CAMPHOR CERATE

(ce-ră'tŭm cām'phō-ræ)

Pommade Camphrée, *Fr. Cod.*; *Pomatum Camphoratum*, *Fr.*; *Kampfersalbe*, *G.*; *Pomada alcanforada*, *Pomatum camphoratum*, *Sp.*

* "Camphor Liniment, *one hundred grammes* [or 3 ounces av., 231 grains]; White Wax, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; White Petrolatum, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Benzoinated Lard, *four hundred grammes* [or 14 ounces av., 48 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the White Wax, add the White Petrolatum, then the Benzoinated Lard, and continue the heat until the mixture is liquefied. While the mixture is cooling, add the Camphor Liniment, and incorporate thoroughly by stirring until it congeals." *U. S.*

Camphor cerate now contains 2 per cent. of camphor; that of the *U. S. P.* 1880 contained only three-fifths of 1 per cent. This preparation was introduced in the *U. S. P.* 1880 primarily for use in making cerate of subacetate of lead by the extemporaneous process. It was subsequently found useful as a slightly stimulating dressing; hence the proportion of camphor was increased.

CERATUM CANTHARIDIS. U. S. (Br.)

CANTHARIDES CERATE

(ce-ră'tŭm cān-thăr'î-dīs)

Emplastrum Cantharidis, *Br.*; *Cantharides Plaster*; *Emplastrum Epispasticum*, *s. Vesicatorium*, *s. Vesicans*, *Emplastrum Lyttæ*; *Blistering Cerate* or *Plaster*; *Emplâtre Vesicatoire*, *Fr. Cod.*; *Pommade Epispastique*, *Emplâtre de Cantharides*, *Fr.*; *Emplastrum Cantharidum Ordinarium*, *P. G.*; *Spanisch-fliegen Plaster*, *Blasenpflaster*, *G.*; *Pomata di cantaridi*, *It.*; *Unguento de cantaridas*, *Sp.*

* "Cantharides, in No. 60 powder, *three hundred and twenty grammes* [or 11 ounces av., 126 grains]; Liquid Petrolatum, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Yellow Wax, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Rosin, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Lard, *one hundred and seventy grammes* [or 5 ounces av., 436 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Cantharides with the Liquid Petrolatum, and set the mixture aside, well covered, in a warm place, for forty-eight hours. Then add it to the Rosin, Yellow Wax, and Lard, previously melted and strained through muslin, and keep the mixture in a liquid condition by means of a water-bath, stirring occasionally, for one hour. Finally, remove it from the bath, and stir the mixture until it begins to congeal." *U. S.*

The *British Pharmacopœia* directs: Cantharides, in powder, $3\frac{1}{2}$ ounces (Imperial) or thirty-five grammes; Yellow Beeswax, Lard, and

Resin, each, 2 ounces (Imp.) or twenty grammes; and Soap Plaster, $\frac{1}{2}$ ounce (Imp.) or five grammes; melts the Resin, Soap Plaster, Wax, and Lard together; then introduces the Cantharides, mixes the whole thoroughly, and continues to stir the mixture while cooling. (See *Emplastrum Cantharidis*.)

This is the common well known *blistering plaster*. As it can be readily spread without the aid of heat, it is properly a cerate, and is, therefore, correctly named in the U. S. Pharmacopœia. The process now official differs from that of previous Pharmacopœias in the substitution of liquid petrolatum for oil of turpentine; the previous maceration of the cantharides with this solvent has for its object the softening and extraction of the cantharidin; the present cerate is somewhat firmer in consistence than that made by the U. S. P. 1890.

There can be no question of the advantage of retaining the cantharides in contact with hot liquefied fatty bodies to facilitate the extraction of the cantharidin. The cerate is essentially the same as prepared by the two processes, though the U. S. formula has a decided advantage over the British, in keeping the mixture of the flies and the other ingredients for some time at an elevated temperature, while in the latter they are allowed to cool after being mixed with the fatty substances. Care was formerly considered requisite, in making the cerate, not to injure the flies by heat; it was therefore recommended that they should not be added to the other ingredients until immediately before these begin to stiffen, after having been removed from the fire; and, though this direction has been omitted, no provision is made for the continued application of heat.

From the experiments of Donovan, and those of Procter (*A. J. P.*, xiii. 302 and xxiv. 296), it may be inferred that the vesicating principle of Spanish flies is not injured or dissipated by a heat under 148.8° C. (300° F.), and that a limited elevated temperature, instead of being hurtful, is positively advantageous in the preparation of the cerate. The cantharidin is thus more thoroughly dissolved by the oleaginous matter, and consequently brought more efficiently into contact with the skin, than when retained in the interior of the tissue of the fly. Another advantage, stated by Donovan, is that the moisture usually existing to a certain extent in all the ingredients of the cerate is thus dissipated, and the preparation is less apt to become mouldy, or otherwise to undergo decomposition. Instead, therefore, of waiting until the melted wax, resin, and lard begin to stiffen, it is better to add the powder before the vessel is removed from the fire. Donovan recommends that, as soon as the other ingredients are melted, the powdered flies should be added, and the mixture stirred until the heat is shown by a thermometer to have risen to 121.1° C. (250° F.), when the vessel is to be removed from the fire, and the mixture stirred constantly until cool. At the heat mentioned,

ebullition takes place in consequence of the escape of the moisture contained in the materials. In the cerate thus prepared, the active matter has been dissolved by the lard, and the powder may be separated, if deemed advisable, by straining the mixture before it solidifies. Care should be taken that the temperature be not so high as to decompose the ingredients; and it would be better to keep it within 100° C. (212° F.), by means of a water bath, as in the U. S. process, than to incur any risk from its excess. Violent irritation and even vesication of the face of the operator are stated to have resulted from exposure to the vapors of the liquid, at a temperature of 121.1° C. (250° F.). (*P. J.*, ii. 391.) From an experiment, however, of Procter, it appears that, though cantharidin begins to volatilize slightly at 121.1° C. (250° F.), and rapidly rises in vapor and sublimates at from 205.5° C. to 211.1° C. (402° F. to 412° F.), yet it is not decomposed unless by increasing the heat considerably above the last-mentioned point. (*A. J. P.*, xxiv. 296 and 298.) Dieterich states that the activity is greatly increased by the use of acid in the manufacture. Thus, for every 250 Gm. of powdered flies used he adds to the melted mass 1 Gm. sulphuric acid and 10 Gm. alcohol (90 per cent.), keeps the mass for two hours at 70° C., and finally adds 2 Gm. barium carbonate rubbed up with 6 Gm. alcohol. (*Ph. Centralh.*, 1892, 425.) It is desirable that the flies should be very finely pulverized. Coarsely powdered cantharides should not be used, because of the imperfect and unequal distribution of the vesicating agent. Powdered euphorbium is said to be sometimes fraudulently added.

Uses.—The cerate will raise a blister in ordinary conditions of the system, if the flies are good, and not injured in the preparation. It should be spread on soft leather, though linen or even paper will answer the purpose when leather is not to be had. An excellent mode of preparing it for use is to spread a piece of leather, of a proper size, first with adhesive plaster, and afterwards with the cerate, leaving a margin of the former uncovered, in order that it may adhere to the skin. Heat is not requisite, and should not be employed in spreading the cerate. Some sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but, if the flies originally employed were good, this addition is superfluous. The practice of applying over the surface with a brush an ethereal tincture of cantharides, which leaves a thin coating of extract, renders the preparation more certain.

Previous to the application of the plaster, the skin should be moistened with warm vinegar or other liquid. In adults, when the full action of the flies is desired, and the object is to produce a permanent effect, the application should be continued for eight hours, and on the scalp for twelve hours. In very delicate persons, however, or those subject to strangury, or upon

parts of a loose texture, or when the object is merely to produce a blister to be healed as quickly as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a flaxseed poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum. In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied, and from two to four hours are usually sufficient for any desirable purpose. When the head, or other hairy part, is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster, so that the abrasions may heal, and some impediment be offered to the absorption of the cantharidin. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but, if it be desirable to maintain the discharge for a short time, rosin cerate should be used, and the cuticle removed if it can be done without inconvenience. When it is wished that the blistered surface should heal as soon as possible, Goulard's cerate should be freely applied. The effects of an issue may be obtained by employing savin ointment, or the ointment of Spanish flies, as a dressing. If much inflammation takes place in the blistered surface, it may be relieved by emollient poultices, weak lead water, or Goulard's cerate. When there is an obstinate indisposition to heal, we have found nothing so effectual as zinc ointment with two to four grains of phenol to the ounce.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil, and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting *blistering cloth*, *blistering paper*, *vesicating taffeta*, etc. The advantages of these preparations are that they occupy less space, are more portable, and, being very pliable, are more easily adapted to irregularities of the surface. Absolutely pure cantharidin is expensive and not requisite,¹ as extracts of cantharides, made with ether, alcohol, or boiling water, will answer every purpose. Henry and

Guibourt give the following formula. Digest powdered cantharides in ether, distil off the ether, evaporate the residue by means of a salt water bath, until ebullition ceases, melt the mass which remains, with twice its weight of wax, and spread the mixture upon waxed cloth. The *waxed cloth* may be prepared by spreading upon linen or muslin a mixture composed of 8 parts of white wax, 4 of olive oil, and 1 of turpentine, melted together. An extract of cantharides of a buttery consistence, said to act very efficiently when applied by means of paper greased with it, is prepared by digesting 4 parts of flies with one part of strong acetic acid and 16 of alcohol, straining, filtering, and evaporating at a moderate heat. *A cerate of the extract of cantharides* was formerly official (see U. S. D., 18th ed., p. 358.)

A preparation which received the favorable report of a committee of the Society of Pharmacy, at Paris, is the following, proposed by Dubuisson. Four parts of a hydro-alcoholic extract of the flies, made by maceration, are mixed with an aqueous solution of one part of pure gelatin, so as to obtain a solution of suitable consistence, which is then applied upon a piece of stretched waxed cloth, care being taken that the strokes of the brush should always have the same direction. When the first layer has dried, a second and a third are to be applied in the same manner. The gelatin renders the plaster more adhesive and gives consistence. The hydro-alcoholic extract is preferred to the alcoholic, because it contains less of the green oil, which does not readily mix with the other ingredients. The committee, however, preferred the aqueous extract, as cheaper and more active. This taffeta has been tried, and found to raise blisters in four hours. (*J. P. C.*, 3e sér., viii. 67.) For very speedy vesication, an infusion of the flies in strong acetic acid is sometimes employed. None of these preparations are likely to supersede the cerate, but the demand for them was met by introducing into the Pharmacopœia of 1880 *Charta Cantharidis* and *Collodium Cantharidatum* in subsequent pharmacopœias.

CERATUM PLUMBI SUBACETATIS.

U. S. (Br.)

CERATE OF LEAD SUBACETATE [Goulard's Cerate]

(cē-rā'tūm plūm'bī sūb-āc-ē-tā'tis)

Unguentum Glycerini Plumbi Subacetatis, Br.; Unguentum Plumbi Subacetatis Compositum; Compound Ointment of Subacetate of Lead, Ointment of Glycerin of Lead Subacetate; Ceratum cum Subacetate Plumbico; Cérat Saturné, *Fr. Cod.*; Cérat de Goulard, *Fr.*; Unguentum Plumbi, *P. G.*; Bleisalbe, *Bleicerat, G.*; Pomato con acetato basico di piombo, *Unguento saturnino, It.*; Cerato de saturno, *Sp.*

¹ Dragendorff (*A. J. P.*, 1872, p. 273) recommends *sodium cantharidate*. M. E. Delpech (*A. J. P.*, xlii. 240) proposes the use of *potassium cantharidate* in substance or solution. He prepares it by dissolving two parts of cantharidin in 150 parts of alcohol, and adding 1.6 parts of potassium hydroxide dissolved in a very little water. The whole becomes a crystalline mass, from which the alcohol may be separated by pressure. See also R. Rother, *Ch. Ph.*, Nov. 1872.

* "Solution of Lead Subacetate, twenty grammes [or 309 grains]; Wool-Fat, twenty grammes [or 309 grains]; Paraffin, twenty grammes [or 309 grains]; White Petrolatum, thirty-eight

grammes [or 1 ounce av., 150 grains]; Camphor, two grammes [or 31 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. To the melted Wool-Fat in a warm mortar gradually add the Solution of Lead Subacetate, and incorporate it by slow trituration. To the mixture add the White Petrolatum and Paraffin, previously melted, and in which the Camphor has been dissolved; mix thoroughly until homogeneous." *U. S.*

The British Pharmacopœia makes an ointment by mixing glycerin of subacetate of lead with soft and hard paraffin together. (See *Unguentum Glycerini Plumbi Subacetatis*; also *Glycerinum Plumbi Subacetatis*.)

The process for this cerate has been greatly improved in the *U. S. P.* (8th Rev.) by eliminating the fatty ingredients (lard and cotton seed oil) used in making the camphor cerate of the previous pharmacopœia; white petrolatum, wool-fat and paraffin are now used, and this change removes the great objection to the former official cerate, of proneness to rancidity, and discoloration. F. A. Haussmann (*A. J. P.*, 1897, 575) suggested the use of hydrated wool-fat in place of the camphor cerate; the new official process requires anhydrous wool-fat. This cerate received the name by which it is commonly known from Goulard, by whom it was employed and recommended.

Uses.—It is used chiefly in *excoriations*, *burns*, *scalds*, and *chilblains*, and in *cutaneous eruptions*. Wherever there is an acute active inflammation of the skin it is a most efficient remedy.

CERATUM RESINÆ. U. S. (Br.)

ROSIN CERATE [Basilicon Ointment]

(cē-rā'tūm rē-sī'næ)

Unguentum Resinæ, Br.; Ointment of Resin, *Unguentum Basilicum*; *Unguentum Tetrapharmacum*; Resin Ointment, Resin Cerate; Oungent Basilicum, *Fr. Cod.*; Cérat de Résine Anglaise, *Fr.*; Harzcerat, Harzsalbe, Königsalbe, Zugsalbe, *G.*

* "Rosin, three hundred and fifty grammes [or 12 ounces av., 151 grains]; Yellow Wax, one hundred and fifty grammes [or 5 ounces av., 127 grains]; Lard, five hundred grammes [or 17 ounces av., 279 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the Rosin, add the Yellow Wax and the Lard, and continue the heat until liquefied, then strain the liquid through muslin, and allow it to congeal with occasional stirring. In cold weather five hundred and thirty grammes [or 18 ounces av., 304 grains] of Lard, and one hundred and twenty grammes [or 4 ounces av., 102 grains] of Yellow Wax may be used." *U. S.*

"Take of Resin, Yellow Beeswax, and Olive Oil, each 8 ounces (Imperial) or 200 grammes; Lard, 6 ounces (Imp.) or 150 grammes. Add the Lard and Olive Oil to the previously melted Resin and Beeswax; strain; stir until cold." *Br.*

The *U. S.* preparation does not differ greatly from that formerly official except that occasional stirring while congealing is directed; the *U. S. P.* 1890 process forbade stirring. The British process (1898) discards the simple ointment and almond oil previously used (1885), and substitutes lard and olive oil. Rosin cerate, commonly called *basilicon ointment*, is much used as a gently stimulating application to *blistered surfaces*, *indolent ulcers*, *burns*, *scalds*, and *chilblains*. We have found no application more effectual in disposing the *ulcers* which follow *burns* to heal.

Off. Prep.—Linimentum Terebinthinæ, *U. S.*

CERATUM RESINÆ COMPOSITUM. U. S.

COMPOUND ROSIN CERATE [Deshler's Salve]

(cē-rā'tūm rē-sī'næ cōm-pōs'it-tūm)

Cérat de Résine Composé, *Fr.*; Zusammengesetzte Harzsalbe, *G.*

* "Rosin, two hundred and twenty-five grammes [or 7 ounces av., 410 grains]; Yellow Wax, two hundred and twenty-five grammes [or 7 ounces av., 410 grains]; Prepared Suet, three hundred grammes [or 10 ounces av., 255 grains]; Turpentine, one hundred and fifteen grammes [or 4 ounces av., 25 grains]; Linseed Oil, one hundred and thirty-five grammes [or 4 ounces av., 333 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the Rosin, Yellow Wax, Turpentine, and Prepared Suet; to this add the Linseed Oil, and continue the heat until the mixture is liquefied; then strain it through coarse muslin, and stir it until it begins to congeal." *U. S.*

Compound rosin cerate was introduced into the *U. S. P.* (8th Rev.) because of its continued use in some parts of the country; it was official in the *U. S. P.* 1870. Owing to the presence of linseed oil it has a tendency to become tough in consistence on keeping; but the peculiar consistence has been urged as one of its advantages. It is used for the same purposes as rosin cerate; see *Ceratum Resinæ*.

CERII OXALAS. U. S., Br.

CERIUM OXALATE [Ceraus Oxalate]

(cē'ri-i ōx'ā-lās)

"Cerium Oxalate consists chiefly of a mixture of the oxalates of cerium, didymium, and lanthanum, and of other rare earths of this group." *U. S.* "Cerium Oxalate, $\text{Ce}_2(\text{C}_2\text{O}_4)_3 \cdot 9\text{H}_2\text{O}$, may be obtained by interaction of a soluble cerium salt and a soluble oxalate. It usually contains some lanthanum oxalate and didymium oxalate." *Br.*

Oxalate of Cerium; Cerium Oxalicum, Oxalas Cericus; Oxalate de Cérium, *Fr.*; Oxalsäures Ceroxylid, Cerium Oxalat, Ceroxalat, *G.*

Cerium is a metal, which was discovered in 1803 by Berzelius and Hisinger, and about the same time by Klaproth, who, however, described it as an earth. By the two former chemists it was recognized as a metal, and named cerium in honor of the goddess Ceres. It was obtained from a Swedish mineral, formerly from its great weight called *heavy stone of Bastnas* (*Bastnas Schwerstein*), but now named *cerite*, after the metal extracted from it. Besides *cerite*, it has been found in several other minerals, as *gadolinite*, *orthite*, and *monazite*, etc. It is not easy to obtain it pure in the metallic state, as its oxides and salts are difficult of reduction. Berzelius describes it as in the form of pulverulent masses, of a deep chocolate-brown, which exhibit, however, under the burnisher a metallic appearance and a dark gray color. Hildebrand and Norton have since prepared it in large quantity by the electrolysis of its chloride. It is a bad conductor of electricity. Heated in the air it takes fire before the point of ignition, and burns vividly, passing to the state of peroxide. At ordinary temperatures it is oxidized in a moist atmosphere, giving out a strong and disagreeable odor. In water, especially when moderately heated, it rapidly oxidizes, with the evolution of hydrogen and the water does not become alkaline. There are two cerium oxides formerly considered as the protoxide and sesquioxide. (According to more recent investigators, cerium forms a sesquioxide and a dioxide only, so that cerous oxalate, which is the official salt, is an oxalate of the sesquioxide, a fact recognized in the Pharmacopœia of 1880.) Sulphur and phosphorus combine with it. Of its compounds two only have been introduced into medicine, the nitrate and the oxalate.

Cerium oxalate may be obtained from *cerite*, and F. F. Mayer gave a process for the purpose, of which the following is an outline. The mineral consists of cerium, lanthanum, and didymium silicates, with numerous other substances in smaller proportion, the cerium oxide constituting about 39 per cent. of the whole. The powdered mineral is made into a paste with sulphuric acid, and then heated over a lamp until the mass ceases to swell and no longer absorbs sulphuric acid very cautiously added. Upon the cooling of the mass, it is powdered, and exposed in a crucible to the heat of an anthracite fire until it assumes a pale brownish-red color. It is now lixiviated first with hot water and then with nitric acid, and the solution treated with hydrogen sulphide in order to get rid of various metals by precipitation. To the clear liquid some hydrochloric acid is first added, and then a solution of oxalic acid, the former of which holds in solution the calcium oxalate produced, the latter throws down cerium oxalates and oxalates of other metals. The precipitate, having been washed with warm water, is formed into a paste with a quantity of magnesium car-

bonate equal to half that of the mineral employed; and the paste is dried on porous fire brick, finely powdered, and calcined until it becomes of a cinnamon color. It now contains all of the cerium in the form of *ceroso-cerie oxide*. To separate this the mass is treated with an excess of nitric acid, the solution evaporated to get rid of the excess of acid, then diluted with warm water, and lastly poured into a vessel containing boiling water acidulated with a little more than half of one per cent. of sulphuric acid. A yellow precipitate of basic cerium sulphate is formed, while a little of the neutral sulphate, and all the lanthanum and didymium, remain dissolved. The precipitate is now dissolved in stronger sulphuric acid, the solution digested with a few crystals of sodium thiosulphate, in order to reduce the *ceroso-cerie oxide* to cerous oxide, and the liquid, having been filtered, is treated with solution of oxalic acid, which causes a precipitate of cerium oxalate. This is washed with warm water, and dried. (*A. J. P.*, 1860, p. 4.)

The cerium compounds were formerly obtained chiefly from *cerite*, which occurs in considerable amounts in Sweden, and affords at least 50 per cent. of *cerium oxide*. The thorium salts were obtained from the mineral *thorite*, which is found in Norway, and contains about 60 to 70 per cent. of its peculiar earth. According to O. N. Witt, it was soon found that the supplies of *thorite* were not sufficient to even approximately meet the demand for thorium salts required for the incandescence gas mantle industry. A new source of supply was therefore sought for, and this has been found in the mineral *monazite*, which occurs in considerable quantities in North Carolina and in the Province of Bahia, in Brazil. It is from the latter source that the German industries now chiefly draw their supplies. *Monazite* is a cerous phosphate, in which a portion of the cerium is replaced by the other *cerite* earths. The thorium earth is not an integral constituent of the mineral, and, although quite regularly admixed with it, its amount varies within very broad limits. It is further stated by Witt that the *monazite* from Bahia contains at the most from 5 to 6 per cent. of thorium earth, while the earths of the *cerite* group amount to from 50 to 60 per cent. or more, of which about one-half is cerium itself. The occurrence of these two earths in nature is therefore in inverse proportion to the requirements for industrial purposes. As enormous quantities of *monazite* have to be worked up in order to obtain the necessary supplies of thorium salts, and as only a very small proportion of the *cerite* earths which are obtained at the same time can be utilized in the form of cerium nitrate, it is evident that these must accumulate in considerable amounts. It has thus become an important problem, upon which technical chemists have been engaged for some time, to devise a

practical method for the separation of the cerite earths, with the hope that they might then find some industrial applications for which the complex mixtures now available are not adapted. From the existing conditions of this industry, as briefly outlined, it may be inferred that the cerium oxalate of commerce, which, although used medicinally, likewise consists of such a complex mixture of the oxalates of cerium, lanthanum, and didymium, is at present more or less a by-product in the manufacture of thorium salts. See Power and Shedden, on the Composition and Determination of Cerium Oxalate (*J. Soc. Chem. Ind.*, xix. No. 7; also *Ph. Ztg.*, 1902, 297).

Properties.—It is officially described as “a fine, white powder, without odor or taste, and permanent in the air. Insoluble in water, alcohol, ether, or in solutions of potassium or sodium hydroxide; insoluble in cold, but soluble in hot, diluted sulphuric or hydrochloric acid. When heated to redness it is decomposed, leaving a residue of reddish-brown ceric and other rare-earth oxides, constituting not less than 47 per cent. of the salt. On boiling the salt with potassium hydroxide T.S., an insoluble residue of white hydroxides is produced; if the filtrate from this residue be supersaturated with acetic acid, the addition of calcium chloride T.S. will produce a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. If the residue left after heating Cerium Oxalate be dissolved in concentrated sulphuric acid, and a small crystal of strychnine added, a deep blue color will appear, which will rapidly change to purple and then to red. From the solution in diluted hydrochloric or sulphuric acid, potassium hydroxide T.S. precipitates white hydroxides, which do not redissolve in an excess of the reagent, and gradually turn yellow in contact with air. Ammonium carbonate T.S. precipitates from the same solution white cerous and other rare-earth carbonates, which are somewhat soluble in an excess of the reagent. If 0.1 Gm. of Cerium Oxalate be dissolved in 1 Cc. of sulphuric acid, and 2 Cc. of potassium sulphate T.S. be added, small, colorless crystals of cerium and other rare-earth potassium sulphates will, after some time, be deposited. No effervescence should occur when the salt is dissolved in diluted hydrochloric acid (absence of carbonates). The solution of the salt (1 in 20) in diluted hydrochloric acid should not respond to the Time-Limit Test for heavy metals, omitting the addition of the ammonia water (see PART III, Test No. 121). Five Cc. of the solution of the salt (1 in 10) in diluted hydrochloric acid should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17). On boiling the salt with potassium hydroxide T.S. and filtering, no precipitate should be produced in the filtrate by the addition of either ammonium chloride T.S. (absence of aluminum) or ammonium sulphide T.S. (absence of zinc).” *U. S.* As usually seen in commerce it has a pinkish

tinge, due to the presence of a trace of a compound of didymium. The British Pharmacopœia states that it is “an almost white granular powder, insoluble in water, decomposed at a dull red heat, yielding a reddish-brown powder which dissolves completely and without effervescence in boiling hydrochloric acid; the resulting solution gives with a saturated solution of potassium sulphate a white crystalline precipitate. When incinerated it loses 53 per cent. in weight. It should yield no characteristic reaction with the tests for arsenium, iron, aluminium, zinc, calcium, carbonates, or phosphates.”

Uses.—Cerium oxalate is supposed to act in a manner very similar to bismuth subnitrate. It was originally brought forward by Sir James Y. Simpson as a remedy in the vomiting of pregnancy, and has been extensively used in this affection, and also in gastric disturbances of various diseases, such as phthisis, uterine disorder, hysteria, dyspepsia, pyrosis, etc. To a less extent it has been used in intestinal inflammatory diseases. Simpson also considered it to be a good nervine tonic, and used it with asserted great advantage in chorea.

Cerium nitrate has also been employed, though not official. Simpson believed it to be a nerve tonic, and also useful in irritable dyspepsia and chronic vomiting. The dose is the same as that of the oxalate, though it would be prudent to begin with a smaller quantity, as, being a soluble salt, it might be more disposed to irritate in overdoses.

Dose, of either the oxalate or nitrate, one grain (0.065 Gm.), doubled if necessary, and repeated three times a day, or more frequently if a return of the vomiting should seem to require it. It may be given in pill or suspended in water.

CETACEUM. U. S., Br.

SPERMACETI

(ce-tă'ce-ŭm)

“A peculiar, concrete, fatty substance, obtained from the head of the sperm whale, *Physeter macrocephalus* Linné.” *U. S.* “A concrete fatty substance, obtained, mixed with oil, from the head of the Sperm Whale, *Physeter macrocephalus*, Linn. It is separated from the oil by filtration and pressure, and is afterwards purified.” *Br.*

Blanc de Baleine ou Cétine. *Fr. Cod.*; Spermaceti, Cétine, Ambre Blanc, *Fr.*; Cetaceum, *P. G.*; Walrat, Wallrath, Spermaceti, *G.*; Cetina, Spermaceti, *It.*; Esperma de ballena, Sperma ceti, *Sp.*

The spermaceti whale is from sixty to eighty feet long, with an enormous head, not less in its largest part than thirty feet in circumference, and constituting one-third of the whole length of the body. The upper part of the head is occupied by large cavities, separated by cartilaginous partitions, and containing an

oily liquid, which, after the death of the animal, concretes into a white spongy mass consisting of spermaceti mixed with oil. This mass is removed, and the oil allowed to separate by draining. The crude spermaceti obtained from a whale of the ordinary size is more than sufficient to fill twelve large barrels. It still contains much oil and other impurities, from which it is freed by expression, washing with hot water, melting, straining, and repeated washing with a weak boiling potash lye. Common whale oil and the oil of other cetaceous animals contain small quantities of spermaceti, which they slowly deposit on standing.¹

Properties.—Spermaceti is officially described as in "white, somewhat translucent, slightly unctuous masses of a scaly, crystalline fracture and a pearly lustre, with a very faint odor and a bland, mild taste. It becomes yellowish and rancid on prolonged exposure to air. Specific gravity: 0.938 to 0.944 at 25° C. (77° F.), 0.842 at 100° C. (212° F.). Melting point: 45° to 50° C. (113° to 122° F.). Insoluble in water and nearly so in cold alcohol; soluble in about 50 parts of boiling alcohol; also in ether, chloroform, carbon disulphide, fixed and volatile oils; only slightly soluble in cold petroleum benzin. An alcoholic solution of Spermaceti is neutral to litmus paper. If 1 Gm. of Spermaceti be boiled with 1 Gm. of anhydrous sodium carbonate and 50 Cc. of alcohol, and the mixture cooled and filtered, the filtrate, upon being supersaturated with acetic acid, may become turbid, but it should not afford a precipitate (absence of *stearic acid*.)" *U. S.* The British Pharmacopœia states that "it is reducible to powder by the aid of a little alcohol (90 per cent.). It is insoluble in water, and nearly insoluble in cold alcohol (90 per cent.), but soluble in ether, chloroform, boiling alcohol (90 per cent.), and in fixed and volatile oils. Melting point 114.8° to 122° F. (46° to 50° C.) when tested by the method described under 'Cera Flava.' 0.2 gramme dissolved, by the aid of a water-bath, in 20 cubic centimetres of alcohol (90 per cent.), two drops of solution of phenol-phthalein being added, should not require more than one drop of volumetric solution of sodium hydroxide to produce a permanent red color (limit of acidity). Boiled with alcohol (90 per cent.), and the mixture cooled and filtered, the filtrate should not afford a flocculent precipitate on the addition of water (absence of stearic acid)." *Br.* As found

in commerce it is not chemically pure, containing a fixed oil, and often a peculiar coloring principle. From these it is separated by boiling in alcohol, which on cooling deposits it in crystalline scales. Thus purified, it does not melt under 49° C. (120° F.), is soluble in 40 parts of boiling alcohol of the sp. gr. 0.821 (Thénard), and is harder, more shining, and less unctuous than ordinary spermaceti. Spermaceti is a mixture of various fats. When recrystallized from alcohol as just described, the purified *cetin* is obtained, while the alcohol on evaporation deposits an oil (mechanically admixed sperm oil). The cetin which crystallizes out of the alcohol is essentially *cetyl palmitate*, $C_{15}H_{33}(C_{15}H_{31}O_2)$,—that is, a compound of *cetyl alcohol* (*ethyl* of Chevreul), $C_{15}H_{33}.OH$, and *palmitic acid*, $C_{15}H_{31}O_2$. According to Heintz, however, there are small amounts of other fats with the cetin; fats containing the acids *stearic*, $C_{17}H_{35}O_2$, *myristic*, $C_{14}H_{29}O_2$, and *lauro-stearic*, $C_{17}H_{33}O_2$, and the alcohol radicals corresponding to these acids.

L. F. Kebler, after examining about twenty samples of spermaceti, found that commercial specimens have a melting point of from 42° to 47° C., a specific gravity ranging from 0.905 to 0.945 at 15° C., and saponification numbers from 125.8 to 134.6. (*A. J. P.*, 1896, 7, and 1897, 104.)

Uses.—Spermaceti has been given as a demulcent in irritations of the mucous membrane; but it has no remedial properties. It may be reduced to powder by the addition of a little alcohol or almond oil, or by melting it at a very low heat, pouring into a warm mortar, and agitating it until perfectly cold; an emulsion may be made by mixing spermaceti first with half its weight of olive oil, then with powdered gum arabic, and lastly with water. Spermaceti Cerate (*Ceratum Cetacei*, *U. S.* 1890) was made by melting together 10 parts of spermaceti and 35 parts of white wax and then adding 55 parts of warmed olive oil.

Off. Prep.—Unguentum Aquæ Rosæ, *U. S.*, *Br.*; Unguentum Capsici, *Br.*; Unguentum Cetacei, *Br.*

CHARTA SINAPIS. *U. S.*, *Br.*

MUSTARD PAPER

(châr'ta sî-nâ'pîs)

Sinapisme en feuille. *Fr. Cod.*; Papier Moutarde, *Papier Sinapisé, Fr.*; Charta sinapisata, *P. G.*; Senfpapier, *G.*; Carta senapata, *It.*; Papel sinapico, *Charta sinapica, Sp.*

* "Black Mustard, in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains]; Rubber, ten grammes [or 154 grains]; Petroleum Benzin, Carbon Disulphide, each, a sufficient quantity. Pack the Black Mustard in a conical percolator, and gradually pour Petroleum Benzin upon it until the percolate ceases to produce a permanent, greasy stain upon

¹According to W. Gilmour, sperm oil should contain not less than 4 per cent. of cetin, and if much less be obtained by the following process, adulteration has been practised. Shake one part by weight of sulphuric acid (sp. gr. 1.84) with four parts of the oil; allow to stand 20 minutes, shaking twice; add 3 parts of distilled water; shake this thoroughly, and allow to stand from 16 to 20 hours; dilute with 3 or 4 times its volume of distilled water; agitate thoroughly. On standing, the cetin floats upon the top, and can readily be skimmed off, washed, dried, and weighed. (*P. J.*, vii. 328. See also *Chem. Ztg.*, 1893, 1456, and *Am. Drug.*, 1895, 105.)

blotting paper. Remove the powder from the percolator, and dry it by exposure to the air. Having meanwhile dissolved the Rubber in a mixture of *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], each, of Petroleum Benzin and Carbon Disulphide, mix the purified Mustard with a sufficient quantity of the solution to produce a semi-liquid magma, and apply this, by means of a suitable brush, to one side of a piece of rather thick, well-sized paper, so as to cover it completely, and then allow the surface to dry. A surface of sixty square centimeters should contain about 4 Gm. of Black Mustard deprived of oil. Before it is applied to the skin, Mustard Paper should be dipped in warm water for about fifteen seconds." *U. S.*

"Black and White Mustard Seeds, equal proportions by weight; Benzol, Solution of India-rubber, of each, a sufficient quantity. Bruise the Mustard Seeds and extract the fixed oil by percolation with the Benzol. Dry the residue by exposure to the air in a warm closet, and reduce to No. 60 powder. Mix seventy-five grains (or five grammes) of the purified mustard with five fluid drachms (or eighteen cubic centimeters) of Solution of India-rubber, and spread by means of a suitable brush over about 30 square inches (or about two square decimetres) of one side of a piece of cartridge paper. Allow it to dry by exposure to the air." *Br.*

The formula for this preparation was greatly improved by the *U. S. P.* in 1890 and *Br.* 1898. The British preparation (1885) was at fault in not providing for the extraction of the fixed oil by previously percolating with petroleum benzin or carbon disulphide; otherwise the paper will be greasy, giving to the plaster an untidy appearance and soiling the linen of the patient. Solution of gutta-percha is unsuited for use in this preparation, on account of want of adhesiveness, and the tendency of the mixture, when dry, to crack and peel off. We have used instead a solution of 1 part of pure rubber in 30 of equal parts of carbon disulphide and petroleum benzin. On the large scale, by means of a plaster spreading apparatus a uniform coat of this solution may be applied to paper. As the latter passes out from under the apparatus, a sieve containing the powdered mustard is shaken over it; this is fixed by the adhesive coat and firmly retained after the evaporation of the volatile liquids in a warm place. The application of the powdered mustard must be properly regulated according to the speed with which the machine delivers the coated paper. The paper is cut into pieces of convenient size, and needs only to be wetted with tepid water to be ready for use. Owing to the fact that the large manufacturers can put mustard paper upon the market at such low rates that it pays the apothecary better to buy than to prepare it, Charta Sinapis, so far as we can learn, is rarely made in the retail stores. Experience

has shown that the ready-made mustard papers err rather from too much than from too little activity. Moreover, their action cannot be regulated with the same nicety as can that of the mustard poultice. Unless in the case of travellers, and of others who must wait upon themselves, the domestic application is preferable. The *mustard leaves* can rarely be borne for more than ten or fifteen minutes. For the medicinal uses of mustard paper see *Sinapis*; care should be observed to protect the leaves, as they are popularly called, from the action of moist air by keeping them in well closed tinned iron containers.

CHARTÆ.

PAPERS

(châr'tæ)

Papiers Sparadrapiques, *Fr.*; Medicamentlrte Papiere, *G.*

This class of preparations, long official in the French Codex, was afterwards adopted into the British Pharmacopœia, but was not introduced into that of the United States until 1870.¹

CHIMAPHILA. U. S.

CHIMAPHILA [Pipsissewa]

(chî-măph'î-lă)

"The dried leaves of *Chimaphila umbellata* (Linné) Nuttall (Fam. *Ericaceæ*)." *U. S.*

Prince's Pine, Wintergreen; Bitter Wintergreen, King's Cure, Ground Holly, Love-in-winter, Rheumatism Weed; Herbe de Pyrole ombellée, *Fr.*; Doldenblütiges Harnkraut, Wintergrün, *G.*

¹ *Charta Cantharidis*.—A blistering paper was formerly recognized by the two Pharmacopœias, *Charta Cantharidis*, *U. S.*, *Charta Epispastica*, *Br.*; but as these preparations were found inefficient, they have been very properly dropped from the official lists. The United States process (1880) is as follows: "White Wax, eight parts [or four ounces av.]; Spermaceti, three parts [or one and a half ounces av.]; Olive Oil, four parts [or two fluidounces]; Canada Turpentine, one part [or half an ounce av.]; Cantharides, in No. 40 powder, one part [or half an ounce av.]; Water, ten parts [or five fluidounces]. Mix all the substances in a tinned vessel, and boil gently for two hours, constantly stirring. Strain through a woolen strainer without expressing, and, by means of a water-bath, keep the mixture in a liquid state in a shallow, flat-bottomed vessel with an extended surface. Coat strips of sized paper with the melted plaster, on one side only, by passing them successively over the surface of the liquid; when dry, cut the strips into rectangular pieces." *U. S.* 1880.

Charta Potassii Nitratis, *U. S.* 1890. (*Potassium Nitrate Paper*).—"Potassium Nitrate, two hundred grammes [or 7 ounces av., 24 grains]; Distilled Water, eight hundred cubic centimeters [or 27 fluidounces, 24 minims]. Dissolve the Potassium Nitrate in the Distilled Water. Immerse strips of white, unsized paper in the solution, and dry them. Keep the paper in well-closed vessels." *U. S.* 1890. This preparation is identical with the *Charta Nitrata* of the German Pharmacopœia; it is sometimes called *asthma paper*. Care should be taken to dissolve thoroughly all the nitrate, so that it shall not be deposited upon the paper in large particles and interfere with slow and steady combustion. This paper is an excellent remedy, which in many cases of *asthma* affords much relief. It is used by burning in front of the patient, who inhales its fumes. Its efficacy is much increased by saturating it with fluidextract of belladonna and drying. Paper thus prepared must be used with some caution.

The genus *Chimaphila* was separated from *Pyrola* by Pursh. It embraces two American species, *C. umbellata* and *C. maculata*, known by the common title of *wintergreen*. The generic title is formed of two Greek words, *χείμα*, winter, and *φίλος*, a friend.

Chimaphila umbellata, Barton, *Med. Bot.*, i. 17; Carson, *Illust. of Med. Bot.*, i. 62, pl. 53. — *Pyrola umbellata*, Willd., *Sp. Plant.*, ii. 622; Bigelow, *Am. Med. Bot.*, ii. 15. — *Chimaphila corymbosa*, Pursh. *B. & T.* 165. — The pipsissewa is a small evergreen plant, with a perennial, creeping, yellowish root (rhizome), which gives rise to several simple, erect or semiprocrembent stems, from four to eight inches in height, and ligneous at their base. The leaves are wedge-shaped, somewhat lanceolate, serrate, coriaceous, smooth, of a shining, sap-green color on the upper surface, paler beneath, and supported upon short footstalks, in irregular whorls, of which there are usually two on the same stem. The flowers are disposed in a small terminal corymb, and stand upon nodding peduncles. The calyx is small and divided at its border into five teeth or segments. The corolla is composed of five roundish, concave, spreading petals, which are of a white color tinged with red, and exhale an agreeable odor. The stamens are ten, with filaments shorter than the petals, and with large, nodding, bifurcated, purple anthers. The ovary is globular and depressed, supporting a thick and apparently sessile stigma, the style being short and immersed in the ovary. The seeds are numerous, linear, chaffy, and enclosed in a roundish, depressed, five-celled, five-valved capsule, having the persistent calyx at the base. This humble but beautiful evergreen is a native of the northern latitudes of America, Europe, and Asia. It is found in all parts of the United States. It grows under the shade of woods, and prefers a loose sandy soil enriched by decaying leaves. The flowers appear in June and July. All parts of the plant are endowed with active properties. The leaves and stems are found in commerce. The leaves are officially described as "oblanceolate, 2.5 to 5 Cm. long, 8 to 18 Mm. broad, the upper portion coarsely and sharply serrate, acute or somewhat obtuse, the lower wedge-shaped and nearly entire; coriaceous, smooth, and uniformly dark green on the upper surface, paler beneath, the veins being very prominent; odor slight; taste astringent and bitter." *U. S.*

C. maculata (L.), Pursh (*Pyrola maculata*, L.), or *spotted wintergreen*, though not official, probably possesses similar virtues. The character of the leaves of the two plants will serve to distinguish them. Those of *C. maculata* are lanceolate, rounded at the base, where they are broader than near the summit, and of a deep olive green, veined with greenish white; the leaves of the official species are broadest near the summit, gradually narrowing to the base, and of a uniform shining green color.

Properties.—Pipsissewa, when fresh and bruised, exhales a peculiar odor. The leaves have been already described. Their taste is pleasantly bitter, astringent, and sweetish; that of the stems and root unites with these qualities a considerable degree of pungency. Boiling water extracts the active properties of the plant, which are also imparted to alcohol. The leaves have been examined by Samuel Fairbank, who found in them gum, starch, sugar, extractive, pectic acid, tannic acid, resin, fatty matter, chlorophyll, yellow coloring matter, lignin, a peculiar whitish substance which he calls *chimaphilin*, and various inorganic substances, as potassa, lime, magnesia, sodium chloride, and sulphuric, phosphoric, and silicic acids. The chimaphilin was obtained by agitating a tincture with chloroform, allowing the mixture to stand, removing the lighter liquid, and allowing the chloroformic solution to evaporate. A yellow crystalline substance was left, which, purified by solution in alcohol, filtration, and spontaneous evaporation, constituted the substance in question. It was also obtained by simply distilling the stems with water. It is in beautiful, golden-yellow, acicular crystals, inodorous, tasteless, fusible, volatilizable unchanged, insoluble or nearly so in water, soluble in alcohol, ether, chloroform, and the fixed and volatile oils, and possessed of neither acid nor alkaline properties. (*Journ. of the Maryland Coll. of Pharm.*, 1860.)

The active principle of pipsissewa leaves seems to have been isolated by E. S. Beshore (*A. J. P.*, 1887, p. 125) by treatment of the powdered leaves with petroleum spirit. He obtained white crystals, melting at 236° C., sparingly soluble in cold or boiling 90 per cent. alcohol, sparingly soluble in ether, benzin, chloroform, and cold glacial acetic acid; more soluble in hot glacial acetic acid. An ultimate analysis gave the formula $C_{10}H_{12}O$. He also obtained the golden-yellow crystalline principle of Fairbank both from the leaves and the stems. He considers it distinct from the one described above. Josiah C. Peacock (*A. J. P.*, 1892, p. 295) has made a careful analysis of both *C. umbellata* and *C. maculata*. He obtained in several ways the yellow crystalline principle *chimaphilin*, and studied its properties. It forms yellow acicular crystals, nearly odorless and tasteless, insoluble in water, soluble in alcohol, chloroform, ether, benzene, petroleum benzin, acetone, and glacial acetic acid. They may be sublimed by careful heating without change. Chimaphilin melts at 108° to 109° C., and has the composition $C_{24}H_{21}O_4$. Peacock also found three other crystalline principles, for which no formulas, however, are given. Ridenour (*A. J. P.*, 1895, 236) has also prepared chimaphilin, and by the analysis of the purified crystals and of two of its derivatives, confirms the formula, $C_{24}H_{21}O_4$, given by Peacock. He finds the melting point of the purified chimaphilin to be 114° C. He also prepared another crystalline

principle melting above 250° C., to which he gives the formula $C_{10}H_{18}O$, which agrees with Beshore's product. *Arbutin*, $C_{12}H_{18}O_7$, is also found in *chimaphila*.

Uses.—This plant is stated to have been used internally by the North American Indians in *scrofula* and *rheumatism*, and was subsequently a very popular remedy among the settlers of this country. It is now known, however, to be only slightly tonic, astringent, and diuretic. It is one of the mildest, and least effective of the so-called stimulating diuretics, being closely similar to, but less certain and effective than, *uva ursi* in its therapeutic influence and application. The best preparation is the official fluidextract, which may readily be made into a syrup.

Dose, thirty to ninety grains (2 to 6 Gm.).

Off. Prep.—Fluidextractum *Chimaphilæ*, U. S.

CHIRATA. U. S., Br.

CHIRATA

(chī-rā'tā)

"The dried plant of *Swertia Chirayita* (Roxburgh) Hamilton (Fam. *Gentianacæ*)."
U. S. "The dried plant, *Swertia Chirata*, Ham., collected when in flower." Br.

East Indian Balmomy; Chiretta; Chirette, Fr.; Chiretta, Ostindischer Enzian, G.

Swertia Chirayita (Roxb.), Hamilton. *Agathotes Chirayta*, Don, Lond. *Philos. Mag.*, 1836, p. 76.—*Gentiana Chirayta*, Fleming, *Asiat. Research.*, xi. 167.—*Ophelia Chirata*, Grisebach. B. & T. 183.—The *chirayta*, or *chirata*, is an annual plant, about three feet high, with a branching root, and an erect, smooth, round stem, branching into an elegant leafy panicle, and furnished with opposite, embracing, lanceolate, very acute, entire, smooth, three or five-nerved leaves. The flowers are numerous, peduncled, yellow, with a four-cleft calyx having linear acute divisions, the limb of the corolla spreading and four-parted, four stamens, a single style, and a two-lobed stigma. The capsules are shorter than the permanent calyx and corolla. The plant is a native of Nepaul and other parts of Northern India. The whole of it is gathered when the flowers begin to decay.¹

¹ In the Indian bazaars the name *chirata* is applied to various dried gentianaceous plants; the most important of these is the *Ophelia angustifolia*. It yields the *Paharee* or *Hill chirata*, which is distinguished by its inferior bitterness, and its rectangular, winged stems, whose section presents a thick woody ring and a centre nearly or entirely hollow, with only traces of pith. A false *chirata*, which has also found its way into the London markets, and resembles the official variety in having a well developed pith, but which is completely lacking in bitterness, is affirmed to be the product of *Ophelia alata*. (*P. J.*, xvii. 903.) Under the name of Indian *chiratu*, the dried plant of the *Andrographis paniculata*, which is officially recognized by the Pharmacopœia of India, has appeared in the London market. It resembles much more closely recently dried broom tops than the true *chirata*. It is a little more than two feet long. The branching stems are from $\frac{1}{2}$ to $\frac{3}{4}$ inch in

The dried plant is imported into Europe in bundles, consisting mainly of the stems, with portions of the root attached. The stems contain a yellowish pith. The drug is officially described as "smooth; root simple, about 7 Mm. thick near the crown; stem about 1 M. long, externally yellowish or purplish-brown, cylindrical near the base, quadrangular and lightly winged above, with numerous opposite, ascending branches; wood yellowish, thin, enclosing usually a large yellowish easily separable pith; leaves opposite, sessile, ovate-lanceolate, entire, five-nerved, about 6 Cm. long; flowers numerous, panicled, small, with a four-lobed calyx and corolla; capsule ovoid, acute, one-celled, many-seeded; odor slight; taste intensely bitter." U. S. Its fruits are superior, bicarpellary, and unilocular. Its virtues are imparted to water and alcohol, and are retained in the extract. According to Lassaigne and Boissel, the stems contain resin, a yellow bitter substance, brown coloring matter, gum, and various salts. Flückiger and Höhn, who subsequently examined the stems and roots of *chirata*, extracted from them sugar, wax, chlorophyll, soft resin, tannin, an acid which they name *ophelic*, possessing the formula $C_{18}H_{20}O_{10}$, and a peculiar bitter substance, denominated *chiratin*, $C_{28}H_{48}O_{15}$. The acid is syrupy, deliquescent, yellowish brown, at first slightly sour, afterwards intensely bitter. It is soluble in water, with some turbidity, probably owing to resin mixed with it, and completely soluble in alcohol, or a mixture of this with ether. It decomposes certain salts, and forms amorphous compounds with acids. *Chiratin* is a yellow, hygroscopic powder, but feebly crystallizable, very bitter, sparingly soluble in cold water, more so in hot water, and readily dissolved by alcohol and ether. It is neutral to test paper, and yields a copious precipitate with tannic acid. By the action of acids, *chiratin* is separated into *ophelic acid*, and a yellowish-brown, amorphous substance, bitter, scarcely soluble in water, readily soluble in alcohol, and not reducing copper solutions, as the *ophelic acid* does. Höhn gives it the formula $C_{18}H_{24}O_8$, and names it *chiratogenin*. (*P. J.*, Aug. 1870, 106.)

Uses.—*Chirata* has long been used in India. It has been introduced into Europe, and appears to be highly esteemed, but has not been employed to any considerable extent in this country. Its properties are those of the pure bitters, and probably do not differ from those of the other members of the family of *Gentianacæ*. (See *Gentiana*.) Like these, in overdoses it nauseates and oppresses the stomach. Some have supposed that, in addition to its tonic properties, it exerts a peculiar influence over the liver, promoting the secretion of bile

thickness near the base, woody, quadrangular, furrowed, smooth, slightly knotted at the point from which the branches spring, the longitudinal furrows are continued through the roots, which have numerous fine radicles, the leaves are opposite decussate, branches erect or forming an acute angle with the stem, terminal shoots extremely slender.

and correcting it when deranged, and restoring healthy evacuations in cases of habitual costiveness. It has been used in *dyspepsia*, and in the *debility* of convalescence, and generally in cases in which corroborant measures are indicated. In India it has been successfully employed in *intermittents* and *remittents*, combined with the seeds of *Guilandina Bonducella*, L. It may be given in powder, infusion, tincture, or fluidextract.

Dose, twenty grains (1.3 Gm.).

CHLORALFORMAMIDUM. U. S.

CHLORALFORMAMIDE

(chlō'ral-fōr-mā-mī'dūm)

"A crystalline solid [$\text{CCl}_3\text{CH}(\text{OH})\text{NH}\cdot\text{COH}$], made by the direct union of formamide with anhydrous chloral. It should be kept in amber-colored, well-stoppered vials." U. S.

Chloralamide; Chloralum formamidatum, P. G.; Chloralformamid, G.

Preparation.—It is made by mixing 45 Gm. of formamide with 147 Gm. of anhydrous chloral, when combination ensues; the crystalline mass is purified by recrystallization.

Properties.—Chloralformamide¹ is officially described as in "colorless, lustrous crystals, without odor, and having a somewhat bitter taste. Soluble in about 18.7 parts of water, and in 1.3 parts of alcohol at 25° C. (77° F.). It is readily soluble in ether, glycerin, acetone, and acetic ether. When heated with water to 60° C. (140° F.), it is hydrolyzed, hydrated chloral and formamide being produced. When heated to from 114° to 115° C. (237.2° to 239° F.), it melts, but at a higher temperature it is decomposed. It is not affected by diluted acids, but it is decomposed on warming with alkali hydroxides, the solution becoming at first turbid, and then clear, while chloroform separates. If 0.2 Gm. be heated carefully in an open dish, it should not give off inflammable vapors, and should volatilize without leaving a weighable residue (absence of *inorganic impurities* and distinction from *chloral alcoholate* and *ethyl carbamate*). One Gm. of Chloralformamide dissolved in 10 Cc. of alcohol should yield a solution which does not redden moistened blue litmus paper (absence of *formic*, *hydrochloric*, or *other free acids*). If 1 Gm. of Chloralformamide be dissolved in 10 Cc. of alcohol,

the addition of a few drops of silver nitrate T.S. should not at once produce turbidity (absence of *decomposition products*)."² U. S.

Uses.—Locally, chloralformamide is scarcely at all irritant, and when taken internally is quickly absorbed and is eliminated chiefly as urochloralic acid. When given to the lower animals, it produces lethargy, sleep, muscular relaxation, arrested respiration, followed by coma, failing respiration, and, if the dose has been sufficient, death by centric respiratory paralysis. As shown by the experiments of H. C. Wood and Cerna, subsequently confirmed by various observers, its influence upon the circulation and the spinal cord is extremely feeble, and it has no perceptible effect upon the nerve trunks and the muscles. It acts upon the cerebral cortex and therefore as an hypnotic resembles hydrated chloral, but its action is more slowly developed and is less positive. Confusion, giddiness and headache are the only unpleasant effects following its use, and they rarely occur. It is safer than hydrated chloral in the insomnia of cardiac weakness.

Dose, one-half to one drachm (2 to 3.9 Gm.), half an hour before the desired time of sleep.

CHLORALUM HYDRATUM. U. S. (Br.)

HYDRATED CHLORAL

[Chloral, Pharm. 1890, Chloral Hydrate]

(chlō'ral-ūm hŷ-drā'tūm)

"A crystalline solid, composed of trichloraldehyde or chloral [CCl_3COH] with the elements of one molecule of water. It should be kept in glass-stoppered bottles, in a cool and dark place." U. S. "Chloral Hydrate, or trichloroethylidene glycol, $\text{CCl}_3\text{CH}(\text{OH})_2$, is obtained by the addition of water to the liquid chloral produced by the action of dry chlorine gas on ethylic alcohol." Br.

Chloral Hydras, Br.; Trichloraldehyd Hydrate, Trichlorethylidene Glycol; Hydrous Chloral; Chloral Hydraté Fr. Cod.; Hydrate de Chloral, Fr.; Chloralum Hydratum, P. G.; Chloral hydrat, G.; Chloralhydrato, It.; Hidrato de cloral, Sp.

Chloral was so uniformly used as a synonym for Hydrated Chloral that whenever the term chloral was used, the hydrated chloral was intended, and whenever the uncombined substance was referred to, it was designated *anhydrous chloral*. The U. S. P. (8th Rev.) now differentiates the official product by naming it hydrated chloral. Perhaps no medicine ever came so rapidly into extensive use as that now under consideration. Though discovered by Liebig in 1832, it was not until 1869 that its remedial properties were first made known by their discoverer, Otto Liebreich of Berlin; in 1878 the consumption of chloral was estimated at one ton daily in England and America alone; and, although not used now to this extent, it is still largely employed.

¹ *Chloralimide*, $\text{CCl}_3\text{CH}\cdot\text{NH}$, should not be confounded with chloralamide. Chloralimide is in colorless, inodorous, and insipid, long crystalline needles; melting at about 166° C. (330.8° F.); insoluble in water; readily soluble in alcohol, in ether, in chloroform, and in oils. Concerning its physiological action we have no certain knowledge; it is asserted to be hypnotic in doses of from fifteen to sixty grains (1 to 3.9 Gm.).

Anhydrous Chloral.—In preparing anhydrous chloral, the simple method originally employed by Liebig, of acting directly on alcohol by chlorine, is generally preferred, even, we believe, by the larger manufacturers. The following details of the manufacture of hydrated chloral as carried out on a commercial scale have been supplied by E. Schering of Berlin, who has been for years the largest manufacturer of it.

Absolute alcohol, in lots of 50 pounds each, is placed in large glass flasks and saturated with chlorine, which is passed in a continuous stream for 6 to 8 weeks. The chlorine is led into cold alcohol at first, and when no more is absorbed, the alcohol is heated at first gently and then to 60° C. (140° F.). When saturated, the mixture formed, in which the chloral now exists as chloral alcoholate, is agitated with sulphuric acid at a temperature of 60° C. (140° F.) for several hours, during which time most of the hydrochloric acid escapes. The separated chloral is then rectified over calcium carbonate. The pure chloral so obtained is then mixed in glass flasks with the necessary amount of water, and the resulting hydrated chloral either cast into cakes or purified by crystallization. As solvents for this purpose certain of the side products of the chloral manufacture, after being purified and rectified, are used, for instance, ethylene and ethylidene chlorides; or in their absence chloroform is used; petroleum benzin and carbon disulphide have also been recommended. The action of chlorine upon alcohol is said to be aided by the presence of "chlorine carriers," such as iodine, ferric chloride, thallium chloride, etc. The formula of anhydrous chloral is $\text{C}_2\text{H}_3\text{ClO}$; in other words, aldehyde, $\text{C}_2\text{H}_5\text{O}$, in which 3 atoms of hydrogen has been replaced by 3 atoms of chlorine. The name of chloral was derived from the chlorine and alcohol from which it is formed. The anhydrous chloral thus formed is a colorless liquid, of penetrating disagreeable odor, of little taste, of the sp. gr. 1.502, and boiling at 94° C. (201.2° F.). It is soluble in ether or chloroform without change. According to A. Trillat, in the formation of chloral from alcohol, the latter is first changed by the action of the chlorine into aldehyde; this unites with alcohol to form acetal, which is changed successively into mono-, di-, and trichloroacetal; the action of hydrochloric acid decomposes this latter with the formation of chloral alcoholate and ethyl chloride; sulphuric acid decomposes the alcoholate, liberating chloral, which then is made to combine with water to form the crystalline hydrated chloral. (*Bulletin*, 1897, 17, 230.) As the union of hydrated chloral with water develops heat, it is supposed to be more than the formation of a hydrate, and the formula $\text{CCl}_3\text{CH}\cdot\text{OH}$ is assigned to the

resulting compound. It does not show all the reactions of an aldehyde, as, for example,

the red color of a magenta solution that has been decolorized with sulphurous acid, is not restored by it.

Meta-chloral.—By continued contact of anhydrous chloral and concentrated sulphuric acid, a change is effected in the chloral, by which it becomes a solid insoluble in water, which is designated as *insoluble chloral*, or *meta-chloral*. It is tasteless, of a white color resembling porcelain, and insoluble in alcohol and ether. Its formula is $\text{C}_6\text{H}_3\text{Cl}_3\text{O}_3$, being formed by the union of three molecules of chloral. It is stated that when perfectly pure, chloral does not become polymerised; the change is also said to be prevented by the addition of a little chloroform. When heated to 180° C., meta-chloral distils with reversion to liquid chloral. (Allen, *Com. Org. Anal.*, 2d ed., i. p. 171.)

Chloral Alcoholate.—A compound obtained by Roussin, which he announced as pure hydrated chloral, was found by Personne to contain no water, but to be in fact a compound of alcohol and chloral, and is now known by the name of *chloral alcoholate*, $\text{C}_2\text{HCl}_3\text{O}, \text{C}_2\text{H}_5\text{O}$. It results directly from the action of absolute alcohol on anhydrous chloral, and is now known to be formed as a stage in the manufacture of chloral from alcohol. As it is very likely to be confounded with hydrated chloral, the following points of difference should be noted. It forms white crystals melting at 46° C. (114.8° F.), and boils at 113.5° C. (236° F.), while hydrated chloral crystals melt at 58° C. (136.4° F.), and boiling at 97.5° C. (207° F.); chloral alcoholate melts without complete solution when warmed with two volumes of water, and, on cooling, congeals below the surface of the water, while hydrated chloral is soluble in one and one-half times its weight of water; chloral alcoholate, gently heated with nitric acid of 1.2 sp. gr., is violently attacked, while hydrated chloral is scarcely acted on; chloral alcoholate, when heated on platinum foil, inflames readily, while hydrated chloral scarcely burns. (Allen, *Com. Org. Anal.*, 2d ed., i. p. 172.)

The three related products, the *anhydrous chloral*, the polymeric *meta-chloral*, and the *alcoholate*, described above, have been more or less introduced into the European markets, and have required some notice to prevent them from being confounded with the hydrated chloral, which is alone official. The following observations will be confined to this last compound, and the reader will note that whether the simple term chloral, or the exact designation, hydrated chloral, is used, the same substance is intended.

Properties of Hydrated Chloral.—This is made by simply mixing anhydrous chloral with water. Acicular crystals soon form, which result from the union of a molecule each of the chloral and water, constituting hydrated chloral. As employed in the United States, this comes, we believe, exclusively from Europe, and chiefly from Germany. It was at one time

made in this country by E. R. Squibb of Brooklyn. It occurs in commerce mainly in two forms; in distinct crystals, which is the official form, or in crystalline plates, about three lines in thickness, broken into small, irregular pieces, so as to be readily introduced into broad-mouthed bottles. These pieces, while retaining their tabular form, are somewhat translucent, but usually covered with a white powder, which somewhat conceals that property. This is the more common form and the cheaper; but the crystals are to be preferred, as their purity may be relied on. Guerin adds his testimony to the necessity for dispensing only hydrated chloral which has been recrystallized and which is in the form of distinct crystals. He examined many samples, and found acidity in the cake variety, due, as he believes, to the formation of hydrochloric and formic acids, produced by the action of water retained in the cake during the manufacture, and this remaining in contact with the crystals excites decomposition. (*A. Pharm.*, 1886, p. 253.)

Hydrated chloral is white, possessing a peculiar pungent odor, and an acrid pungent taste, especially affecting the velum pendulum. The odor has been compared to that of an over-ripe melon. Exposed to the air it very slowly volatilizes, and, like camphor, when enclosed in a bottle, covers the interior surface with numerous minute crystals. The boiling point of the pure crystals is 97.5° C. (207° F.). If the boiling point be under 95° C., it indicates an under-hydrated preparation; if above 98° C., an over-hydrated one. (E. R. Squibb.) The pure hydrated chloral does not take fire when heated in a spoon, but evaporates without residue. With the aid of heat, its solution may be effected readily in chloroform; and the solution, on cooling, deposits it in beautiful crystals, which are generally needle-shaped, while those deposited from a solution in carbon disulphide are prisms. The aqueous solution is prone to decomposition, which is ultimately attended with the development of low organisms. Hydrated chloral should not, therefore, be kept long in this state. (E. Labbé, *A. G. M.*, Sept. 1870.) In its relation to acids and alkalies it is neutral or, according to E. Schering, slightly acid when perfectly pure. When equal parts of hydrated chloral in crystals and of camphor in small fragments are shaken together in a bottle, and allowed to stand, they liquefy, forming a clear solution. When hydrated chloral and sulphuric acid are mixed, the temperature is greatly reduced. A solution of hydrated chloral dissolves morphine, quinine, and most of the vegetable alkaloids. (R. F. Fairthorne, *A. J. P.*, Oct. 1871, p. 447.) When ammonium sulphide is added to an aqueous solution of hydrated chloral, the mixture rapidly turns yellow, and, after passing through several shades of color, finally becomes dark brown. From this liquid diluted sulphuric acid throws down a bulky brown precipitate. This, purified from precipitated sulphur and dried, is a light-brown

powder of the composition $C_{18}H_{24}Si_3N_4O_6$. Hydrogen sulphide gas forms a sulphhydrate by its action on hydrated chloral. These reactions are important, as the detection of metallic poisons in toxicological cases by hydrogen sulphide has been complicated by the presence of hydrated chloral. A still more important chemical reaction of hydrated chloral is that which takes place when the hydrated, or either of its other forms, is placed under the influence of an alkali. Chloroform is developed, and along with it a formate of the alkali employed. Thus, in a strong solution of potassium hydroxide, put a pinch of powdered hydrated chloral, and almost instantly the odor of chloroform becomes sensible, and some oil-like globules of chloroform may be seen at the bottom of the vessel. The reaction is as follows:

This relation of hydrated chloral to chloroform would serve as a ready test of the former, and may be used also to determine its quality, for pure hydrated chloral ought by calculation to yield 76.35 per cent. of chloroform, and the best known yields, according to the table of Mason, 71.5 (72.20 Selden) per cent. If, therefore, the product of chloroform should fall much below the latter percentage, the parcel acted on is probably impure. For other methods of assaying hydrated chloral see Allen, *Com. Org. Anal.*, i. pp. 174 and 175. The following description and tests are given in the U. S. Pharmacopœia. "Separate, rhomboidal, colorless and transparent crystals, having an aromatic, penetrating, and slightly acrid odor, and a bitterish caustic taste; slowly volatilized when exposed to the air. Freely soluble in water, alcohol, or ether; also in chloroform, benzene, petroleum benzin, carbon disulphide, fixed and volatile oils. It liquefies when triturated with about an equal quantity of camphor, menthol, thymol, or phenol. When dried and heated to about 58° C. (136.4° F.), it melts, forming a liquid having a specific gravity of about 1.575, which, at a higher temperature, should not evolve inflammable vapors. Liquefied Hydrated Chloral solidifies to a crystalline mass between 35° and 50° C. (95° and 122° F.).

Hydrated Chloral is decomposed by caustic alkalies, alkaline earths, and ammonia, chloroform and a formate of the base being produced. When warmed with a few drops of aniline and sodium hydroxide T.S., the intensely disagreeable odor of phenyl-isocyanide (isonitril reaction) should be produced. Hydrated Chloral should be dry, and not readily attract moisture in dry air. A freshly prepared, aqueous solution of Hydrated Chloral should be neutral to litmus paper, but it gradually acquires an acid reaction. A neutral alcoholic solution remains neutral permanently. An aqueous solution of Hydrated Chloral (1 in 20), acidulated with nitric acid, should remain unaffected by silver

nitrate T.S. (absence of *hydrochloric acid* and *chlorides*). If 1 Gm. of Hydrated Chloral be placed in a porcelain dish and be covered with 1 Cc. of nitric acid (sp. gr. 1.38) no yellowish coloration of the mixture should be produced at ordinary temperatures, or even after warming the mixture 3 or 4 minutes, nor should yellowish fumes be produced after ten minutes' warming (absence of *chloral alcoholate*).” *U. S.*

“Soluble in less than its own weight of *water*, *alcohol* (90 per cent.), or *ether*, and in four times its weight of *chloroform*. The aqueous solution is neutral or but slightly acid to *litmus*. On the application of heat Chloral Hydrate fuses to a colorless liquid, which, as it cools, begins to solidify at a temperature of about 120° F. (48.9° C.). In a test-tube it boils, when pieces of broken glass are immersed in it, at from 202° to 206° F. (94.4° to 96.7° C.), and on platinum foil at a slightly higher temperature it volatilizes without residue. In presence of alkaline substances Chloral Hydrate is decomposed and chloroform is liberated. If 4 grammes be heated with 30 cubic centimetres of the *volumetric solution of sodium hydroxide*, no more than 6 cubic centimetres of the *volumetric solution of sulphuric acid* should be required to neutralize the soda which remains free on the completion of the reaction. A solution in *chloroform*, when mixed by agitation with *sulphuric acid*, does not impart color to the acid (absence of certain organic impurities). When 1 gramme of Chloral Hydrate is warmed with 6 cubic centimetres of *water*, and 0.5 cubic centimetre of *solution of potassium hydroxide*, the mixture filtered, sufficient *solution of iodine* added to impart a deep-brown color, and the whole set aside for an hour, a yellow crystalline precipitate of iodoform should not result (absence of chloral alcoholate). Its aqueous solution should not afford any precipitate with *solution of silver nitrate* (absence of free chlorides).” *Br.*

The most delicate test for the presence of chloral alcoholate in hydrated chloral is said to be that with nitric acid. When 1 Cc. of nitric acid (1.38 sp. gr.) is poured over 1 Gm. of hydrated chloral a yellow color should not appear within 10 minutes, even if the mixture be warmed. (*A. J. P.*, 1894, 191.) For other tests for hydrated chloral by Jaworowski, see *Ph. Z. R.*, 1894, 373.

Uses.—When hydrated chloral is ingested in full therapeutic dose (from 15 to 30 grains), it produces in from ten minutes to half an hour a quiet, placid sleep, which usually continues about three hours, when it ceases, generally without any unpleasant symptom during its progress or after its termination. In some instances the ordinary doses fail to cause sleep, and in others the sleep is attended with dreams and hallucinations, and followed by unpleasant symptoms, like those which often succeed other hypnotics, especially opium, such as nausea, headache, unpleasant nervous disorder, etc. These diversities may be ascribed in part to

peculiarity of constitution; but more frequently, in all probability, they are owing to morbid conditions existing at the time, which oppose themselves to the proper action of the chloral. In an individual in health hydrated chloral will probably almost always induce a calm sleep, differing little from the natural. Moreover, these unpleasant symptoms are now much more rarely produced than formerly, and there can be but little doubt that they have often been due to the impurities of the drug. The pulse is in this degree of action not affected, or is rendered a little slower; the pupil is contracted, but becomes normal so soon as the subject is awakened; the respiration is deep, full, and regular. When larger amounts are given, the sleep is much deeper, and may pass into profound coma; the respirations fall in number; the pulse is weakened and rendered slower, but may become rapid and irregular if the dose has been toxic; the temperature is reduced; the muscular system is relaxed, and both sensibility and reflex action are diminished. If a fatal dose has been given, all these symptoms are intensified; with coma, intense muscular relaxation, weak, thready pulse, and a pupil contracted at first, but afterwards dilated, the victim gradually sinks into death, paralyzed and anesthetized. The immediate cause of death is generally a paralytic arrest of respiration, but in many cases there appears to have been a simultaneous arrest of the cardiac action, and it is very possible that fatal syncope may at times occur. At post-mortem examination, congestion of the meninges and substance of the brain and cord, and of the lungs, is commonly found. The blood is thought by Richardson (*M. T. G.*, Sept. 4, 1870) to coagulate less firmly than normal.

After the brain the motor tract of the spinal cord, including the respiratory centre, is most sensitive to the action of hydrated chloral. The loss of voluntary muscular power and the lessening of reflex activity which the drug produces are the result of the spinal influence. Upon the sensory tract of the cord hydrated chloral acts with much less vigor, while the nerves and muscles practically escape its influence. Of course any agent which produces sleep in some measure relieves pain, but the anæsthetic influence of hydrated chloral is far from pronounced, and often patients on waking will complain bitterly of pain suffered during sleep.

The physiological action of hydrated chloral may be summed up as follows. Upon the cerebrum it acts as a most powerful and certain hypnotic; in full doses it acts as an intense depressant upon the centres at the base of the brain, and upon the spinal cord, causing slowing and weakness of the heart's action, probably vasomotor paralysis, slowing of the respiration, and muscular weakness, lessening of reflex activity, with a certain amount of anæsthesia; in fatal doses it causes death generally by arresting respiration through paralysis

of the nerve centres, and finally stopping the heart in diastole. Its action in very small doses is uncertain, but there is considerable evidence to indicate that it irritates or stimulates the spinal and the cardiac, and even the vasomotor, centres. On the vagi and on the motor nerve trunks it has no marked influence. Clinical experience indicates that hydrated chloral acts as a depressant to the heart muscle, although some authorities believe the influence of the drug upon the heart is not direct, but exerted through the nerve-centres. Hydrated chloral has little effect on the secretions, though it is said to somewhat increase the secretion of urine. In man, it is stated by Bouchut that, in accordance with his observations, this secretion is not only increased, but has been found also augmented in density, at the same time reducing Fehling's solution, and rendered brown by potassium hydroxide or bismuth subnitrate, as if a temporary glycosuria were produced. Formic acid has never been found in the urine as a result of the taking of hydrated chloral. (*A. G. M.*, Sept. 1870, p. 346.)

The conversion of hydrated chloral by alkalies in solution into chloroform and formic acid first suggested its use in medicine to Liebreich (*W. M. W.*, August, 1869); and the theory that its action is really due to chloroform generated by the alkalinity of the blood has been received with favor by Personne and other writers, but there are very many facts which militate against the truth of this supposition. Thus, chloroform cannot be detected in either the blood, breath, or excretions of chloralized animals, although chloroform at once manifests itself when it is administered, and in the so-called "salt frogs" of Cohnheim, after substitution of warm salt water for the blood of the animal, hydrated chloral acts as upon the normal batrachian.

Hydrated chloral, especially when used continuously, is said to produce in some individuals serious disturbances. Such are vasomotor paralysis, transient skin neurosis, acute purpura, and great prostration of the heart's action sometimes amounting to paralysis of that organ, and sometimes ending fatally, even though the doses of the chloral used were within the limits ordinarily deemed safe. For a full discussion of these phenomena, see Wood's *Therapeutics*. There can be no doubt that great caution should be practised in administering the drug when the heart is very weak or the general powers are much enfeebled. Jolly relates two cases in which 5 grammes (about 75 grains), given every night, caused death, in one case after the fifth dose, and in the second after the thirteenth dose, without abnormal symptoms until after the last dose, when the action of the heart and respiration suddenly ceased, and the patient died. (*N. Y. M. J.*, Nov. 1872.) These cases would appear to justify the statement that there is a possible cumulative action of the drug. Although 480 grains (31 Gm.) have been recovered from, Fuller has recorded a case in

which a single dose of thirty grains (2 Gm.) proved fatal in a young lady, and two others in which the same quantity caused alarming symptoms in similar circumstances; so that the highest dose to begin with in ordinary diseases, especially in delicate women, should not exceed twenty grains (1.3 Gm.). In poisoning by hydrated chloral, if the case be seen early, the stomach should be thoroughly evacuated by an emetic or the stomach tube, and the system afterwards supported by cardiac and respiratory stimulants, as whisky, ammonium carbonate, etc. Atropine, digitalis, and strychnine should be administered freely, and the same general measures taken to sustain the respiration as are usually practised in opium poisoning. Atropine is undoubtedly of value when there is failure of respiration, and care should always be taken to maintain the bodily temperature by the application of external heat. Artificial respiration should be practised when necessary.

From what has been said it will be readily perceived that the indications for prescribing this remedy are when sleep is to be induced and spasm relaxed. In purely *nervous insomnia*, and in the same affection attendant on various diseases, as in *acute fevers, active congestion of the brain, cerebral inflammation, mania, delirium tremens*, etc., it is superior to opium; fifteen to twenty or twenty-five grains (1 to 1.3 or 1.6 Gm.) are generally sufficient for a commencing dose, to be repeated in half the quantity in an hour if the first dose fails. The sleep is usually calm and undisturbed for three or four hours, and may be renewed, if required, by the repetition of the dose. When the sleeplessness is due to pain, opium is much more effective than hydrated chloral. The combination of hydrated chloral and morphine is often very useful in procuring sleep for the suffering. As an anæsthetic, hydrated chloral should never be employed; the intravenous use of it, as at one time practised in France, is most dangerous and absolutely unjustifiable. In spasmodic affections hydrated chloral is one of the most powerful remedies known. In *tetanus* and in *strychnine poisoning* it is singularly useful, but must be given in very large doses. In *hysteria, severe chorea*, and other functional or spinal convulsions, it is no less efficient. In *epilepsy* and other forms of cerebral convulsions hydrated chloral is of less service, although it is frequently employed with benefit in *puerperal convulsions*. In *local spasms* it is often of service, and it has been used with success in *strangulated hernia, spasm of the glottis, spasmodic croup, asthma, hiccough*, and even in *incontinence of urine*. Hydrated chloral is possessed of very decided antiseptic properties; a solution of the strength of 30 grains to the ounce will preserve animal tissues for a long time. Locally applied, hydrated chloral is stimulating and antiseptic, and may occasionally be used with very good results in the treatment

of *foul sores, irritable ulcers, etc.*, which need stimulation. The solution may vary from five to thirty-one grains to the ounce, according to the exigencies of the case. A. M. Fauntleroy states that if powdered hydrated chloral be sprinkled on adhesive plaster and the whole heated sufficiently to adhere to the skin, and applied while warm, there is produced an increasing burning, and in about ten minutes a blister is formed.

Hydrated chloral is best administered in solution with syrup of orange flowers, or in simple solution. The French sometimes employ *chloral cream*, made of hydrated chloral 5 parts, water 15 parts, white sugar finely powdered 100 parts, flavored with mint, orange, or vanilla. One grain of hydrated chloral is contained in 24 grains of the cream, and a teaspoonful is equivalent to about 3 grains of hydrated chloral. This preparation keeps well, and the dose may be dissolved in a little water. *Chloral liniment* may be made by dissolving 6 parts hydrated chloral in 30 parts oil of sweet almonds. *Chloral ointment*, 6 parts hydrated chloral, 3 parts white wax, 27 parts lard; the lard and wax are melted at a gentle heat, the hydrated chloral added in powder and dissolved. *Chloral plaster*, to produce counter-irritant effects, is prepared by spreading powdered hydrated chloral on Burgundy pitch plaster; care should be taken to distribute it uniformly.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

CHLOROFORMUM. U. S., Br.

CHLOROFORM

(ghlō-rō-fōr'mūm)

$\text{CHCl}_3 = 118.45$

"A liquid consisting of 99 to 99.4 percent., by weight, of absolute Chloroform [$\text{CHCl}_3 = 118.45$], and 0.6 to 1 percent. of alcohol. It should be kept in dark amber-colored, glass-stoppered bottles, in a cool and dark place." U. S. "Chloroform, or trichloromethane, CHCl_3 , to which has been added sufficient Absolute Alcohol to produce a liquid having a specific gravity not less than 1.490, and not more than 1.495. Trichloromethane may be prepared by heating a mixture of chlorinated lime, slaked lime, ethylic alcohol, and distilled water." Br.

Trichloromethane, Methenyl Trichloride; Chloroformum Purificatum, U. S. 1880; Formylum Trichloratum; Chloroforme Officinal, Fr. Cod.; Chloroformium, P. G.; Reines Chloroform, Chloroform, G.; Chloroformio, It.; Chlorido formico, Chloroformo, Sp.

Neither the U. S. nor British Pharmacopœias give detailed processes for chloroform. (See U. S. D., 17th ed., 370.)

In the U. S. Pharmacopœia of 1850 a process was given for preparing chloroform; but, as this is never made on a small scale by the apothecary, it was very properly transferred, in 1860, to the *Materia Medica Catalogue*.

Chloroformum venale, or commercial chloroform, was introduced, and also a formula for the purification of chloroform; this was very properly dropped in the U. S. P. 1890, as pure chloroform is now furnished by the manufacturers and easily obtainable at a moderate price; the process for purifying chloroform attached to the tests of the U. S. P. (1880) will be found below. The process of the British Pharmacopœia (1885) is for the preparation of the chloroform *ab initio*, with directions which secure its purity if complied with. In this process, the reaction by which the chloroform is produced takes place between the chlorinated lime and the alcohol, the slaked lime being intended probably to lessen the production of the chlorinated pyrogenous oil. As first distilled, the chloroform is very impure, and is directed to be washed first with ordinary water, and afterwards with distilled water, which separate alcohol, chlorine, and probably other contaminating substances. In consequence of the density of the chloroform and its insolubility in water, it readily subsides, forming a distinct layer which may be easily separated. The crude product, after having been freed from alcohol by the washing with water, is purified from the chlorinated pyrogenous oil, which comes over with the chloroform, by agitation with an equal volume of sulphuric acid, which ought to be pure and colorless, and at least of the density of 1.840. The oil is charred and destroyed by the acid, which becomes yellow or reddish brown, and is partially changed into sulphurous acid. To remove the latter acid, as well as any water present, the chloroform, which floats on the surface of the acid, is removed and agitated well with chloride of calcium and quicklime, then again submitted to distillation, and one per cent. of absolute alcohol added to preserve the chloroform from decomposition. In the U. S. 1880 process (see 16th edition U. S. D.) the method of purification is somewhat different. Instead of equal measures of the impure chloroform and sulphuric acid and an agitation for only 5 minutes, the commercial chloroform is shaken occasionally for 24 hours with but one-fifth of its weight of the acid. To remove any water and acid that may be present, instead of calcium chloride and lime, a little stronger alcohol is mixed with the chloroform in a dry retort, and then lime in coarse powder is added, and the mixture is distilled to dryness.

Purification. U. S. P. 1890.—Chloroform which fails to respond to the official tests (see p. 331) should be purified by the following process. "Chloroform, *four hundred grammes* [or 14 ounces av., 48 grains]; Sulphuric Acid, *eighty grammes* [or 2 ounces av., 359 grains]; Dried Sodium Carbonate, *twenty grammes* [or 308 grains]; Deodorized Alcohol, *four cubic centimeters* [or 65 minims]. Add the Sulphuric Acid to the Chloroform, contained in a glass-stoppered bottle, and shake them together occasionally during twenty-four hours, avoiding

exposure to bright daylight. Separate the lighter Chloroform layer, add to it the Dried Sodium Carbonate, previously rendered anhydrous by heating it in a porcelain capsule on a sand-bath until it ceases to give off aqueous vapor, and shake them together frequently and thoroughly during half an hour. Then transfer the Chloroform to a dry retort, add to it the Alcohol, and distil, by means of a water-bath, at a temperature not exceeding 67.2° C. (153° F.), into a well-cooled receiver, until the distillate measures *two hundred and fifty-five cubic centimeters* [or 8 fluidounces, 298 minims].” U. S. 1890.

It sometimes happens that the chloroform purified with sulphuric acid, though apparently pure at first, will not keep, but after some time becomes so loaded with chlorine and hydrochloric acid as to be altogether unfit for respiration. Squibb attributed the fact that chloroform purified by concentrated sulphuric acid does not keep well, to the very purity attained. He believed that perfectly pure chloroform is prone to decomposition, and is rendered more stable by the addition of a small proportion of alcohol, so as to reduce its density to the official standard. This he effected by adding alcohol in the proportion of ten drops to each fluidounce of good chloroform of maximum density (see *Amer. Med. Monthly*, July, 1857). This recommendation was carried into effect in the U. S. 1880 process, and explains the addition of alcohol before distillation. Gregory also attributes the tendency to decomposition to its purity, and to the action of sunlight; having found that those portions which he had purified with the greatest care were soonest decomposed under the influence of light. For methods of preserving chloroform by the use of sulphur, hypophosphorous acid, etc., see *P. J.*, 1895, 261; also 1896, 249.

As chloroform of great purity is *usually* to be purchased in the market, it is not necessary for the pharmacist to apply the official process of purification to every parcel that he may meet, but it is in the highest degree incumbent on him to stand the tests given in the Pharmacopœia, and if he can obtain none so pure, then to purify it himself.

The intermediate formation of hydrated chloral as a result of the reaction between alcohol and chlorinated lime suggested the preparation of chloroform from hydrated chloral. The advantages which were anticipated from decomposing pure hydrated chloral with alkalis have not altogether been realized, for the product is much more expensive, and the claim of greater stability has not been sustained, as it requires just as much alcohol to preserve it as that made in the usual way.

Chloroform is now made on a large scale both in this country and in Germany by the distillation of acetone with chlorinated lime; indeed, this process has entirely replaced the manufacture from alcohol. Liebig, as long ago

as 1832, described the reaction, but it was thought to be not adapted for commercial use. In 1882 the manufacture was begun on a commercial scale at Mannheim, Germany, and since June, 1885, in this country. To get a satisfactory yield a very pure acetone is necessary. When such acetone is taken, a yield of nearly or quite 200 per cent. of chloroform can be obtained. (For an account of the methods of purifying the acetone and distilling with chlorinated lime, see *A. J. P.*, 1889, p. 321.) In July, 1885, a patent was taken out by G. Michaelis of Albany, for the manufacture of chloroform from the liquid products resulting from the decomposition of crude acetates at high temperatures. These liquid products are acetone and other higher ketones. The purified chloroform from acetone has a small quantity of alcohol added to prevent decomposition and bring it to pharmacopœial requirements. Pure methyl alcohol, on the other hand, does not yield chloroform. The erroneous statements on this point generally current are probably due to the fact that commercial wood spirit contains a large percentage of acetone.

E. R. Squibb preferred acetic acid to the acetates in the intermediate step of making acetone, thus avoiding impurities likely to be present in acetates; he believed that the grant of a patent for “acetone chloroform” was deficient in equity. (*Ephem.*, 1896, 1743 to 1757.)

Still another method for the manufacture of chloroform from acetone is described in the French technical journals,—viz., to electrolyze a solution of common salt mixed with acetone. A retort of enamel-lined iron, jacketed at the bottom so as to be heated by steam, and provided with a delivery and condensing tube, is used. A 20 per cent. solution of common salt is introduced into the retort and heated to boiling, when the current is made to pass and a continuous stream of acetone is run in. The nascent chlorine liberated rapidly converts the acetone into chloroform, and it distils over. It is claimed that “190” per cent. of the weight of the acetone taken is obtained as chloroform. Lead electrodes were used at first, but these have been replaced by carbon rods which can be attached to a vertical shaft and made to serve as stirrers. The negative electrode consists of a copper cylinder. (*Revue Scientifique*, Feb. 1893.)

Carbon tetrachloride (CCl_4) has also been proposed (1896) as a source of chloroform, and as it is now made cheaply on a large scale, it may come into use. By the action of hydrochloric acid and zinc, hydrogen is liberated and attacks the carbon tetrachloride, forming chloroform and hydrochloric acid,

As hydrochloric acid is a product of the reaction, fresh quantities of zinc are attacked, and a new liberation of chloroform follows.

Discovery and History.—Chloroform was discovered by Samuel Guthrie of Sackett’s Harbor, N. Y., in 1831, and about the same time by

Soubiran in France, and Liebig in Germany. Guthrie obtained it by distilling a gallon from a mixture of three pounds of chlorinated lime and two gallons of alcohol of the sp. gr. 0.844, and rectifying the product by redistillation, first from a great excess of chlorinated lime, and afterwards from potassium carbonate. (*Silliman's Journal*, vol. xxi., Jan. 1832, p. 64.) In a subsequent letter to Silliman, dated Feb. 15, 1832, Guthrie states that the substance which he had obtained, "distilled off sulphuric acid, has the specific gravity of 1.436, or a little greater; and may then be regarded as free from alcohol; and if a little sulphuric acid which sometimes contaminates it be removed by washing it with a strong solution of potassium carbonate, it may then be regarded as *absolutely pure*." (*Ibid.*, vol. xxii., July, 1832, p. 105.) It is thus evident that Guthrie obtained, in a pure state, the substance now called chloroform; but he erroneously supposed his product to be the well known oily liquid of the Dutch chemists, which it greatly resembles, and for the preparation of which he believed he had fallen on a cheap and easy process. Under this impression, he called the substance, in his communications, *chloric ether*, one of the names by which *Dutch liquid*, or *ethene dichloride*, is designated. He was induced to make the preparation from noticing in Silliman's *Elements of Chemistry* a reference to the Dutch liquid as a grateful diffusible stimulant when properly diluted with alcohol and water. (See also *West. Drug.*, 1894, 51.)

Properties.—Chloroform is "a heavy, clear, colorless, mobile and diffusible liquid, of a characteristic, ethereal odor, and a burning, sweet taste. Specific gravity: not below 1.476 at 25° C. (77° F.). Chloroform is volatile even at a low temperature, and boils at 60° to 61° C. (140° to 141.8° F.). It is not inflammable, but its heated vapor burns with a green flame." *U. S.* "A liquid of characteristic odor and pungent sweet taste. Specific gravity 1.490 to 1.495. It should boil between 140° and 143.6° F. (60° and 62° C.)." *Br.* According to Remys (*A. Pharm.*, 3, v. 31), pure chloroform has the sp. gr. of 1.500 at 15° C. (59° F.). Besnou gives the densities of various mixtures of alcohol and the purest commercial chloroform at 4.5° C. (40° F.) as follows:

Specific Gravity.	Chloroform, per cent.	Alcohol, per cent.	Specific gravity.	Chloroform, per cent.	Alcohol, per cent.
1.4945	100.0	0.0	1.4772	97.5	2.5
1.4908	99.5	0.5	1.4602	95.0	5.0
1.4874	99.0	1.0	1.4262	90.0	10.0
1.4840	98.5	1.5	1.4090	87.5	12.5

When pure, it has no action on potassium, except to cover the surface of the metal with small bubbles of gas. Chloroform is a powerful antiseptic. Like creosote, it does not coagulate albumin. It is scarcely acted on by sul-

phuric acid in the cold, but dissolves readily in alcohol and ether. The alcoholic solution, when moderately diluted with water, forms an aromatic, saccharine liquid of a very grateful taste. A strong alcoholic solution is decomposed by abundance of water, the chloroform separating and subsiding, and the alcohol uniting with the water. "Soluble in about 200 times its volume of cold water, and, in all proportions, in alcohol, ether, benzene, petroleum benzin, and the fixed and volatile oils." *U. S.* It is liable to decomposition by sunlight, or even diffused daylight; and hence the propriety of keeping it in bottles covered with dark paper, in a rather dark place. Chloroform has extensive solvent powers, being capable of dissolving caoutchouc, gutta-percha, mastic, elemi, tolu, benzoin, and copal. Amber, sandarac, lac, and wax are only partially soluble. It also dissolves iodine, bromine, the organic alkalies, the fixed and volatile oils, most resins, and fats. It dissolves sulphur and phosphorus sparingly.

It possesses the power of dissolving a large quantity of camphor, and furnishes the means of administering that medicine in an elegant form. As a general solvent, it has the advantage over ether of not being inflammable, the inflammability of the latter being the cause of frequent accidents. For an extensive list of substances soluble, insoluble, and partly soluble in chloroform, see a paper by Lepage of Gisors, France, copied into *A. J. P.*, 1852, p. 147. It has been found by J. B. Barnes that chloroform has the power of preventing the alcoholic, lactic, and other fermentations, probably by killing the organisms that provoke these processes. Twenty minims preserved sixteen ounces of malt, to which two drachms of yeast had been added, as long as the experiment lasted. The same quantity kept fresh eight fluidounces of milk in a warm place for five days. Mucilage and infusions were preserved for weeks with one minim or even less to the ounce. Similar results were reached by F. J. Barrett and others. (*P. J.*, 1874, pp. 441, 442, 455.) The active properties of chloroform forbid its use as a preservative of medicinal infusions, but from milk it could always be removed by boiling. A. Munz (*P. J.*, 1875, p. 967) proposes the employment of chloroform as a test between chemical and living ferments, since he has found

it to have no effect upon the former, though absolutely destructive to the latter.

Composition.—Chloroform is composed of one atom of carbon, one of hydrogen, and three of chlorine. Its simplest derivation in

theory is from marsh-gas (*methane*), CH_4 , whence it is often called *trichloro-methane*. While it can be thus produced, by the action of chlorine upon marsh-gas, in practice, it is formed either from alcohol by the action of bleaching powder, from chloral by an alkaline hydroxide, or latterly from acetone and bleaching powder.

The reactions are sometimes complex, but if the temperature be carefully kept at from 70°C . (158°F .) to 73°C . (163.4°F .), they are essentially as follows:

$\text{C}_2\text{H}_5\text{O} + \text{CaOCl}_2 = \text{CaCl}_2 + \text{C}_2\text{H}_4\text{O} + \text{H}_2\text{O}$
that is, one molecule of bleaching powder, reacting with one of alcohol, yields one of calcium chloride, one of aldehyde, and one of water. The aldehyde formed is then further decomposed, according to the reaction:

that is, two molecules of aldehyde, reacting with six of bleaching powder; yield three of calcium chloride, three of calcium hydroxide, and two of chloral. The chloral is, however, decomposed by the free base calcium hydroxide, according to the reaction:

that is, two molecules of chloral reacting with one of calcium hydroxide yield one of calcium formate and two of chloroform. The reaction for the manufacture from acetone is simpler:

Tests.—Chloroform is liable to contain alcohol and ether, both of which lower its specific gravity. If it have a less density than 1.38, it will float instead of sinking in a mixture of equal weights of concentrated sulphuric acid and water after it has cooled. M. Mialhe has proposed the following tests for the presence of alcohol. Drop into distilled water a small quantity of the chloroform. If pure, it will remain transparent at the bottom of the glass; but if it contain even a small proportion of alcohol, the globules will acquire a milky appearance. Soubeiran's method was to agitate almond oil and chloroform together in a tube. If the chloroform is pure, it remains clear; if it contains as much as 5 or 6 per cent. of alcohol, it becomes milky. (*J. P. C.*, Août, 1860, p. 95.) Procter detected alcohol by adding the suspected chloroform to an oxidizing mixture of potassium dichromate and sulphuric acid. If alcohol be present, the deep orange color of the chromic mixture will gradually become green; if absent, no change of color will take place. (*A. J. P.*, 1856, p. 213.) Hoffmann's violet has been suggested as a test. If a small portion is added to chloroform containing alcohol, the solution is colored a deep purple. Boettger recommends adding to the chloroform a solution of molybdic acid in pure, strong sulphuric acid, when even a trace of alcohol will cause an intense blue color. (1879.) Chloroform, when pure, upon being

mixed with an equal volume of sulphuric acid, does not color it; but when contaminated with pyrogenous oils it gives the acid a color varying from yellow to reddish-brown, according to the amount of impurity. Alcohol also is detected and removed by sulphuric acid. In applying this test, several fluidounces of chloroform should be used, as a slight change of color cannot be easily seen in a test tube, and care must be taken to see that mechanical impurities, like cork dust, dirt, etc., have been filtered out of the specimen, or the acid will be discolored from this cause. A still more delicate test of the oily impurities, according to Gregory, is the odor which they leave. If chloroform thus contaminated be poured upon the hand, it quickly evaporates, leaving the oily impurities, recognizable by their offensive odor, now no longer covered by that of the chloroform. The pure substance, rubbed on the skin, quickly evaporates, and leaves scarcely any odor. Chloroform sometimes contains Dutch liquid, which may be discovered by adding an alcoholic solution of potassium hydroxide, when the mixture, if this impurity be present, will heat and give off a permanent gas, which is *acetyl chloride*, $\text{C}_2\text{H}_3\text{OCl}$. (Geuther.) Fuming nitric acid, heated with chloroform to 100°C . (212°F .) in a closed tube for 120 hours, forms a new substance, *chloropicrine*.

Two methods for purifying chloroform, one physical and the other chemical, have attracted much attention. The first of these is the Pictet method of purifying the chloroform by submitting it to very low temperatures, whereby the impurities are first frozen out and filtered off from the chloroform at -70°C ., and then the chloroform itself is solidified at from -80°C . to -100°C . and separated from any liquid impurities. It was at first claimed for this "Chloroform Pictet" that it would not be decomposed by sunlight and did not require the addition of alcohol to preserve it. These claims do not seem to be substantiated by later tests. The other method is based on the discovery of R. Anschütz, that chloroform crystallizes out with salicylid, $\text{C}_6\text{H}_4 \begin{Bmatrix} \text{CO} \\ \text{O} \end{Bmatrix}$, and *o*-homosalicylid,

$\text{C}_6\text{H}_3(\text{CH}_3) \begin{Bmatrix} \text{CO} \\ \text{O} \end{Bmatrix}$, while the impurities of chloroform remain. These crystalline compounds contain respectively 33.24 and 30.80 per cent. of chloroform, and this can be liberated from its combination by very moderate heating. The compounds can be kept for a long time in closed vessels in a slight atmosphere of chloroform, and the salicylid and *o*-homosalicylid can be used over and over again. After becoming acid, through exposure to light, chloroform may be readily regenerated, by agitating it with solution of sodium carbonate, and distilling from a little unslaked lime. From what has been said above, chloroform to be kept for use should have the sp. gr. 1.476, and if denser than this, should be brought

to it by the addition of alcohol. It is best kept in cork stoppered bottles. As the cork is not acted on by chloroform, if it become yellow and softened it will indicate the presence of an acid, and thus act as a test. (*A. J. P.*, 1868, p. 289.)

"If 10 Cc. of Chloroform be poured upon a piece of clean, odorless filter paper laid flat upon a warm glass plate, and the plate be rocked from side to side until the liquid is all evaporated, no foreign odor should become perceptible as the last portions disappear from the paper, and the paper should be left odorless. If 10 Cc. of Chloroform be well shaken with 20 Cc. of distilled water, and the liquid be allowed to separate completely, the water should be neutral to litmus paper, and should not be affected by silver nitrate T.S. (absence of *chlorides*), nor colored by potassium iodide T.S. (absence of *free chlorine*). If 40 Cc. of chloroform be shaken with 4 Cc. of colorless, concentrated sulphuric acid in a 50 Cc. glass-stoppered cylinder during twenty minutes, and the liquids be then allowed to separate completely, so that both are transparent, the chloroform should remain colorless, and the acid should appear colorless, or very nearly colorless, when seen in a stratum of not less than 15 Mm. in thickness (absence of *impurities decomposable by sulphuric acid*). If 2 Cc. of the sulphuric acid, separated from the Chloroform, be diluted with 5 Cc. of distilled water, the liquid should be colorless and clear, and, while hot from the mixing, should be odorless, or give but a faint vinous or ethereal odor (absence of *odorous decomposition products*). When further diluted with 10 Cc. of distilled water, it should remain clear, and should not be affected by silver nitrate T.S. (absence of *chlorinated decomposition compounds*)."*U. S.* "On allowing 20 cubic centimetres to evaporate from a large piece of filter-paper placed on a warm plate, no foreign odor is perceptible at any stage of the evaporation. Water which has been shaken for five minutes with half its volume of Chloroform, and separated from the Chloroform, should be neutral to litmus (absence of acid), should not afford any color with 1 cubic centimetre of *solution of cadmium iodide* and two drops of *mucilage of starch* (absence of free chlorine), and should not yield more than a very slight opalescence with four drops of *solution of silver nitrate* (absence of chlorides). After shaking sulphuric acid with ten times its volume of Chloroform for twenty minutes, and setting aside for fifteen minutes, both the acid and the Chloroform should be perfectly transparent and nearly colorless. 2 cubic centimetres taken from the layer of *sulphuric acid*, and diluted with 5 cubic centimetres of *water*, should remain transparent and very nearly colorless, and should have a pleasant odor. When this liquid is further diluted with 10 cubic centimetres of *water*, and stirred with a glass rod, it should still be transparent and colorless, and the addition of four

drops of *solution of silver nitrate* should not cause more than a slightly diminished transparency. Water which has been shaken with half its volume of Chloroform, previously treated with *sulphuric acid* as described above, should not afford more than a slightly diminished transparency with *solution of silver nitrate*. (The foregoing four tests indicate absence from the Chloroform of products of its decomposition.) It evaporates without residue (absence of fixed matter)." *Br.* These tests imply the presence of but a minute proportion of alcohol, and the total absence of chlorine and those volatile and empyreumatic substances which constitute the most injurious impurities of chloroform. A heat that would be felt through the bottle, on the admixture of sulphuric acid with chloroform would evince the presence of too much alcohol or water. The want of discoloration from the contact of the two liquids shows the absence of empyreumatic oily matter. A color bordering on that of sherry wine would imply an objectionable amount of impurities. The volatile impurities are less volatile than chloroform, and would consequently be the last to escape on the evaporation of the liquid. Impure Chloroform, therefore, leaves a foreign odor behind it when allowed to evaporate from the hand, and especially when from a porcelain plate, in the amount and manner indicated; and if a specimen stand this test well, it may be considered as free from noxious volatile impurity. The slight foreign aroma without pungency, which is given out under these circumstances, is of no injurious significance. It is stated that chloroform made from chloral may be distinguished from other chloroform by its remaining colorless when the sulphuric acid test is employed, and by its leaving no aromatic residue when evaporated, evidences of its absolute purity. It has been claimed that this chloral chloroform does not undergo decomposition, but this has been proved not to be correct. (*A. J. P.*, xlii. 409.)

Uses.—Chloroform, when applied locally, is very irritant and produces decided pain, which may be followed by some numbness and local anæsthesia. If the chloroform be prevented from evaporating, its prolonged contact with the skin is apt to produce blistering. Taken internally, it is absorbed and acts upon the general system. The rapidity of its absorption, and, to some extent, its general effects, depend upon the method in which it is administered. It is commonly exhibited by the mouth or by inhalation. Taken into the stomach in doses of about five minims (0.3 Cc.), it induces only gastric symptoms, chiefly due to its irritant properties; but when there is excessive flatulence, colic, or gastralgia, it not only causes an increased peristalsis and expulsion of any flatus present, but evinces a distinct local narcotic influence by quieting pain and spasm. Taken in doses of 1 to 2 fluidrachms (3.75 to 7.5 Cc.), it produces a narcotism similar to that seen when it is administered by inhalation, the nar-

cotism, however, developing and passing off much more slowly than in the latter case. Chloroform was used internally in *asthma* and other conditions as early as 1832 by Ives of New Haven (*Silliman's Journ.*, xxi, 406, 407), and subsequently in various conditions by several European physicians. In January, 1832, it was employed by Ives by inhalation (*Silliman's Journ.*, vol. xxi, 406), but it was not until November, 1847, that Simpson of Edinburgh brought it forward as more agreeable, efficacious, and convenient in general anæsthesia than ether. The subject of the use of chloroform as an anæsthetic is so important that to be of practical service more space would be required for its discussion than can be afforded in a work like the present, and it need only be said that it is generally considered more convenient but more dangerous than ether. For a full discussion of the subject, therefore, the reader is referred to *Wood's Therapeutics* or to special treatises on anæsthetics.

Locally, chloroform is employed as a very prompt, active counter-irritant and narcotic in *neuralgia*, *colic*, etc., and deep injections of it in the neighborhood of painful nerve trunks have been practised by Roberts Bartholow with asserted good effects. Fournié has found that the vapor from a mixture of equal measures of glacial acetic acid and chloroform is even more effectual, as a local anæsthetic, than that of pure chloroform, producing complete insensibility of the skin in five minutes, if applied from a bottle heated simply by the hand. (*P. J.*, 1862, p. 385.) Chloroform, in vapor, may be used as a topical application to the rectum. Ehrenreich employed it with success in *tenesmus*. A drachm may be vaporized by the heat of warm water, from a bottle, fitted with a flexible tube, inserted into the bowel. Langenbeck of Berlin, prefers chloroform to tincture of iodine as an injection for the radical cure of *hydrocele*. *Chloroform ointment* is made by adding twenty parts of chloroform to a mixture of ten parts of white wax and ninety parts of lard, previously melted together, and allowing the whole to cool.

Chloroform may be gelatinized by agitating it with an equal weight of white of egg in the cold. In three hours it takes the gelatinous form. A stronger preparation may be made by shaking together, in a bottle, four parts of chloroform and one of white of egg, and placing the mixture in water at 60° C. (140° F.). In four minutes the gelatinization is completed. *Gelatinized chloroform* may be applied to the skin, spread on linen, or by friction. *Syrup of chloroform* may be made by adding one fluid-ounce of spirit of chloroform to fifteen fluid-ounces of syrup.

When an overdose of chloroform is taken by the mouth, it is essential to empty the stomach by the pump or siphon tube, and then treat the case much as in serious narcosis, from inhalation. In a case of suicide by swallowing chloroform, in which death took place in about thirty-

four hours, the lining membrane of the larynx and trachea was found inflamed, the bronchi were loaded with a dirty-gray purulent fluid, the lungs were inflamed as in the first stage of pneumonia, and the brain and its membranes congested; but these morbid appearances are not constant.

In relation to the preparations, consisting of chloroform and alcohol, which have been used under the name of "chloric ether," the reader is referred to *Spiritus Chloroformi*.¹

Dose, of chloroform, five to fifteen minims (0.3 to 0.9 Cc.).

CHONDRUS. U. S.

CHONDRUS [Irish Moss]

(zhōn'drus)

"The dried plant of *Chondrus crispus* (Linné) Lyngbye (Fam. Gigartinaceæ)." *U. S.*

Carrageen, Caragahen, Fucus Crispus, Pigwrack, Killeen, Pearl Moss; Carragheen; Carragaheen; Carrageen ou Mousse perlée, *Fr. Cod.*; Mousse Marine perlée, *Fr.*; Carrageen, *P. G.*; Irlandsches Moos, *Perlmoos*, Knorpeltang, *G.*; Fuco carageo, Musco d'Irlanda, Fuco crispo, *It.*; Caragaen, Musgo marino perlado, *Sp.*

Chondrus crispus, Greville, *Alg. Brit.* 129, t. 15; *B. & T.* 305.—*Sphaerococcus crispus*, Agardh.—*Fucus crispus*, Linn.—The Irish moss, or carrageen as it is frequently called, consists of a flat, slender, cartilaginous frond, from two to twelve inches in length, dilated as it ascends until it becomes two or three lines in width, then repeatedly and dichotomously divided, with linear wedge-shaped segments, and more or less curled up so as to diminish the apparent length. The capsules are somewhat hemispherical, and are embedded in the disk of the frond. The plant grows upon rocks and stones on the coast of Europe, and is especially abundant on the southern and western coasts of Ireland, where it is collected. It is also a native of the United States, and is said to be gathered largely on the southern sea coast of Massachusetts, where it is partly torn from the rocks and partly collected upon the beach, on

¹ *Chlorodyne*.—An empirical remedy under this name was first used in London, but is now in some of its imitations very largely employed in various parts of the world. Many formulas are extant. The following has been extensively used in Philadelphia. Morphine hydrochloride 8 grains, water, hydrochloric acid, each 30 minims, chloroform 90 minims, tincture of cannabis indica 1 fluidrachm, hydrocyanic acid, *U. S.* P. 12 minims, alcohol half a fluidounce, oil of peppermint 2 minims, oleoresin of capsicum 1 minim. The morphine hydrochloride and water are heated in a flask with the hydrochloric acid until a clear solution is produced, then the other ingredients are mixed together, and when the first solution is cold the mixture added to it. This is a dangerous remedy, and should be used with great care in three- to ten-drop doses for an adult. (See *Tinctura Chloroformi et Morphine Composita*.)

which it is thrown up during storms. It is prepared for market by spreading it out high on the beach, to dry and bleach in the sun. (Aug. P. Melzar, *Proc. A. Ph. A.*, 1860.) For elaborate accounts of the plant, of its distribution on the sea coast of Massachusetts, and of the mode of gathering and curing, see *U. S. Agricultural Report*, 1866; also *A. J. P.*, 1868, 417; 1895, 596; 1899, 483. Henry Kraemer witnessed the methods pursued on the Massachusetts coast in the collection of Irish moss at Scituate, which appears to be a particularly favorable situation. The season for collection begins late in May and continues to September, June and July being the best months. The moss at present is only found on rocks that are from 15 to 20 feet below the tide, hence women no longer engage in its collection. The men go out in their sail boats or dories at half tide, and come in at half flood. With their long rakes they scrape the moss off the rocks, collecting thus about 50 pounds to the boat, the total for the season at Scituate being about 10,000 pounds. The moss is spread out on the high beach for a week or so, the action of the sun and dew bleaching it. It is then enclosed in hogsheads, in which it is again saturated with sea water by rolling them in the marshes; after which it is again spread out and subjected to the bleaching process, this alternate treatment being repeated four or five times, until the product is of a yellowish or white color. The final drying is done in barns, where the moss is stored until it is packed in 100 lb. barrels at the end of the season. In the course of his journey he had opportunity to observe the *Chondrus* growing and gathered in different localities along the coast, and found it to consist chiefly, if not entirely, of *Chondrus crispus*. While it is stated in Dr. Farlin's "The Marine Algae of New England" that the closely resembling *Gigartina mamillosa* is common from Boston northward, Kraemer is inclined to believe that *Chondrus crispus* (L.), Lyngbye, is practically the only source of the American drug. (See *Proc. Penn. Pharm. Assoc.*, 1899, 113-116.)

Gigartina mamillosa, Ag., *Phycologia Britannica*, Pl. 199, resembles the true Irish moss, and, growing with it upon the rocks, is often gathered with it. It can, however, be at once distinguished by the numerous papillæ which cover the surface and margins of the fronds and bear the fruit (cystocarps). In chemical and medicinal properties it is probably identical with *C. crispus*.

Irish moss when collected is washed and dried. It is probably sometimes bleached by the use of potassium permanganate and sodium thiosulphate by the same process as that used for bleaching sponge. Herr Schack was led to suspect this through discovering the presence of sulphurous acid in a German specimen. (*Ph. Ztg.*, 1886, p. 87.) In the fresh state it is of a purplish color, but, as found in the shops, is yellowish or yellowish white, with occasionally

purplish portions. It is officially described as "usually in light yellow or yellowish-white matted masses; the plant consisting of a slender, somewhat flattened base about one-half the length of the entire frond, which after repeated forking terminates in a number of palmately branching, somewhat enlarged, commonly emarginate or two-lobed segments; translucent, sometimes with fruit bodies embedded near the apex of the segments; somewhat cartilaginous; having a slight sea-weed odor, and a mucilaginous somewhat saline taste. One part of *Chondrus* boiled for ten minutes with 30 parts of water yields a solution which gelatinizes on cooling, and is not colored blue by iodine T.S." *U. S.* It swells in cold water, but does not dissolve. Boiling water dissolves a large proportion of it, and the solution, if sufficiently concentrated, gelatinizes on cooling. Herberger found 79.1 per cent. of pectin, and 9.5 of mucus, with fatty matter, free acids, chlorides, etc., but neither iodine nor bromine. Dupasquier discovered in it both of these elements, which had generally escaped attention in consequence of their reaction, as soon as liberated, upon the sodium sulphide resulting from the decomposition of the sodium sulphate of the moss when charred. (*J. P. C.*, 3e sér., iii. 113.) The analysis made by Church in 1877 gave: mucilage, 55.4; water, 18.8; mineral matter, 14.2; albuminoids, 9.4; and cellulose, 2.2 per cent. The pectin Pereira thought peculiar, and proposed to call it *carrageenin*.

It is distinguished from gum by affording, when dissolved in water, no precipitate with alcohol; from starch, by not becoming blue with tincture of iodine; from pectin, by yielding no precipitate with lead acetate and no mucic acid by the action of nitric acid. Ch. Blondeau gives the name of *goëmine* to a substance obtained by boiling carrageen (*goëmon*, Fr.) for several hours in distilled water, and precipitating the mucilaginous liquid by alcohol. Flückiger, who analyzed this mucilage with care, found in it no sulphur, and only 0.88 per cent. of nitrogen. The drug itself yielded not more than 1.012 per cent. of nitrogen. (*Pharmacographia*, 2d ed., 748.) Haedicke, Bauer, and Tollens obtained, on extraction with water containing 0.6 per cent. of sulphuric acid, and further purification by alcohol, a small quantity of a crystalline compound which resembles galactose in its composition, in its action on polarized light, and in its behavior with nitric acid. On oxidation with nitric acid, the dry moss yields from 21.6 to 22.2 per cent. of mucic acid. Carrageenin is said to have been used as a substitute for acacia, under the name of *imitation gum arabic*; the latter occurs in three forms, white, light yellow, and yellow. They all have similar properties, swelling up like tragacanth when mixed with cold water, but not forming a clear solution unless the mixture be boiled, in this latter respect differing from tragacanth or albumen; iodine does not give a blue color, and alcohol does not precipitate the solution, even

when 50 per cent. of it is added. It has mild adhesive properties. (E. C. Federer, *Ph. Era*, 1887, 146.) The mucilage of Irish moss has come into considerable use as an emulsifying agent. (*Proc. A. Ph. A.*, 1887; *A. J. P.*, 1888, 170.)

Uses.—Chondrus is nutritive and demulcent, and, being easy of digestion and not unpleasant to the taste, forms a useful article of diet in cases in which the farinaceous preparations, such as tapioca, sago, barley, etc., are usually employed. It has been particularly recommended in *chronic pectoral affections, scrofulous complaints, dysentery, diarrhœa, and disorders of the kidneys and bladder*. It may be used in the form of decoction, made by boiling a pint and a half of water with half an ounce of the moss down to a pint. Sugar and lemon juice may usually be added to improve the flavor. Milk may be substituted for water when a more nutritious preparation is required. It is recommended to macerate the moss for about ten minutes in cold water before submitting it to decoction. Any unpleasant flavor that it may have acquired from the contact with foreign substances is thus removed.

Dose, four drachms (15 Gm.).

CHROMII TRIOXIDUM. U. S. (Br.)

CHROMIUM TRIOXIDE [*Acidum Chromicum*, Pharm. 1890, *Chromic Acid*, *Chromic Anhydride*]

(chrō'mī-i tri-ōx'i-dūm)

$\text{CrO}_3 = 99.34$

"It should contain not less than 90 percent. of pure Chromium Trioxide (chromic acid anhydride). It should be kept in glass-stoppered bottles, and great caution should be observed to avoid bringing it in contact with organic substances, such as cork, tannic acid, sugar, alcohol, collodion, etc., as serious accidents are liable to result." *U. S.* "Chromic Anhydride, CrO_3 , commonly termed chromic acid, is produced by the interaction of sulphuric acid and potassium bichromate." *Br.*

Acidum Chromicum, *Br.*, Chromic Acid, Anhydrous Chromic Acid; *Acide Chromique Cristallisé*, *Fr. Cod.*; *Acidum Chromicum*, *P. G.*; *Chromsaure*, *G.*; *Anhydride chromica*, *Acido cromico*, *It.*; *Acido cromico*, *Sp.*

This is not a true acid, but an acid anhydride. It may be obtained by the process official in the former British Pharmacopœia: "Bichromate of Potassium, 30 ounces (av.); Sulphuric Acid, 57 fluidounces (Imp. meas.); Distilled Water, a sufficiency. Dissolve the bichromate of potassium in a mixture of 50 fluidounces (Imp. meas.) of the water and 42 fluidounces (Imp. meas.) of the acid. Set aside for twelve hours, and decant the liquor from the crystals of acid sulphate of potassium that have separated. Heat the liquor to about 185° F. (85° C.), and add the remainder of the acid, and water sufficient to just redissolve any crystals of chromic acid that may have been formed. Allow to cool, collect and drain the crystals, and dry them on

porous tiles at a temperature not exceeding 100° F. (37.8° C.) in an air-bath. From the mother liquor more crystals may be obtained on evaporation." *Br.* 1885.

This process yields crystals which are more or less contaminated with sulphuric acid. *Vulpus* (*A. Pharm.*, 1886, p. 964) shows that commercial chromium trioxide sometimes contains as much as 7 per cent. of sulphuric acid, and that pure chromium trioxide is not scarlet in color, but dark brown-red and steel-glistening, and not deliquescent in ordinary air.

The best yield of pure crystals is said to be according to the method of Zettnow (*Pogg. Ann.*, cxliii. 471), in which 300 Gm. of potassium dichromate are mixed with 500 Cc. of water, and 420 Cc. of concentrated sulphuric acid added, and the mixture allowed to stand for twelve hours in order that the acid potassium sulphate may crystallize out. The mother liquor is then heated to from 80° to 90° C., and 150 Cc. of sulphuric acid added, together with enough water to dissolve the crystals of trioxide which at first separate out. After standing for twelve hours the liquid is poured off from the crystals which have separated, and a second and a third crop may be obtained by concentration. The crystals, having been drained upon a porous plate and washed with pure nitric acid, sp. gr. 1.46, are dried in a current of warm air. For a method by Duviller, in which barium chromate is treated by nitric acid, and chromium trioxide crystallized out of the mother liquor, see *A. J. P.*, 1873, p. 23.

Properties.—Chromium trioxide, as ordinarily seen in commerce, is in the form of anhydrous, acicular crystals, of a brilliant crimson red color and an acid metallic taste, deliquescent, and very soluble in water, forming an orange-red solution; but according to Kebler there may also be found in commerce an impure "chromic acid" made by mixing a solution of sodium dichromate with sulphuric acid and drying the product; it sometimes contains 60 per cent. of acid sodium sulphate (*Am. Drug.*, 1901, 344). The requirements of the U. S. Pharmacopœia (8th Rev.) are that even traces of sulphuric acid shall be absent, and that the color of the crystals be not scarlet. "Small, needle-shaped crystals or rhombic prisms, of a dark purplish-red color and metallic lustre; odorless; destructive to animal and vegetable tissues; deliquescent in moist air. Very soluble in water, forming an orange-red solution. When brought in contact with alcohol, ether, glycerin, and other organic solvents, decomposition takes place, sometimes with dangerous violence. When Chromium Trioxide is heated, its color darkens, and finally becomes black, but it is restored on cooling. At 192° to 193° C. (377.6° to 379.4° F.) it fuses to a reddish-brown liquid, which, on cooling, forms a dark red, brittle mass (often enclosing cavities filled with crystals), furnishing a scarlet powder. Above 250° C. (482° F.) it begins to decompose into green chromic oxide and free oxygen, and, after protracted heating,

leaves a residue of pure chromic oxide, which should yield nothing soluble in water. When warmed with hydrochloric acid, chlorine is evolved." *U. S.* "It is very soluble in water and in ether. Warmed with hydrochloric acid, chlorine is evolved. Mixed with cold alcohol (90 per cent.), aldehyde is produced, and a green residue remains. If placed in contact with relatively small proportions of either alcohol (90 per cent.), ether, glycerin, or some other organic matters, sudden combustion or explosion may ensue. 1 gramme dissolved in 50 cubic centimetres of water and acidulated with hydrochloric acid should afford only a slight opalescence with solution of barium chloride (absence of more than traces of sulphates)." *Br.* Chromium trioxide at a heat above the melting point, gives off half its oxygen, and is converted into the green sesquioxide, Cr_2O_3 .

It is a powerful oxidizing and bleaching agent, and gives up its oxygen with great facility to organic matter. The oxidation of weaker alcohol is attended with the production of aldehyde, recognized by the odor; that of stronger alcohol, by inflaming. "A solution of 1 Gm. of Chromium Trioxide in 100 Cc. of water, previously acidulated with a few Cc. of hydrochloric acid, should not be rendered turbid on the addition of 1 Cc. of barium chloride T.S. (absence of sulphuric acid). If 1 Gm. of Chromium Trioxide be dissolved in 100 Cc. of water, then 8.3 Cc. (8.28 Cc.) of this solution, when measured into a glass-stoppered bottle (of about 200 Cc. capacity), mixed with 2 Cc. of hydrochloric acid and about 1 Gm. of potassium iodide, after securely closing and shaking for a few minutes, should require, after diluting with 100 Cc. of water and adding 5 Cc. of starch T.S., not less than 22.5 Cc. of tenth-normal sodium thiosulphate V.S. to change the deep blue color to a light green (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 4 percent. of pure Chromium Trioxide)." *U. S.*

Uses.—As a germicide chromium trioxide is asserted by John Dougal (*L. L.*, Dec. 16, 1871), to surpass even phenol. A piece of fresh beef immersed in a solution of chromium trioxide containing only 1 part in 2000 of water became in two days quite black, in six as hard as wood, and at the end of three months remained perfectly free from mould or taint. It is a powerful coagulant of albumin, being, according to Dougal, 10 times stronger than phenol, 15 times stronger than nitric acid, and 20 times stronger than corrosive sublimate. It is, therefore, one of the best tests for albumin. Besides coagulating albuminous substances, it oxidizes decaying organic matter, combines with and neutralizes the escaping ammonia, and decomposes the hydrogen sulphide, reducing it to water and free sulphur. Chromium trioxide is used medicinally principally as an escharotic, in which capacity it acts by rapidly oxidizing and thus decomposing the tissues, while by the loss of one-half its oxygen it is itself con-

verted into the inert sesquioxide. It was first employed as a caustic by Sigmund of Vienna, on the recommendation of Heller. Used in substance, made into a paste with water, its action is not only exceedingly slow and gradual, but deeply penetrating. In saturated solution its action is less penetrating and less gradual. By using a solution more or less dilute, the effect may be graduated according to the degree desired.

It has been much used for the destruction of warts, condylomata, and various superficial growths or tumors, but caution is necessary, as it may give rise to a deep slough if too largely applied, and, according to Gubler, patients have been poisoned, through absorption, by its too extensive application. (*Ed. M. J.*, Sept. 1871, p. 281.) The occasional use of a five per cent. solution of chromium trioxide has been found in Prussia very useful in the treatment of sweating or tender feet, amongst the soldiery. Care should be taken not to prescribe chromium trioxide in combination with glycerin, or any substance which will cause it to part rapidly with its oxygen; a compounded prescription containing 8 grains of chromium trioxide and 1 drachm of glycerin exploded violently. (*Zeit. Oest. Apoth. Ver.*, June 1, 1875.) It is best to use a simple aqueous solution.

Dose, of chromium trioxide, should not exceed one-fourth of a grain (0.016 Gm.). It is very rarely, if ever, used internally.

Off. Prep.—*Liquor Acidi Chromici, Br.*

CHRYSAROBINUM. U. S., Br.

CHRYSAROBIN

(chrys-ă-rô-bî-nûm)

$\text{C}_{30}\text{H}_{36}\text{O}_7 = 494.46$

"A neutral principle extracted from Goa Powder, a substance found deposited in the wood of *Vouacapoua Araroba* (Aguiar) Druce (*Fam. Leguminosæ*). Chrysarobin should be preserved in amber-colored, glass-stoppered vials." *U. S.* "A substance obtained from Araroba by extracting with hot chloroform, evaporating to dryness, and powdering. It consists chiefly of a definite chemical substance also known as chrysarobin, but contains a varying proportion of chrysophanic acid." *Br.*

Chrysarobine, *Fr.*; Chrysarobinum, *P. G.*; Chrysarobin, *G.*; Crisarobina, *It.*

The definition of chrysarobin given by the *U. S. Pharmacopœia* makes it somewhat doubtful what is intended, but the statement of properties and characteristics has led us to consider the name as synonymous with that of chrysarobin of the *British Pharmacopœia*, which authority very properly recognizes under distinct headings Crude Chrysarobin (Goa Powder or Araroba) and the Purified Chrysarobin. (See *Araroba*, p. 187.)

Properties.—"A pale orange-yellow, micro-crystalline powder, tasteless, odorless, and irri-

tating to the mucous membrane. Specific gravity: 0.920 to 0.922. Soluble in 4812 parts of water, 308 parts of alcohol, 25 parts of benzene, 18 parts of chloroform, 114 parts of ether, 30 parts of amyl alcohol, and 230 parts of carbon disulphide at 25° C. (77° F.); soluble in 2170 parts of water at 80° C. (176° F.), and in 275 parts of alcohol at 60° C. (140° F.); soluble in dilute or concentrated solutions of potassium hydroxide, forming a red-colored liquid, with green fluorescence. Chrysarobin, when heated, contracts and forms a dark mass at 148° C. (298.4° F.), and melts at 157° C. (314.6° F.). When ignited it is partly sublimed and finally entirely consumed. In sulphuric acid it dissolves, forming a deep red solution. On pouring this liquid into water, Chrysarobin is deposited unchanged. On mixing 0.001 Gm. of Chrysarobin with 2 drops of fuming nitric acid, a red-colored mixture is produced, which turns violet on the addition of a few drops of ammonia water (distinction from *chrysophanic acid*, which produces a yellow-colored liquid). On shaking Chrysarobin with lime water for a few minutes, the liquid acquires a violet color (distinction from *chrysophanic acid*, which produces a yellow-colored liquid.) On adding a crystal of potassium dichromate to a solution of Chrysarobin in sulphuric acid, the red color is changed at first to green, then to purple, and finally to brown." *U. S.* The British Pharmacopœia requires that chrysarobin shall be entirely soluble in hot chloroform, almost entirely soluble in hot alcohol (90 per cent.), and that it shall partially dissolve in a solution of potassium hydroxide with the production of a deep reddish-brown color, and shall, when incinerated, not leave more than 1 per cent. of ash. (See *P. J.*, 1892, 543.) Chrysarobin in alkaline solution takes up oxygen readily, even from the air, and changes into chrysophanic acid according to the reaction:

The difference in physical properties between chrysarobin and chrysophanic acid is well described by Andouard. (See *Proc. A. Ph. A.*, 1895, 864.) When chrysarobin is distilled with zinc dust it yields *methyl-anthracene*, $\text{C}_{15}\text{H}_{12}$. Liebermann has since established clearly the relationship of chrysarobin to chrysophanic acid, as the latter is a dioxymethyl-anthraquinone, the former is a reduced quinone. Hence its affinity for oxygen, as the reduction products of the quinone class almost always tend to absorb oxygen and again go back to their original condition. Liebermann, in observing the chemical relationship of chrysophanic acid to commercial alizarine and purpurine, was led to study their reduction products (or leuco-compounds), and so discovered a class known as *anthrarobins*, having medicinal properties similar to chrysarobin. (See *Anthrarobin*, PART II.)

Lenirobin, made by the action of acetic acid on chrysarobin, and described as a tetracetate, and *Eurobin*, the triacetate, are re-

commended as substitutes for chrysarobin, having the advantage of not staining linen indelibly. (*M. R.*, 1898, 466.)¹

Uses.—When taken internally in sufficient amount, chrysarobin acts as a decided gastrointestinal irritant, producing large, very watery, brownish stools, and repeated vomiting without much nausea; it has however failed to secure a place as an internal remedy. Chrysarobin has long been used in South America and India as a remedy in *skin diseases*, but the attention of the general profession was first called to it in 1874 by Sir Joseph Fayrer. It is frequently applied in *psoriasis* and very *chronic eczema*, by being rubbed up with water into a dough, which is spread over the diseased spot after it is as far as possible freed from scales by washing. As soon as the dough is dry, it should be covered with a layer of collodion or solution of gutta-percha, and the whole allowed to remain for several days, when it is removed by washing and renewed. In using chrysarobin, care must be observed not to allow it to come in contact with the clothes, as it leaves an indelible stain. It is at present employed largely in the preparation of chrysophanic acid; its action is affirmed to differ from that of chrysophanic acid and to be largely the result of its strong affinity for oxygen, causing it to act as a reducing agent. In *hemorrhoids*, M. S. Kossobudskji claims to obtain extraordinary results. His method is to first wash off the hemorrhoids with a two per cent. solution of phenol or a one per cent. solution of creolin, and then, after thoroughly drying them with absorbent cotton, to apply two or three times daily a salve composed of chrysarobin, 12 grains; iodoform, $4\frac{1}{2}$ grains; extract of belladonna, 9 grains; vaseline, $3\frac{3}{4}$ drachms. In the treatment of internal hemorrhoids he employs suppositories composed of chrysarobin, $1\frac{1}{4}$ grains; iodoform, $\frac{1}{8}$ of a grain; extract of belladonna, $\frac{1}{4}$ of a grain; cacao butter, 30 grains; and sufficient glycerin to make a smooth mass. Chrysarobin is rarely used internally.

Dose, official, one-half grain (0.032 Gm.).

pentaria, Pursh, *Flor. Am. Sept.* p. 372.—*Actæa racemosa*, Willd., *Sp. Plant.* ii. 1139.—*Macrotys actæoides*, Raf.—*Macrotys racemosa*, Eaton's *Manual*, p. 288; *B. & T. S.*—This is a tall stately plant, having a perennial root, and a simple herbaceous stem, which rises from four to eight feet in height. The leaves are large, and ternately decomposed, having oblong-ovate leaflets, incised and toothed at their edges. The flowers are small, white, and disposed in a long, terminal, wand-like raceme, with occasionally one or two shorter racemes near its base. The calyx is white, four-leaved, and deciduous; the petals are minute, and shorter than the stamens; the pistil consists of an oval ovary and sessile stigma. The fruit is an ovoid capsule containing numerous flat seeds. The plant grows in shady or rocky woods from Canada to Florida, flowering in June and July.

Properties.—The dried root consists of a thick, irregularly bent or contorted body or caudex, from one-third of an inch to an inch in thickness, often several inches in length, furnished with many slender radicles, and rendered exceedingly rough and jagged in appearance by the remains of the stems of successive years, which to the length of an inch or more are frequently attached to the root.¹ It is officially described as follows: "Rhizome horizontal in growth, 2 to 15 Cm. long, 1 to 2.5 Cm. thick, with numerous thick, erect or ascending branches about 2.5 Cm. long, each terminated by a deep, cup-shaped scar; roots numerous, brittle, obtusely quadrangular, and about 2 Mm. thick; the whole brownish-black; fracture of rhizome horny, of root short, the rhizome exhibiting a rather large pith, surrounded by numerous whitish, radially sublinear xylem plates; bark thin, firm; the roots having a thick bark and usually a four-rayed wood; odor slight but heavy; taste bitter and acid." *U. S.* The roots "exhibit in transverse section from three to five wedge-shaped wood-bundles, separated by as many broad medullary rays. Both rhizome and roots are blackened by *test-solution of ferric chloride* (presence of tannic acid)." *Br.* The odor, though not strong, is peculiar and rather disagreeable, and is gradually lost with age. The root yields its virtues to boiling water. Tilghman found gum, starch, sugar, resin, wax, fatty matter, tannic and gallic acids, a black coloring matter, a green coloring matter, lignin, and salts of potassium, calcium, magnesium, and iron. (*A. J. P.*, vi.) It no doubt also contains, when fresh, a volatile principle, with which its virtues may be in some degree associated. Davis separated by distillation a small proportion of volatile oil having decidedly the peculiar odor of the root. He also found albumen, extractive, and silica. The sugar noticed by him was of the uncrystallizable variety, and the resin of two kinds, one soluble in alcohol but not in ether, the other soluble in

both these menstrua. (*A. J. P.*, xxxiii.) A crystallizable principle has been obtained by T. Elwood Conard from a strong tincture of the root by treating with solution of lead subacetate, which precipitated resin, tannin, and coloring matters, then filtering, and precipitating the lead by hydrogen sulphide in excess, and allowing the tincture to evaporate spontaneously; and, finally, having treated the residuary powder with petroleum benzin, afterwards washing it with water, dissolving it to saturation in strong alcohol, and treating the solution with alumina. The mixture was allowed to evaporate to a dry mass, which was nearly exhausted with alcohol. The solution, being allowed to evaporate, left behind a crystalline mass, somewhat resembling alum. This substance has little taste, on account of its extreme insolubility in the saliva, but in alcoholic solutions has very strongly the acid taste characteristic of the fresh root. The crystals are very soluble in cold, and more so in hot alcohol, soluble also in chloroform, and slightly so in ether. They are fusible and inflammable. They are neutral, possessing neither acid nor alkaline properties. Their effects on the system were not determined. (*A. J. P.*, 1871.) L. F. Beach (*A. J. P.*, 1876) obtained from commercial resin of *cimicifuga* (the so-called *cimicifugin* or *macrotin*) a crystalline principle by Conard's process. M. S. Falek (*A. J. P.*, 1884) found in the juice of the fresh plant a crystalline principle resembling the principle announced by Conard. On the other hand, neither F. H. Trimble (*A. J. P.*, 1878) nor Warder and Coblenz were able to obtain a crystalline principle, while C. S. Gallagher obtained crystals of cane sugar from the fluidextract. (*A. J. P.*, 1887.) In view of these facts, it would appear that the active principle is a resinous amorphous body. (See *Drugs and Medicines of North America*, vol. i.)

Uses.—In 1831 *cimicifuga* was introduced to the notice of the profession by Young. In overdoses it is said to cause general relaxation, vertigo, tremors, decided reduction of the pulse; occasionally it causes vomiting, but its emetic action is never violent, and is probably simply the result of a mild gastric irritation. It certainly, in large doses, produces giddiness, with intense headache and prostration. It has been found by R. Hutchinson to cause in frogs complete anæsthesia by a direct action upon the sensory side of the spinal cord. The same observer noted that toxic doses produce in mammals slowing of the pulse and fall of the arterial pressure, results which appear to be due in part to a direct depressant action upon the heart-muscle or its ganglia, in part to a paralysis of the vasomotor centre. It has been used in the past in *rheumatism*, *dropsy*, *hysteria*, *phthisis*, and various other affections, but at present is employed almost exclusively in the treatment of the *St. Vitus's Dance* of childhood, in which it is an efficient remedy. The *decoction* (1 ounce in a pint) was formerly much used in the dose of two fluidounces (60 Cc.), but is now entirely

¹For a detailed description of the microscopic character of the root, see *A. J. P.*, 1884, 460; also 1895, 121.

out of vogue. The dose of the *tincture* is one or two fluidrachms (3.75 to 7.5 Cc.). The *fluidextract* is, however, the best preparation; dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.) three or four times a day in water. The *extract* is efficient, and has the advantage that it can be administered in pilular form so as to be practically free from taste. The practitioners calling themselves eclectics use, under the name of *cimicifugin*, or *macrotin*, an impure resin obtained by precipitating a saturated tincture of the root with water; dose, a grain or two (0.065 to 0.13 Gm.). (See *N. J. Med. Rep.*, viii. 247.)

Dose, of powdered cimicifuga, twenty to sixty grains (1.3 to 3.9 Gm.).

Botanical History.

Though the Peruvian bark was introduced into Europe so early as 1640, it was not until the year 1737 that the plant producing it was known

to naturalists. In that year La Condamine, on a journey from Quito to Lima, through the province of Loxa, had an opportunity of examining the tree, of which, upon his return, he published a very complete description, with plate, under the name *Quinquina*, stating that three species were recognized. (*Mém. Ac.*, Paris, 1738, p. 226.) Four years later, Linné, without justification, proposed a new name, *Cinchona*, in honor of the Countess of Chinchon, who first made the bark known in Europe. Although the original name has been adopted by several authors, the synonym *Cinchona* appears in most writings, and the species are at present arranged under that name. Under the rules of nomenclature adopted at the Genoa Congress in August, 1892, the necessity of restoring the name *Quinquina* is avoided, and we retain the later name *Cinchona*. Linné recognized but one species, which he called *C. officinalis*, and this continued for a long time to be recognized by the Pharmacopœias as the only source of the Peruvian bark of commerce. But a vast number of plants belonging to the Linnean genus *Cinchona* were in the course of time discovered; and the list became at length so unwieldy and heterogeneous that botanists were compelled to distribute the species into several groups, each constituting a distinct genus, and all associated in the natural family of *Cinchonaceæ*. Seventy-three of those which may be denominated *False Cinchonas* have been enumerated by Weddell. The botanical characters distinguishing the true *Cinchonas* from the related groups, according to the classification of Bentham and Hooker, are exhibited in the following table:

Cinchonæ.—Corolla-lobes valvate, imbricate, or contorted. Ovary 2-celled, ovules very many in each cell. Fruit capsular. Seeds numerous, minute, vertical or ascending, peltate, imbricate, winged, albuminous; radicle almost always superior. Trees or shrubs, the stipules (except in *Hillebæ*) entire.

Subtribe I. EUCINCHONÆ.—Corolla valvate.

Subtribe II. HILLEBÆ.—Corolla imbricate or contorted.

I. EUCINCHONÆ.

*Placentæ adnate to the middle of the septum.

**Placentæ ascending or erect from the base of the septum.

***Placentæ pendulous from the apex of the cells.

† Capsule septicidal, the valves occasionally bifid.

†† Capsule almost always loculicidal.

†

1. *Cinchona*.—Panicles terminal. Corolla-lobes pubescent on the margins. Capsules dehiscent from the base upward.

2. *Cascarilla*.—Panicles terminal. Corolla-lobes papillose on the margins. Capsules dehiscent from the top downward.

3. *Kentia*.—Panicles or racemes axillary, interrupted.

I. *Cinchona*, L.

Calyx-tube turbinate, pubescent; limb 5-dentate, persistent. Corolla hypocrateriform, pubescent, the tube terete or nearly so, the limb 5-lobed, spreading, smooth within, the margin pilose, valvate. Stamens 5, inserted into the tube of the corolla, the filaments short or elongated; anthers included, or the apex exsert, dorsifixed, linear. Disk pulvinate. Ovary 2-celled; style slender, the branches short, obtuse, within papillose, inserted or sub-exsert. Evergreen trees or shrubs, the branchlets terete or 4-angled. Leaves opposite, petiolate. Stipules interpetiolar, the base glandular within, deciduous. Flowers white, purple, or flesh-colored, fragrant.

For our knowledge of these plants as they existed naturally, we are chiefly indebted to the

following botanists, besides La Condamine, of whom we have before spoken: Joseph de Jussieu, who in the year 1739, explored the country about Loxa, and gathered specimens still existing in the cabinets of Europe; Mutis, who in 1772 discovered *Cinchona* trees in Colombia, and afterwards, aided by his pupil, Zea, made further investigations and discoveries in the same region; Ruiz and Pavon, who in 1777 began a course of botanical inquiries in the central portions of Lower Peru, and discovered several new species; Humboldt and Bonpland, who visited several of the Peruvian bark districts, and published the results of their observations after 1792; Pöppig, who travelled in Peru so late as 1832, and published an account of his journey about the year 1835; Weddell, whose researches in Bolivia are so well known and have been productive of valuable information in relation to the Calisaya bark and allied species; while Karsten, Caldas, Martius, Ledger, Markham, and other intrepid explorers have in later times largely added to our information. The conclusions concerning the relations of the many forms, based upon the observations and collections of the above-named travellers, have undergone important modifications in view of the behavior of the plants under cultivation. The specific classification of the *Cinchonas* has always presented great difficulties, owing to the different relative values ascribed by different authors to the several structural characters. Under cultivation it has been seen that these characters are extremely variable, owing partly to the natural tendency of the species to develop strongly marked varieties, and partly to the great freedom with which they hybridize. While these tendencies have been stronger in the cultivated plants, they have evidently not been wanting in a state of nature. Thus we have come to place an entirely new estimate upon the supposed specific characters, and modern authors have been led to deny specific rank to many of the formerly accepted species. The extreme view is that of Otto Kuntze, who recognizes but four full species. This view is probably shared by no one, but Kuntze's general conclusions concerning the great extent of hybridization, and its influence in the production of new forms, are undoubtedly sound.¹ Rusby's studies in the Bolivian plantations led him independently to the same conclusions. Any specific classification, however carefully worked out, must be considered to some extent as matter of opinion merely.

¹ The principal sources of information bearing on this phase of the subject are the several reports of the plantations in Java, India, and Jamaica. Howard's *Quinology of the East Indian Plantations*, Markham's *Peruvian Bark*, Kuntze's *Arten, Hybriden und Cultur der Chinchobäume*, Hooper in the *Pharmacographia Indica*, several contributions by Trimen to the *Tropical Agriculturist*, and Rusby in the *Pharmaceutical Record*, Oct. 1887. The literature of the *cinchona* hybrids is hopelessly confused by the same name being frequently used by the different authorities for the different hybrids and the one hybrid having various names. Thus, *C. robusta* of Trimen is known in Ceylon as *C. lanosa*, and in the Neilgherry Hills as *C. magnifolia*, also as *C. pubescens*.

Probably the most satisfactory classification is that of Weddell, revised in 1870. (*Ann. d. Sci. Nat.*, 5th series, vols. xi. and xii.) Bentham and Hooker, in the *Genera Plantarum*, admit the existence of about 36 species, but this number appears entirely too large. The larger number of the species no longer possess more than a botanical and historical interest, as, under the changed conditions brought about by cultivation, their products are no longer collected for the market. The species which have been brought under cultivation for commercial purposes are alone named in the following list. Even this short list has been still further reduced as experience has determined the few species and forms which can be most profitably cultivated. Hence only the four species Nos. I, II, V, and VI of the list, which with their hybrids furnish almost all our bark at the present day, are here described:

- | | |
|-----------------------------|----------------------------|
| I. <i>C. officinalis</i> . | |
| var. <i>Condaminea</i> , | } yielding crown bark. |
| " <i>Bonplandia</i> , | |

| <i>C. micrantha</i> , | |
| <i>C. peruviana</i> , | |
| V. <i>C. Calisaya</i> , | } yielding yellow bark. |
| VI. <i>C. Ledgeriana</i> , | |

C. Calisaya, Weddell (*Hist. Nat. des Quinquinas*, p. 30, t. 3).—Tree tall, usually surpassing those about it, the trunk often more than 2 feet in diameter. Leaves petiolate, the blade ovate-oblong to slightly obovate, 3 to 7 inches long by 1 to 3 inches broad, obtuse, the base acute or slightly attenuated, very thin, smooth, and especially below, with a satiny lustre, above dark green, below emerald-green or deep purple-green, scrobiculate, the glands scarcely visible above. Stipules oblong, about equalling the petioles, very smooth, very obtuse. Panicles ovate to subcorymbose. Calyx pubescent, with a cup-shaped limb and short triangular teeth. Corolla rose-colored (In cultivation often white or nearly so), the tube cylindrical and about 4 lines long, the laciniae more deeply colored, the edges white-hairy. Stamens included. Capsule ovate, scarcely as long as the flowers. Seeds elliptical lanceolate, the margin irregularly fimbriate-toothed. Bolivia and Southern Peru, 4000 to 6000 feet. Source of the Calisaya or Yellow Bark. The species presents many forms, and two varieties are recognized.

Var. *Ledgeriana*, Howard, differs from the type chiefly in its thicker, narrower, oblong leaves, with attenuate base, often bluish-green below. It yields a thick and remarkably rich bark, and is probably the most valued of all the *cinchonas*. Specific rank has been strongly claimed for it.

Var. *microcarpa*, Weddell, is very similar to the last, with a firm leaf and short pod. It also yields a rich bark. It is not at all improbable that the accepted name "*Ledgeriana*" of Howard is a mere synonym for the older name *microcarpa* of Weddell. The var. *Josephiana*, so called, has in reality nothing to do with this species, nor with any other. It is distinct, and yields a thin and worthless bark. In Bolivia it is known as "*Pajinal*," and its presence in the plantation constitutes a serious difficulty. In appearance the plant is considerably like the *Ledgeriana*, with which it hybridizes freely, and the two, with their hybrids, have been apparently much confused in all plantations except those of Bolivia. *Ledgeriana* has a tall and slender habit, with a small crown, while *Josephiana* is shorter and broader, less symmetrical, and generally coarser. The branchlets of the former are blackish, those of the latter bright red.

C. succirubra, Pavon, Mss. (Howard in *P. J.*, Oct. 1856, p. 209, with a figure). Extreme size even greater than that of the last. Branches silvery. Petiole pubescent, leaf ovate to oval, acute with a very short point, the base more or less narrowing, often 6 by 9 inches, dark green and smooth above,

below paler and pubescent to a variable degree, especially on the veins, not scrobiculate, the margin slightly revolute. Stipules entire, oblong, obtuse, subamplexicaul. Flowers much as in the last, but rather smaller. Fruit lanceolate. Western slopes of Mt. Chimborazo. The source of the Red Bark.

C. officinalis, Linné (*Sp. Pl.*, ed. 1, p. 172).—Petioles smooth, cylindrical, and, like the veins, reddish; blade 4 to 5 inches long, varying from broadly oval to lanceolate, acute at both ends, the margins usually recurved, smooth and deep green above, paler, but bright green below, scrobiculate, the principal veins pubescent. Stipules equalling the petioles, ovate, acute, entire, pubescent. Flowers and fruit much as in *C. Calisaya*. Widely distributed in the equatorial Andes, at an elevation of from 5000 to 7500 feet. The source of the barks known as Pale, Crown, Loxa, Cuenca, and Huanoico. This is the original species, upon which the genus *Quinquina* or *Cinchona* was founded. All things considered, it is, perhaps, to be regarded as the principal species of the genus. Its variability is extreme, and it is doubtful if any two authors can be found who agree perfectly as to its limits. The forms of no other species have suffered such vicissitudes of nomenclature as have those of *C. officinalis*. Those which to one author appear easily included within it, in the hands of another serve as types of quite a group of species and varieties. The classification of our present supplies of bark is, however, not materially affected by these considerations.

The specific variations produced by hybridization in the above characters may not be here considered, though it may be stated that they are entirely characteristic. The parentage of a hybrid is ordinarily fully and strongly indicated in its appearance. As a rule, also, the alkaloidal yield takes a mean between that of the parents, but sometimes this is conspicuously not the case.

Geographical Distribution.

The genuine *Cinchona* trees are natives exclusively of South America. In that continent, however, they are widely diffused, extending from the 19th degree of south latitude, considerably south of La Paz, in Bolivia, to the mountains of Santa Marta, or, according to Weddell, to the vicinity of Caracas, on the northern coast, in about the 10th degree of north latitude. They follow, in this distance, the circuitous course of the great mountain ranges, and for the most part occupy the eastern slope of the second range of the Cordilleras. Except northward from Guayaquil, or a very little to the southward of that latitude, the growth of the *Cinchona*, other than upon the eastern slopes of the Andes, is impossible even under cultivation. Elsewhere both the western slope and the plateau are entirely too dry or too cold for these plants, which require a moderate and equable temperature and an abundant and fairly constant supply of water. Irrigation cannot supply the place of a humid climate, for the atmosphere as well as the soil must be well charged with moisture. A certain amount of dry weather is, however, required for the ripening of the capsules. Free drainage is an important condition. Cross and others, who have personally inspected the region in the Andes where the best barks are obtained, have found the *Cinchona* trees only on the well drained slopes, and never on wet ground. With regard to temperature, Cross found that in the region of the *C. officinalis* the variation was

from 34° to 70° F., a fall below 40° or a rise above 65° being rare, and the mean range being from 45° to 60°. Humboldt and Caldas place the figures several degrees higher.

For the Red Bark region, Spruce gives the following table:

Mean minimum	61½° F.
Mean maximum	72½°
Highest observed	80½°
Lowest observed	57°
Mean daily variation	10½°

For the Calisaya region, Markham gives the following table:

Mean temperature	69½° F.
Highest observed	75°
Lowest observed	56°
Mean daily variation	10½°

An environment suitable for the *Cinchona* is adapted to such plants as the most elevated of the palms and bamboos, the tree-ferns, arborescent Melastomaceæ, fuchsias, begonias, epiphytic orchids, and the *Erythroxylon Coca*. The limits of altitude and climatic conditions are closely drawn. In the most southern districts, the trees descend to about 2500 feet, while in the warmest regions they scarcely ascend to the 10,000-foot level. The individual species are for the most part rigidly restricted as to altitude and latitude, and, indeed, it has not always been found easy to detect the climatic conditions which would cause one species or variety to thrive while another very near it would languish. This is especially true of the more valuable forms.

It is to be noted that at present the stocks of wild barks have been enormously reduced, as detailed under Commercial History. Indeed, in certain sections, as the Calisaya district, the tree was practically exterminated in the wild state, so far as relates to a bark supply. From the far interior, however, occasional bales of wild Calisaya have been received. The low price of cultivated bark since 1885 has resulted in checking the destruction of the wild trees, which have begun again to multiply, so that they may possibly become once more common or even abundant. The Crown Bark region of Ecuador is still fairly productive, and in Colombia and Venezuela there are vast supplies of more or less inferior barks which await some favorable change in the market—never very likely to take place—that will render their collection profitable. Even at present a limited and irregular supply of one of these barks is furnished. With the exceptions here noticed, our present supplies of bark are entirely the product of cultivation, to which, therefore, we must give our chief attention.

Cultivation and Production.

The alarming prospect of the failure of the supply of *Cinchona* bark (see Commercial History) induced Europeans, about the middle of the nineteenth century, to turn their attention to the possibility of introducing the trees to cultivation. So early as 1737, La Condamine had collected a large number of young plants, with a view of conveying them to Europe; but, after having descended the Amazon in safety for more than a thousand leagues, they were

washed overboard, near the mouth of that river, from the boat containing them, and were all lost. After this failure, though the idea of transplanting the *Cinchonas* was occasionally suggested, nothing was done until 1846, when Weddell, now celebrated for his successful exploration of the region of the Calisaya bark, sent some seeds to France, which were planted with success in the Jardin des Plantes, and thus supplied some of the conservatories of Europe with specimens of the plant. But the first successful effort with a view to great practical results was made in 1853 by the Dutch government, by which Hasskarl, formerly superintendent of the Botanical Garden in Java, was sent to South America on this important mission. A number of young *Cinchona* plants were forwarded by him directly across the Pacific to Batavia, which they reached before the close of 1854. From these, and from seeds obtained from other sources, which were planted in the mountains of Java, in sites selected for their supposed conformity in climate with the native locality of the *Cinchona*, have sprung the most important plantations now in existence.

Stimulated by the suggestions of Royle, and by the partial success of the Dutch, the English government engaged, in 1859, the services of Clements R. Markham, who proceeded to Bolivia, in South America, and, after almost incredible hardships, arising partly from the nature of the country and partly from the jealousy of the native authorities, succeeded in collecting and transmitting to England upwards of 400 Calisaya plants. Most of these, however, were so much injured on their way from England to India, by the excessive heat of the Red Sea, that very few, on their arrival in Hindostan, had sufficient life remaining to grow when planted. Happily, the deficiency was supplied by seeds of *C. Calisaya* sent from Java, where they were produced, to Calcutta, at the request of the English Governor-General. While Markham was in Bolivia, other agents were collecting other species in Peru and Ecuador, whence seeds of the pale and red bark *Cinchonas* reached India, and, being planted in the selected sites, proved to be very productive.

Careful attention to the conditions of growth enumerated under Geographical Distribution was found essential in the selection of sites for the plantations. Those selected were near the Sanitary Station of Ootacamund in the Neilgherry Hills of Southern India, at heights varying from 5000 to 7450 feet. These positions unite the peculiar characters of the native region of the *Cinchonas* in the Andes, not only as regards elevation and latitude, but also as to atmospheric moisture. Other sites were selected for experimental plantations, and since the first introduction of the *Cinchona* trees, their culture has been extended to various points from Hakgalla, in the island of Ceylon, to the Himalaya Mountains,—as in the Wynaad, the Coorg, the hills of Travancore, and especially at Peermade in the Presidency of Madras; in

Sikkim and Darjeeling in the Presidency of Bengal; at Lingmulla in the Presidency of Bombay; and in the valley of Kangra in the Punjab,—from the southern to the northern extremity of British India. Outside of India and Ceylon, culture by the British has been undertaken in the West Indies, particularly Jamaica, in Guiana, and in the Fiji Islands. The first plants taken by Weddell from Peru to Paris all perished, but the French afterward established plantations in the Isle of Bourbon, at Guadeloupe, and in Algiers, none of which are known now to exist. The Portuguese have established plantations upon the west coast of Africa, and these now yield considerable quantities of bark. Very extensive plantations have been formed, chiefly by the Germans, in Bolivia. A rather large plantation in Colombia is now old enough to be productive. In Mexico and Central America various attempts to introduce the industry have been made. The question of introducing it into the United States has frequently been raised, but it may be stated that there is no spot in North America where the conditions warrant the slightest hope of success in this direction.

The history of *Cinchona* cultivation affords a striking illustration of the importance of government aid in the establishment of a new industry of this kind. The early and repeated disappointments and failures, owing to the natural obstacles in the way of securing stocks, and to an almost total ignorance of the conditions determining the successful propagation and growth of the plant, and the composition of its bark, were such as to have discouraged the most hopeful of private enterprises. Repeated and expensive expeditions were necessary before the first transplantings were accomplished, and these stocks were preserved and propagated only through the instrumentality of well appointed public gardens and plantations. In Java, after these early difficulties had been surmounted and success apparently attained, it was found that owing to cross fertilization much of the progeny was entirely worthless, and the work of propagation had to be begun anew. The same difficulty was encountered elsewhere, and the slow and expensive method of propagation by cuttings was largely resorted to. In Ceylon the public were slow to become interested, and the officials were obliged not only to give away the young plants, but to solicit experiments with them as a personal favor. In Jamaica a hurricane visited the young and flourishing plantations and almost completely destroyed them. But at length, in spite of all, not only were thriving and permanent government plantations established, but private capital and enterprise upon a vast scale were enlisted. It is not probable that the forests of South America will ever again contribute a very important quota of the world's *cinchona* supply, or that the plant can be cultivated elsewhere than in Southern Asia with commercial success on a large scale. The question of commercial suc-

ness is dominated not simply by climatological surroundings but also by the price of labor. It is stated that both in India and Java the natives who work in the cinchona forests are paid from one dollar to one dollar and seventy cents per month, without food, according to the age and sex. The ability to extract the bark upon the spot is capable of largely counterbalancing a lack of market facilities; but it so happens that this advantage also inures to the benefit of the Eastern countries. Originally undertaken in India for the purpose of affording a cheap antiperiodic (the crude alkaloids known as "*febrifuge*" or "*quinetum*")¹ home extraction has become a most important industry, and has assumed various forms. Through the influence of the above conditions the locations of the important industry of Cinchona cultivation have been gradually wrought out, and at present about four-fifths of the cinchona barks of the world, outside of India, are furnished by Java. The first shipment from Java was of 900 pounds, in 1869. In 1900 it was 5,390,000 kilogrammes, in 1904, 7,225,000 kilogrammes. It is to be remembered that a great part of the Indian product is not exported.

Much interest has in the past attached to the selection of species of Cinchona for cultivation. In 1889 the trees upon 1779 acres of government plantation in Madras were as follows: *officinalis*, 981,918; *hybrids*, 655,856; *succirubra*, 70,693; *Calisaya*, 273; other kinds, 915, while upon 3000 acres of government plantation in Bengal, with six million trees, *calisaya* and *hybrids* represented by far the greater part. In Java in 1891, according to the government report, there were of *Ledgeriana*, 2,659,000; *succirubra*, 1,076,000; *officinalis*, 52,900; *Calisaya*, 2200; *lanceifolia*, 1500. According to the report of Verne, to the French Minister of Instruction in 1903 at present the favorite species of cinchona is both in India and Java, *C. Ledgeriana*, which it will be remembered is simply a variety of *C. Calisaya*, and is said to be the richest in quinine of all barks. The small supply of wild bark coming from South America is believed to be chiefly derived from *C. officinalis* and its varieties. In the plantations of South America the attempt is made by the planters to keep the *C. Calisaya* pure, hybridization being avoided as far as possible.

Methods of Cultivation.

The history of Cinchona cultivation teems with evidence as to the difficulty of obtaining pure seeds, owing to the tendency of the plants towards cross-pollination. In every locality where the industry has been established has

the disgust of the gardener been excited by the discovery that the plants which he had reared with great care, and upon which he had based great expectations, were contaminated by the admixture of foreign pollen. This was especially true in case of the earlier attempts, before this tendency had become known. Experience at length established the fact that absolute isolation of the seed-trees was essential. One of the curious developments of these experiments was the fact, already referred to, that the value of the progeny was not always assured by the value of its parentage. Some of the hybrids, even when least expected, would develop a surprisingly rich yield; and this tendency has been utilized to develop the most valuable stocks in existence. So certain is it that some of the plants from the best seed will prove worthless, that the careful selection of the seedlings while young is deemed necessary, and in South America, at least, all planting contracts are based upon this expectation, the contractor not being paid for his work until the plants have become old enough to show with certainty the proportion of good plants contained. Both in the selection of the young seedlings and the acceptance of the plantation, the test of identity is found in the leaf. Propagation by cuttings, extensively practised in some localities, has been found too slow and expensive to become general. A thorough preparation of the soil is as beneficial in the case of Cinchona as in that of other crops. Thorough tillage after transplantation is also essential, a free growth of weeds meaning destruction to a large number of the young trees. The cultivation of a secondary crop between the rows of trees is, however, practicable. A large percentage of profit depends upon the selection of a suitable age for collecting the bark. There comes a time when the use of the ground for starting a new crop is more valuable than the gain by permitting the present crop to remain, and after some years an actual deterioration of the bark sets in. This age is not the same for all the trees in the plantation. Several years' difference may occur in the maturing of trees germinated at the same time. In the case of *Calisaya* it occurs at from 6 to 9 years from seed, and its indication is the "chicken-leg" scalliness of the bark, as described under Classification. The "*officinalis*" matures somewhat less early. In the Bolivian plantations the most experienced hand is selected as the marker, and the cutters follow him, peeling the trees which he has indicated. How far these careful methods of selection are followed elsewhere, the writer is not informed.

Four principal methods of collecting the bark are in vogue, these being variously modified in different sections. The first is *uprooting*, the most primitive, by which the trees are simply uprooted at the proper age, and the ground replanted. The barks of root, stem, and branches are preserved and marketed separately. The second method is *coppicing*, by

¹ In Java the powdered bark is thrown into a 5 per cent. solution of caustic soda at 50° C. treating this with Java petroleum, separating, treating the petroleic solution with water acidulated with sulphuric acid and evaporating; the result is said to be a quinine containing less than 1 per cent. of cinchonine. (*J. P. C.*, 1901.) It is imported largely into the United States—50,000 kilogrammes a year—but on account of its yellow color is chiefly employed in the making of proprietary medicines rather than tablets.

which, after peeling a quill from the lower portion of the trunk, the latter is cut a few inches from the ground and the remainder of the stem bark and the branch bark are removed. The "coppice" is formed by a second growth of two shoots from each of the stumps. A second coppice is commonly grown, and this is harvested by uprooting. By the third method, *scraping*, the outer bark is scraped off, leaving the liber untouched. This has been found especially applicable to young trees, in which the second growth of bark is rapidly formed and contains 20 to 30 per cent. more alkaloid than that which has been taken off. It seems to be a general opinion among the planters that scraping checks the growth of the tree after it is 5 years old, so that from 3 to 5 years is the age at which it is best practised. The fourth method is known as *mossing*. It having been noticed that the *Cinchona* alkaloids, especially in any other form than that of sulphate, were apt, on exposure to the direct light of the sun, to become reddened by the generation of coloring matter, at the expense of the alkaloid, it was a very natural inference that a similar change might take place in the living plant, as a consequence of which the proportion of alkaloids they were capable of producing might be greatly diminished. It was also observed that the bark upon that side of the tree where the sun struck it was less rich than that upon the shady side. To obviate this presumed effect, MacIvor was induced to make the experiment of covering the stems of the growing trees with a layer of moss, so as to completely protect the bark against the influence of sunlight. The result was favorable beyond all expectation, and the yield of alkaloids in the bark thus protected is said to be doubled, tripled, or increased even in larger proportion. A tree can thus be made continuously productive; for if a slip is removed longitudinally from the trunk, from top to bottom, by covering the decorticated portion with moss, the bark is renewed at least as rich as previously in the alkaloids, while from time to time other strips may be taken, until the whole of the old bark is removed, and the new ready for removal by a repetition of the same process; and the tree is thus preserved indefinitely, probably for the whole normal length of its life. Hooper says that renewed bark is always of greater value than the mossed, and mossed than the natural, so long as the trees are under 20 years old, for it has been found that after that time the bark ceases to thicken, and the alkaloids remain stationary or even decrease. Perhaps 20 years is even too old. The practical difficulty with the process is that it requires skilled workmen, not always attainable, and hence the "coppicing system" still largely prevails in India. The supplies of suitable moss accessible to the Indian plantations having become exhausted, recourse was had to grass, old rags, paper, straw, hay, etc., all of which have been found to serve the same useful purpose. Regarding

the relative amounts of the different forms of bark, we note that Ceylon returns show the following general percentages ranging over a period of four years: renewed, 30 per cent.; natural stem, 25 per cent.; root, 5 per cent.; branch, 40 per cent. Not much is to be learned from these figures, as they must, in the nature of the case, differ very widely according to the method of collection employed. As to composition, it was found that the branch bark (probably due partly to the quantity of wood which inevitably comes away with it) was but one-third as rich in quinine as the natural stem bark, while the renewed bark was twice as rich as the natural stem bark. The root bark was about equal to the natural stem bark. It is difficult to understand the last statement, in view of the well-known fact that an assay of the bark of stem and root of any one tree shows the latter to be much richer. The low result may have been due to the presence of wood, earth, or other foreign matter.

The methods of packing the bark have also undergone important modifications since the early days of cultivation. The extensive adulteration practised when the wild bark brought very high prices led to a demand for it in large pieces which could be readily and quickly examined; hence the appearance of the large *tabla* and *quill* forms, the latter afterwards becoming the standard for the cultivated bark. The bark of the trunk, and sometimes of the branches when very large, is cut into two-foot lengths, and each length removed in a single piece, which in drying rolls up to form a quill. Such peeling can of course be successfully practised only at the appropriate season of the year. The bark or the roots, branches, and dead or dry trunks must be removed by chipping, scraping, or shaving, commonly the latter. The quills, after thoroughly drying, are carefully packed in bales, or preferably in boxes, to avoid breakage, and are marketed in packages of from 100 to 250 pounds. Large quantities of cultivated bark are still marketed in this way, but, increasing competition having lowered prices so that economy in freight has become a very important item, most of the bark is now broken up, and its bulk even reduced by high pressure, and in fact only a trifling amount of wild South American bark comes into commerce. In the year 1897, South America sent to the United States a little over 30,000 pounds of cinchona; in 1901, 6552 pounds; in 1902, 5405 pounds; and in 1903, 7931 pounds, of which $\frac{1}{4}$ came from Venezuela. The effect of cultivation of cinchona upon the world's civilization has been most marked; immense as was the area which yielded the original wild bark its depletion had become very evident before the beginning of the cinchona plantations, and had it not been for these plantations the trees would by this time have been practically extirpated, and quinine only available for the very rich. Cultivation has very greatly increased, not only the quantity but also the quality of bark. For some

years, in India the attempt was made largely to increase the general average in total alkaloids rather than in quinine, so as to increase the production of the impure alkaloids which are so largely used as febrifuges in the British East Indies. Of recent years, however, even in India, efforts have been directed to the obtaining of quinine rather than of inferior alkaloids. The barks of Ceylon have always been of poor quality, while those of Java to-day are probably the best that have ever been put upon the market. The effect of the efforts of arboriculturists is well shown by the facts that in 1889 the average percentage of quinine in Java bark was 4; in 1893 it had risen to 4.6; while in the five years, from 1900 to 1904 inclusive, the average quinine percentage of all the Java barks sold in the Amsterdam market was 5.37. The result does great credit to Java, for during the early history of her bark enterprise her plantations were stocked with discouraging quantities of poor or even worthless barks, which have been eliminated by the most steady enterprise and patient industry.

Commercial History.

The above general history of Cinchona leaves little necessary to be said of its commercial history, except to deduce from the facts already presented certain practical conclusions showing the present conditions of supply and demand, these bearing especially upon our concluding remarks concerning pharmacognosy and classification.

For more than a century after Peruvian bark came into use, it was procured almost exclusively from the neighborhood of Loxa. In a memoir published in 1738, La Condamine speaks of the bark of Riobamba, Cuenca, Ayavaca, and Jaen de Bracomoros. Of these places, the first two, together with Loxa, lie within the ancient kingdom of Quito, at the southern extremity; the others are in the same vicinity, within the borders of Peru. The drug was shipped chiefly at Payta, whence it was carried to Spain and thence spread over Europe. Beyond the limits above mentioned the Cinchona was not supposed to exist, until, in the year 1753, a gentleman of Loxa discovered it, while on a journey to Santa Fé de Bogota, in numerous situations along his route, wherever, in fact, the elevation of the country was equal to that of Loxa, or about 6500 feet above the level of the sea. This discovery extended through Quito into Colombia, as far as two degrees and a half north of the equator. But no practical advantage was derived from it; and the information lay buried in the archives of the viceroyalty until subsequent events brought it to light. To Mutis has been awarded the credit of making known the existence of the Cinchona in Colombia, he having claimed its discovery in the neighborhood of Bogota in 1772. Recently great doubt has been thrown upon the justness of this claim. A botanical expedition was afterwards organized by the

Spanish government, with the view of exploring this part of their dominions, and the direction was given to Mutis. Its researches eventuated in the discovery of several species of Cinchona in Colombia, and a commerce in the bark soon commenced, which was carried on through the ports of Carthagena and Santa Marta.

To these sources another was added about the same time (1776) by the discovery of the Cinchona in the centre of Peru, in the mountainous region about the city of Huanuco, which lies on the eastern declivity of the Andes, north-east of Lima, at least six degrees south of the province of Loxa. To explore this new locality, another botanical expedition was set on foot, at the head of which were Ruiz and Pavon, the distinguished authors of the *Flora Peruviana*. These botanists spent several years in that region, during which time they discovered numerous species. Lima became the entrepôt for the bark collected around Huanuco, and hence probably originated the name of *Lima bark*, so often conferred, in common language, not only upon the varieties received through that city, but also upon the medicine generally.

Soon after the last mentioned discovery, two additional localities of the Cinchona were found; one at the northern extremity of the continent, near Santa Marta, the other very far to the south, in the provinces of La Paz and Cochabamba, then within the viceroyalty of Buenos Ayres, now in the republic of Bolivia. These latter places became the source of an abundant supply of excellent bark which received the name of Calisaya. It was sent partly to the ports on the Pacific, partly to Buenos Ayres.

The consequence of these discoveries was a vast increase in the supply of bark, which was now shipped from the ports of Guayaquil, Payta, Lima, Arica, Buenos Ayres, Carthagena, and Santa Marta. At the same time the average quality was probably deteriorated; for, though many of the new varieties were possessed of excellent properties, yet equal care in superintending the collection and assorting of the bark could scarcely be exercised in a field so much more extended. The varieties now poured into the market soon became so numerous as to burden the memory if not to defy the discrimination of the druggist, and the best pharmacologists found themselves at a loss to discover any permanent peculiarities which might serve as the basis of a proper and useful classification. The restrictions upon the commerce of South America, by directing the trade into irregular channels, had also a tendency to deteriorate the character of the drug. Little attention was paid to a proper assortment of the several varieties, and not only were the best barks mixed with those of inferior species and less careful preparation, but the products of other trees, bearing no resemblance to the Cinchona, were sometimes added, having been artificially prepared so as to deceive a careless observer. The markets of this country

were peculiarly ill furnished. The supplies, being derived chiefly, by means of a contraband trade, from Carthagera and other ports on the Spanish Main, or indirectly through Havana, were necessarily of an inferior character; and most of the good bark which reached us was imported by our druggists from London, whither it was sent from Cadiz. A great change, however, in this respect took place after the ports on the Pacific were opened to our commerce. The best kinds of bark were thus rendered directly accessible to us, and the trash which formerly glutted our markets became in great measure excluded. Much bark was also imported from Carthagera and other ports of the Caribbean Sea, being brought down the Magdalena River from the mountains of Colombia; and an additional source of supply was opened through the Amazon, though this bark was of inferior quality. More or less perplexity attending the recognition of the barks continued until after the firm establishment of the bark culture and the cheapening of the price, to the exclusion of the worthless varieties, as already described.

The price of the bark was as irregular and uncertain as its quality. The Cinchona forests, being in thinly-inhabited districts, did not, for the most part, belong to individuals, but were open to the enterprise of all who chose to engage in the collection of the bark. As a consequence, the operations were carried on without reference to the future condition of the interest, and most wasteful modes of procedure resulted at length in the almost complete destruction of the source of supply, and in fabulous prices—\$350 to \$450 per cwt.—being paid for the better grades of bark. To this result private speculation, official intrigue, and national greed all contributed. Various attempts were made to utilize the leaves, flowers, and wood of the tree, but these were found not to contain the active constituents in sufficient amount. Fortunately, cultivation has about abolished all the evils and perplexities attending this trade, and has given us a steady and practically unlimited supply of the finest bark at prices which, compared with those above referred to, are merely nominal.¹ Although this great fall in price resulted in a great financial depression and even brought disaster to some planters whose expenses were greater than could be returned at the rates then prevalent, yet, on the whole, the business has been very profitable, having paid for itself several times over. The depression in 1894 is supposed to have been brought on largely by the very heavy marketing by Ceylon, amounting, Ferguson says,

to 82,000,000 pounds in seven years. Much of this marketing was in turn due to a craze for tea planting, on account of which, from 1885 to 1888, 22,000 acres of cinchona were uprooted, throwing upon the market 35,000,000 pounds of bark. A. C. Meyjes, who has devoted much study to the commercial history of Cinchona bark, estimated the annual consumption for 1894 at about 15,000,000 lbs.

One of the most important developments of the modern bark trade is the fixing of the price in accordance with the quality as determined by assay. The most accurate method of selecting a characteristic sample for assay is a subject which has received much study, without the discovery of any method which does not depend for its value upon the discrimination and care exercised in its employment. The plan which is regarded as the safest is to take a given weight, say 8 ounces, from the inner portion of each package constituting the lot, mix and powder the whole of it, and furnish to applicants the required amount of the resulting powder. If any portion of any bale or bales is damaged, care is taken to add a proportionately large fragment of such portion. The bark is then recorded as containing so many units, a "unit" being each per cent. of quinine contained in a pound of bark. In rich bark the units are of course worth more than in poor, owing to the increased yield of alkaloid for the same cost of manufacture.

In the United States, at least, some difficulty has been experienced by druggists in securing the better grades of bark at regular rates, owing to the activity of the manufacturers in draining the market of the most desirable stock. The finer appearing packages of unbroken bark, having been marketed at greater cost, are necessarily held at higher prices. Possessing no special value for manufacturing purposes, these fall to the share of the druggist, but at higher prices than broken bark of the same richness. This fact has led to the recognition of two distinct classes, known as *manufacturers' bark* and *druggists' bark*. Druggists' bark, though in quills or unbroken pieces, and of a much finer appearance than manufacturers' bark, is on the average, inferior in quinine percentage. The druggists' bark finds its entrance into commerce through various channels but the bulk of the cinchona trade, including practically all that is known as manufacturers' bark, centres in Amsterdam and London; of these marts that at Amsterdam is much the more important; in 1903 there were imported into the United States 4,000,000 pounds of cinchona bark, of which 3,000,000 pounds came from the Netherlands, 900,000 from England, and 100,000 from other parts of the world. The bark which is sold in Amsterdam comes almost exclusively from Java; that in London from India, Ceylon, and South America. Manufacturers' bark is sold, without respect to its physical characters or place of origin, entirely by its chemical analysis, the buyer in London being furnished with

¹ One writer, referring to the results of the Ceylon production, says, "We swamped the markets of the world, conferring simultaneously untold benefits on humanity by compelling a reduction in the price of Howards' quinine of more than 75 per cent. . . . Simultaneously we have reduced the value of the unit of quinine in bark against ourselves and all other producers from 2s. in 1880 to 3d., and even 1½d., though now 2d."

samples of the different lots of the bark sufficient time before the sale to enable him to make his own analysis, while in Amsterdam the percentage of quinine sulphate in any lot is given in the catalogue and often tagged upon the bale. In London lots are sold by the pound; in Amsterdam by the kilogramme. The dealers calculate the price by the quininic value of the sample. The so-called unit of price of sale is in England the price paid per pound, divided by the percentage of quinine in the bark bought; thus, if $4\frac{1}{2}$ pence per pound has been paid for bark containing 3 per cent. of quinine then the broker marks his unit for that particular lot as $1\frac{1}{2}$ pence per pound. The Dutch unit is calculated in similar manner but in Dutch cents and in decimal weights. A comparison of the cost of Dutch and of English barks bought may be based upon the fact that a Dutch unit of 11 Dutch cents per half kilo is exactly the same as an English unit of $2\frac{1}{2}$ pence per pound.

Formation of the Alkaloids.—In a very careful series of experiments made at the Java governmental cinchona plantations, Lotsy (*Bull. Inst. Botanique Buitenzorg*, 3, 1900,) found that the seeds of *C. succirubra* and *C. Ledgeriana* contain no alkaloids, but that these alkaloids appear in the cotyledons shortly after they become green. They exist chiefly in the bark in combination with a tannic acid. Lotsy found that the percentage of alkaloids is ten times greater in young than in old leaves; also that the petioles are richer in alkaloids than is the blade, and that the branch bark contains more than the trunk bark, and that the root bark is practically free from alkaloids. During the active life of the parenchymatous cells of the leaves, wood, and cortex, the alkaloids can always be found in the active protoplasmic contents, but when these cells pass into the inactive condition, are deposited in the cell-walls. The alkaloids found in the leaves are, however, never crystalline, hence it would appear that these organs produce by direct synthesis, probably as the result of the action of cinchonic acid with ammonia, a fundamental alkaloidal base, which probably in the cambium layer of the tree, and during its deposition in the growing bark, is elaborated into the true cinchona alkaloids.

Classification.

Extreme difficulty attended the earlier attempts to classify the Cinchona barks of commerce,—difficulties not probably encountered elsewhere in the Materia Medica. The varieties have, however, been reduced to a very few, and the whole subject decreased greatly in importance by the chemical method of the sale now in vogue. Most of the discarded barks will be found described in previous editions of this work. We find it necessary to enumerate and describe here only the Pale bark, from *C. officinalis*, the Red bark, from *C. succirubra*, the Yellow bark, from *C. Calisaya* and its var. *Ledgeriana*, and the Hard Yellow or Maracaibo bark, and to refer briefly to the hybrid forms.

First, a few words concerning the forms in which Cinchona bark occurs. We have (1) the large flat pieces or chips of irregular shape and size,—this referring at present almost wholly to the Maracaibo variety; (2) the small chips or broken bark, referring in large part to the root bark, and to other bark broken for close packing; (3) the shaved bark, referring to some root bark and to stem bark taken from dry stems, but chiefly to branch bark; (4) the quill bark, referring to natural bark taken from the stem and root in quill form, this including the uncultivated pale bark and all the varieties of cultivated bark; and (5) the renewed and mossed bark, which may be of any cultivated variety. The classification of all varieties and forms into druggists' and manufacturers' barks enables us to dispense in great part with a description of some of these forms. The manufacturer cares nothing for form, appearance, or structure, and but little for the variety of his supplies. He is interested wholly in its composition, and this he determines by assay. For this reason most of the broken bark goes to him. The druggist requires the quill or large chip bark; so that the great bulk of the branch bark is also thrown, at low prices, upon the hands of the manufacturer.

As regards the root barks, no classified description is available. In their structure they correspond very closely to the stem barks of the same variety. They can be readily distinguished from the latter by their less thickness, lighter external and darker inner color, greater softness, and twisted or contorted structure. They occur in short, irregular quills or chips, or sometimes as shavings, and contain very much more dust than any other form. Except partly as regards structure, the descriptions of stem barks will not apply to branch barks of the same variety, for the characteristic markings do not appear in the young condition. The branch bark appears in shavings, to the inner surfaces of many of which more or less wood adheres. If the branches were shaved while yet fresh, these shavings will be more or less rolled up and curled; but if dry before being removed, this rolling and curling will not occur. Shaved bark taken from living trees is thin, soft, and brittle, consisting of the outer bark only. The large quills are of uniform length from the same plantation, but not necessarily so from different plantations or different sections. They are commonly from 2 to 3 feet in length, but some have been marketed having a length of 5 feet. Usually they represent the entire circumference of the stem, but occasionally only half of it. In drying they roll up very tightly from one or both edges, and rarely one will be wholly or partly involved in another. The periderm, with all its markings, remains intact, and no other form so well displays the natural appearances as this. Mossed bark differs from natural stem bark in its great thickness and weight, less breadth of the quills, freedom from lichens, very dark color, and rough, corrugated or

warty surface. The outer bark or cellular portion bears a greater ratio to the inner or fibrous portion than in natural bark. Renewed bark is lighter, both in color and weight, thinner, soft and brittle, and marked by a very peculiar external smoothness, sometimes very marked indeed. In its general appearance it is strikingly like a root bark, except for the relative straightness of its fibres. Like the mossed bark, it is in narrow, only partly rolled quills or bands, and is entirely free from lichens.

As they differ so greatly among themselves in coloration, lichen-growth, degree and form of exfoliation, structure and consequent fracture, there are but few characters which can be combined in a general description of the *Cinchona* barks which we consider. The external color varies from light ashy gray to nearly black, the inner varies less in its shades of yellow-brown and red-brown. All are more or less bitter, and most are astringent, but only *Loxa* bark has a distinctive odor. The fracture is never very long-splintery and never tough. As to structure, the bast fibres are loosely arranged, the radial rows being neither continuous nor very long. The fibres themselves are always unbranched, which distinguishes the true from the false barks, are rather short and obtuse, brittle, and usually easily detached from their bed. Laticiferous ducts and stone-cells may or may not be present. The former become less conspicuous as the bark grows older, so that their relative absence becomes indicative of a stage in which the due proportion of alkaloid should have been acquired.

It may be noted here that by far the greater portion of the alkaloid, particularly quinine, is stored in the outer bark, though that in the inner bark is in a purer state. The latter is not stored in the fibres, but in the cellular tissue between them.

As regards the former classification of barks by color, it referred only in small part to the external color, chiefly to the powder. These colors were never regarded as absolutely characteristic, as the three barks, yellow, red and pale, exhibited gradations by which they mingled at their extremes. Under present conditions, the lines of demarcation have become even more indistinct, and, as a matter of fact, in the market the terms "yellow" and "red" are used with great looseness. It is true that we receive much pure-blooded Yellow Bark, *Ledgeriana* from the East, and *Calisaya* both from there and from South America; but it is also undeniable that much of the bark sold under the several names is of mixed blood, and the typical characters are often greatly obscured. The presence in our market of these mixed forms has made the terms even less valuable than they once were, and dealers cannot be found to agree as to the character of many samples. Nevertheless, the occurrence of the typical forms, and appearance in a hybrid of the blended characters, render it desirable to preserve this classification, and to group the new forms around the types.

YELLOW OR CALISAYA BARK. *CINCHONA FLAVA.*

The U. S. Pharm. (8th Rev.) defines *Cinchona* as follows: "The dried bark of *Cinchona Ledgeriana*, Moens; *Cinchona Calisaya*, Weddell; *Cinchona officinalis*, Linné, and of hybrids of these with other species of *Cinchona* (Fam. *Rubiaceae*). The description is as follows: "In quills or curved pieces of variable size, usually 2 or 3, sometimes 5 Mm. thick; externally gray, rarely brownish-gray, with numerous intersecting transverse and longitudinal fissures, which have nearly vertical sides; the outer bark may be absent, the color externally being then cinnamon-brown; inner surface light cinnamon-brown, finely striate; fracture of the outer bark short and granular, of the inner finely splintery; powder light brown or yellowish-brown; odor slight, aromatic; taste bitter and somewhat astringent." U. S. The bark is scarcely collected in a wild state, but cultivated in all plantations. It is the largest quinine yielder, its amount being 70 to 80 per cent. of the total alkaloids contained in the bark. The var. *Ledgeriana* yields a very valuable hybrid bark with *C. succirubra*. *C. Calisaya* also hybridizes with the latter species.

Description.—Flat or "table" bark, now very little produced. Quills, unless broken for shipment, large and handsome, $1\frac{1}{2}$ to $2\frac{1}{2}$ feet long, single or double, sometimes as much as $2\frac{1}{2}$ inches in diameter, $\frac{1}{2}$ to nearly $\frac{1}{2}$ inch thick. Externally gray to lightly brownish gray, internally light cinnamon-color, the striæ very fine. Powder light yellowish brown. Its lichens are thin and closely adherent, not rendering it shaggy. External markings very characteristic, consisting of a very light longitudinal ridging or none at all, but of numerous transverse and longitudinal fissures or cracks, the presence and arrangement of which constitute the chief characteristic of *Calisaya*. Upon the young stems and branches they do not appear. The first to appear are the usually large primary fissures, which encircle the stem at the nodes, or points where pairs of leaves once stood. Subsequently, numerous smaller secondary transverse fissures appear upon the internodes, and these quickly become connected and crossed by longitudinal cracks, thus dividing the periderm up into more or less quadrangular checks, which may remain attached or fall away. This gives to mature *Calisaya* bark an appearance of scalliness like that upon the tarsus of a fowl, and this is known to the South American collectors by a term which signifies the "chicken-leg appearance." It has also been spoken of as a "carving-like" marking. Like the roughness upon a musk-melon, its great development is regarded as an indication of high quality, and especially is this true of a close proximity of the primary fissures. This roughness is also regarded as a sure indication of maturity. There are excellent distinctions between these and the somewhat similar fissures upon the bark of *C. officinalis*. In the latter they are coarser and more gaping. Even more important is the

absence from Pale Bark of most of the longitudinal cracks, so that it does not become "chicken-legged," or at most only very slightly so. The external color of Yellow Bark is lighter than that of the Pale Bark. Longitudinal ridges are few if any, short, irregular, and inconspicuous. In fine South American bark some very small bright-red spots can be detected upon the periderm. East Indian Calisaya can commonly be recognized by its somewhat dingy or brownish shade of gray, the gray of the South American bark being bright and somewhat bluish-steel-colored.

In structure, the zone of large, rather numerous laticiferous ducts just outside the bast is conspicuous in young, and therefore inferior, samples. The rather small bast fibres are loosely scattered, almost uniformly single or radial arrangement being made out. The fracture is rough-splintery, though not coarse. Stone cells few or none. Odorless, more bitter, and less astringent than the Pale Bark. Ledger bark is the same as Calisaya in all its essential characters, but does not reach so great a size. In hybrids of Calisaya with *Succirubra* the characters and quality of the latter appear to predominate.¹

RED BARK. CINCHONA RUBRA.

This bark is recognized by the U. S. and Br. Pharmacopœias (for definition see page 338). It is described in the U. S. P. (8th Rev.) as "in quills or curved pieces of variable size, the bark 2 to 5 Mm. thick; externally gray or grayish-brown, more or less rough from longitudinal rows of warts, or from warty ridges which are sometimes fissured, the transverse fissures rarely numerous or much intersected, and having their sides sloping; inner surface reddish or orange-brown, distinctly striate; fracture short and granular in the outer, shortly and rather coarsely splintery in the inner bark; slightly odorous; taste bitter and astringent; powder reddish-brown." U. S. In the British Pharmacopœia it is described as "imported in quilled or more or less incurved pieces, coated with the periderm, and varying in length from two inches to a foot (five to thirty centimetres) or more—the bark itself from about one-tenth to a quarter of an inch (two and a half to six millimetres) thick, or rarely more; outer surface brownish or reddish brown in color, more or less rough from longitudinal ridges which are most apparent in the branch bark, with numerous warts often running into lines in the larger pieces; in some varieties marked with numerous transverse cracks which have not thickened edges; inner surface brick-red or deep reddish brown, irregularly and coarsely striated; fracture shortly fibrous in the smaller, and finely fibrous in the larger, pieces; powder brownish or reddish brown; no marked odor; taste bitter and somewhat astringent." Br.

It is scarcely collected in a wild state, but cultivated in all plantations except those of South America. Demand and production rapidly decreasing. A large alkaloid yield, but of this only about 20 per cent. is quinine. Largely hybridized with *C. officinalis*. Also hybridized with *C. Calisaya* and its var. *Ledgeriana*.

Description.—Quills similar to those of Calisaya, though running somewhat broader and thicker. Externally of a dingy brown gray, less lichen-bearing than either of the others. Inner surface of a more reddish cinnamon-brown than in Calisaya. Powder reddish brown. The important characteristic of red bark is the prominent longitudinal ridges, many of them short and confluent, with intervening furrows or elongated meshes. The ridges are suberous, bear numerous small warty protuberances, and may be traversed by faint cracks. Transverse fissures may or may not be present in red bark. If so, they are few, short, and irregularly disposed, and not connected by longitudinal cracks to give the checkered appearance of Calisaya. Hybrids with "officinalis" display numerous transverse fissures, and the external color is lighter and more dingy. Fracture short-splintery, not coarse. Odor none. Taste bitter and astringent.

PALE BARK.

Varieties and Synonyms.—Crown Bark, Loxa or Loja Bark, Cuenca Bark, Huanuco Bark. Derived from *C. officinalis*. Collected in a wild state about Loxa and other parts of Ecuador, and cultivated in all plantations except the South American, especially in India. Demand and production decreasing. Quinine constitutes 60 to 70 per cent. of the total alkaloids. Largely hybridized with *C. succirubra*.

Description.—Quills single or double, irregularly broken or entire, 3 or 4 to 15 or 18 inches long by $\frac{1}{4}$ to $\frac{3}{4}$, rarely 1 inch in diameter, and having a very wide range in thickness, the natural mostly 1 to 2 lines thick. Shaggy, with more abundant lichens than in any other species, the abundance of these having been considered, not entirely without reason, as an indication of the relative quality. Color of periderm darker than in the other species, but varying much from a brown gray to nearly black. Inner surface of a paler brown than in the other species, finely striate. Powder pale brown. The external markings consist of transverse fissures and longitudinal ridges, some of them wart-bearing. It is only in the thinner samples, in which the warts and fissures scarcely appear, that the ridges are continuous and conspicuous. In the prominence and breadth of its fissures and the inconspicuousness of its ridges, this bark is most distinct from the Red Bark. These characters are yet sufficiently distinct from the somewhat similar ones of Calisaya, as noted in describing that bark.

Fracture short, the inner fibrous zone sharp and narrow. Taste not so bitter as in the others. Odor of the genuine Loxa variety peculiar and

¹ For the anatomy of the cinchona barks of Java, see Gottfried Meyer, *Zeitschr. f. Naturwissensch.*, Bd. 72.

characteristic. Its structure shows the rather short and not numerous bast fibres in short interrupted single or double radial rows, and much disposed to occur in bundles of three to six or more. Stone cells rarely seen, and laticiferous ducts conspicuous only when young.

HARD YELLOW, OR MARACAIBO BARK.
PUERTO CABELLO BARK.

Derivation not at all certain. Collected only in a wild state in the mountains of Southern Colombia, and yielding almost the whole of the inferior wild bark now collected for market. Importation and sale in the United States quite irregular and unimportant. One of the best of the lower-grade barks, but not to be compared with any of those already described. Said to yield about 2 per cent. of crystallizable sulphates, three-fourths of which is quinine sulphate, but a characteristic specimen assayed for this investigation by Virgil Coblenz yielded 2.65 per cent. of total alkaloids, only a trace of which was quinine. Contains a large amount of resin. The common or commercial names by which have been designated the several barks of the northern countries related to this one are of very irregular application. At the time when the trade in them was large and important, the term "Maracaibo Bark" was restricted to the less resinous variety, derived from *C. cordifolia*. It was also formerly sold simply as "Yellow Bark," and it is not impossible that it was sometimes accepted, under this synonym, for *Calisaya*.¹

1 FALSE BARKS.—In the sixteenth edition of the U. S. Dispensatory may be found an elaborate description of the various false barks which have from time to time entered commerce. Most of this we omit, but the so-called Cuprea Barks at one time were of so much importance that we here insert the matter contained in that edition concerning them. It may be stated, however, that no considerable collection of these barks has been made for some years, and that it does not seem probable that they will again enter commerce. Some fifteen hundred tons of them were said, however, to be stored in London in 1890, the remnant of a much larger quantity of the barks which has been and still is being slowly sold off for unprofessional uses.

cessional uses.

CUPREA BARK.—As early as 1820, a Brazilian surgeon, by the name of Remijlo, pointed out to his countrymen that the bark of certain small trees or shrubs growing in Brazil was as effective as the Peruvian bark in malarial fevers, and ever since in Brazil these plants have been known by the name of *Quintá de Sera*, or *Quintá de Remijlo*. St. Hilaire (*Plantes Us. Bras.*) placed these shrubs in the genus *Cinchona*, as *C. Remijana*, *ferruginea*, and *Vellozti*; but De Candolle (*Prodrum*, 1825, 357) erected for them a new genus, *Remijia*, which has since been universally recognized by botanists. It is distinguished from *Cinchona* by the fruit capsules opening semi-loculicidally, by its petlate seeds, and by its inflorescence in elongated axillary racemes with opposite fascicles of flowers. In 1857 Cuprea bark appeared in the London market. After its value became known, the search for it in South America became very active; indeed, in Colombia a "fever" is said to have broken out, which caused agriculture to be neglected and deranged the business of the country, while in London the supply was so great as to break the whole cinchona market. S. G. Rosengarten informed us that the bark reached this country from London, and also directly from Colombia. There are two distinct regions which yield it: one is the lower part of the basin of the Magdalena River, in the province of Santander, the trees growing in the mountain chain of La Paz, and the port of export being Bucaramanga; the other the basin of the Orinoco, among the mountains which constitute the eastern branch of the Cordillera of the Andes.

Description.—Rusby described it as occurring in irregular broken pieces, rarely so short as an inch, and mostly from 2 to 5 or 6 inches long, 1 to 2½ or 3 inches broad, and ¼ to ⅜ of an inch thick. Formerly it included many much smaller fragments as well as much dust, but these portions are now mostly sifted and winnowed out before marketing. The pieces are more or less flat, the thinner and narrower ones somewhat incurved, the broader and thicker recurved. The bark is compact, heavy, and fibrous. Most of the pieces display upon the outer surface more or less of the periderm, forming silvery-white or yellowish-white patches, very thin and rather soft. Occasionally the periderm is instead dark, hard, very rough, and much fissured. From many pieces the entire periderm is absent, disclosing the outer face of the bast, very similar to the inner face. This is compactly and rather finely fibrous, of a deep yellow, with a slight rust-brown tinge. Throughout, the bast is of this structure and color. Between it and the periderm there may be seen with varying distinctness, in most pieces, a characteristic resinous band of irregular width, dark reddish brown and waxy-lustrous on the

Bentham states that the genus *Remijna* comprises 13 species; according to the researches of José Triana, but two of these, *R. purdieana* Wedd. (*Ann. Sci. Nat.*, 3, 2, 272) and *R. pedunculata*, Triana (*Cinchona pedunculata*, Karsten), yield the Cuprea bark of commerce. (P. J., April, 1882.) An exceedingly important fact connected with these trees is that they grow in a dry climate, and in positions a little above the level of the sea, and hence without doubt could be cultivated in many intertropical countries where the Cinchonas will not grow. They would in all probability flourish within the limits of the United States.

United States.

The specimens of Cuprea bark which have been furnished us as typical by Rosegarten are composed of pieces varying from a half an inch to 3 or 4 inches in length, from a quarter to a twelfth of an inch in thickness, strong and hard, varying from a yellowish to a red cinnamon color, and having a somewhat ruscous tint, distinctly curled, *very smooth* upon their inner surface, on their outer surface smoothish, or in the larger specimens rough, with the epidermis usually adherent; marked, except in the very large pieces, with fine wrinkles, and sometimes with transverse or spiral grooves, which are sometimes quite shallow, but often are deeply and sharply cut. The texture is dense and hard, the fracture is short, not fibrous, and free from spicules. The microscopic characters differ from those of the true Cinchonas in the bast cells being small and with their cavity widely open, not obliterated by secondary layers. The shaved transverse section of Cuprea bark is further characterized by a peculiar horny appearance different from that of the true Cinchonas. The bark is also remarkable for its density, which Arnaud gives as from 1.128 to 1.18, and consequently sinks in water. Cuprea bark varies in the percentage of quinine which it contains. Rosegarten states that the yield in their laboratories has been from 1 to 2 per cent., and that usually the bark is remarkably free from inferior alkaloids. The complete absence of cinchonidine is said to be characteristic of them. D. Howard and I. Hodgkin, B. H. Paul and C. Cowley and T. G. Whiffen almost simultaneously announced the discovery of a new alkaloid, *homocinchonine* or *ultraquinine*, which there is some reason for believing is a combination of quinine and quaidine. (*Chem. News*, xlv. 6.) The characteristic alkaloid is *cinchonamine*, $C_{21}H_{22}N_2O_8$, which occurs in colorless crystals, freely soluble in alcohol and chloroform, and fusing at 184° to 185° C. According to the experiments of W. Ellram, it is a feeble protoplasmic poison in cold blooded animals, producing paralysis of the nerves and muscles without preliminary irritation. In the warm blooded animals it produces epileptic convulsions by irritation of the cerebral cortex.

cut surface. The radial rows of bast fibres are irregular. The fracture is long-fibrous. The odor is distinct, and the taste quite bitter.

Chemical History.

In the analysis of Cinchona bark, the attention of chemists was at first directed exclusively to the action of water and alcohol upon it, and to the determination of the relative proportions of its gummy or extractive and resinous matter. The presence of tannin and of various alkaline or earthy salts in minute quantities was afterwards demonstrated. Fourcroy made an elaborate analysis, which proved the existence of other principles in the bark besides those previously ascertained. Westring was the first who attempted the discovery of an active principle in the bark, on which its febrifuge virtues might depend; but he was not successful. Seguin afterwards pursued the same track, and endeavored, by observing the effects of various reagents, to discover the relative value of different varieties of the drug; but his conclusions have not been supported by subsequent experiment. Deschamps, an apothecary of Lyons, obtained from bark a crystallizable salt of lime, the acid of which Vauquelin afterwards separated, and called *kinic acid* (*quinic acid*). The latter chemist also pushed to a much greater extent the researches of Seguin as to the influence of reagents, and arrived at the conclusion that those barks were most efficient which gave precipitates with tannin or the infusion of galls. Ruess of Moscow, succeeded in isolating a peculiar coloring matter from red bark, which he designated by the name of *cinchonic red*, and obtained a bitter substance which probably consisted in part of the peculiar alkaline principles subsequently discovered. The first step, however, towards the discovery of cinchonine and quinine appears to have been taken by Duncan of Edinburgh, so early as 1803. He believed the precipitate afforded by the infusion of cinchona with that of galls to be a peculiar vegetable principle, and accordingly denominated it *cinchonin*. Gomez, a Portuguese physician, convinced that the active principle of bark resided in this cinchonin, but mixed with impurities, instituted experiments upon some pale bark, which resulted in the separation of a white crystalline substance, considered by him to be the pure *cinchonin* of Duncan. It was obtained by the action of potassium hydroxide upon an aqueous infusion of the alcoholic extract of the bark, and was undoubtedly the principle now universally known by the name of *cinchonine* or *cinchonia*. But Gomez was ignorant of its precise nature, considering it to be analogous to resin. Laubert afterwards obtained the same principle by a different process, and described it under the name of *white matter*, or *pure white resin*. To Pelletier and Caventou was reserved the honor of crowning all these experiments, and applying the results which they obtained to important practical pur-

poses. In 1820 they demonstrated the alkaline character of the principle discovered by Gomez and Laubert, and gave it definitively the name of *cinchonine*. They discovered in the yellow or Calisaya bark another alkaline principle, which they denominated *quinine*. Both these bases they proved to exist in the barks, combined with *quinic* or *kinic acid*, in the state of *cinchonine* and *quinine quinate*. It was, moreover, established by their labors that the febrifuge property of bark depends upon the presence of these two principles. In 1833, O. Henry and Delondre discovered a new alkaloid, but afterwards, finding its composition in its anhydrous state the same as that of quinine, concluded that it was a hydrate of that base. About 1844, Winckler announced anew the existence of the same principle, which he considered distinct, and named *chinidine*, and, under the similar title of *quinidine*, it has now taken its place among the cinchona alkaloids. In 1853, Pasteur found that what had been considered as quinine consisted in fact of two alkaloids, for one of which he retained the name of quinine, and called the other *cinchonidine*, and, on pushing his investigations further, he ascertained that no less than six alkaloids may be obtained from different varieties of Peruvian bark,—namely, *quinine* and *quinidine* isomeric with each other, *cinchonine* and *cinchonidine* also isomeric, and two others, derivatives from the preceding through the agency of heat, viz., *quimicine* from quinine, and *cinchonicine* from cinchonine, each being isomeric with the alkaloid from which it is derived.

The table (page 351) of the natural Cinchona bases is given by A. H. Allen on the authority of Paul and Cownley. In it the alkaloids are arranged according to formulas.

Besides these natural bases we have a number of alkaloids formed by the alteration or treatment of these natural bases, or in some cases molecular compounds of two of the natural bases. They will be noted later in the description of individual bases.

Chinoidine or *Quinoidine* is a term now applied to the resinous substance consisting not only of the *amorphous* natural alkaloids, but of those which are produced artificially through the action of the heat and acids upon the crystalline alkaloids. It was formerly official, but was dropped at the 1890 revision. The following list of bases from Cinchona or allied sources is arranged alphabetically.

APOQUINAMINE. See *Homocinchonine*.

ARICINE, $C_{22}H_{26}N_2O_4$. *Cinchovatine*.—This alkaloid, found in cuseco bark, and quite recently in Cuprea bark, was formerly believed by Hesse to be identical with cinchonidine. Pelletier and Corriol obtained *aricine* as far back as 1829 (see note, p. 308, 14th ed. U. S. D.). Its separate existence is now not doubted. It crystallizes in prisms, and its salts are of sparing solubility.

CHATRAMIDINE, $C_{22}H_{26}N_2O_4 + H_2O$, is an alkaloid obtained from *Remijia Purdieana*.

CHAIRAMINE, $C_{22}H_{26}N_2O_4$, discovered by Hesse in *Remijia Purdieana*, occurs in white needles which are readily soluble in ether and chloroform. (*Ann. Ch. Ph.*, 225, p. 211.)

CINCHAMIDINE, $C_{19}H_{24}N_2O$, is identical with hydrocinchonidine.

CINCHONAMINE, $C_{19}H_{24}N_2O$.—This alkaloid was discovered in 1881 by Arnaud in *Remijia Purdieana* (false cuprea bark). It exists in the proportion of 0.2 per cent., and is usually associated with cinchonine. His process is to treat the bark with milk of lime, dry the mixture, exhaust with boiling alcohol, distil off the alcohol, and take up the residue with diluted hydrochloric acid; cinchonamine hydrochloride crystallizes out, cinchonine hydrochloride remaining in solution. Cinchonamine is insoluble in cold water, soluble in 30 parts of alcohol, more soluble in hot alcohol, and in 100 parts of ether. It is dextrogyrate. For formulas for salts of cinchonamine, see *A. J. P.*, 1884, 156. Physiologically, cinchonamine, according to the experiments of Sée and Bochefontaine, has six times the toxic power of quinine, and has decided sialagogue properties. (*P. J.*, 1885, 791.)

CINCHONICINE, $C_{19}H_{22}N_2O$, being a derivative of cinchonine will be treated elsewhere. (See Index.)

CINCHONIDINE, $C_{19}H_{22}N_2O$.—This alkaloid is treated under the head of its sulphate, which is official in both the U. S. and Br. Pharmacopœias.

CINCHONINE, $C_{19}H_{22}N_2O$, was dismissed from the U. S. (8th Rev.) but its sulphate has been retained and a description of it will be found on page 362.

CINCHOTINE, $C_{19}H_{24}N_2O$ is isomeric with cinchonamine and hydrocinchonine; it dissolves very sparingly in ether.

CONCHAIRAMIDINE, $C_{22}H_{26}N_2O_4 + H_2O$, crystallizes in white needles, and is very soluble in ether, chloroform, alcohol, benzene and acetone. (*Ann. Ch. Ph.*, 225, p. 211.)

CONCHAIRAMINE, $C_{22}H_{26}N_2O_4 + H_2O + C_2H_5O$, also discovered by Hesse, crystallizes with both water and alcohol of crystallization. It is soluble in hot alcohol, ether, and chloroform. The alcoholate dissolves in sulphuric acid containing molybdic acid, giving a brown coloration, which soon becomes intensely green. (*Ann. Ch. Ph.*, 225, p. 211.)

CONCUSONINE, $C_{23}H_{26}N_2O_4$, discovered by Hesse, occurs in the barks of *Remijia*. It is tasteless.

CONQUINAMINE, $C_{19}H_{24}N_2O_2$, occurs with quinamine. According to Allen, it is easily soluble in ether, chloroform and benzene and closely resembles quinamine.

CUPREINE, $C_{19}H_{22}N_2O_2$, was discovered by Paul and Cownley in the bark of *Cinchona cuprea*, or *Remijia pedunculata*, on the upper Orinoco. It crystallizes from alcohol in anhydrous form, but from ether in prisms with $2H_2O$. Cupreine is sparingly soluble in ether or chloroform, but readily soluble in alcohol.

Alkaloid.	Formula.	Melting Point, °C.	Optical Rotation, SD_1^1	Chief Source.
I. Cinchonine Class:				
Paricine	$C_{16}H_{18}N_2O$	130	0	<i>C. lutea</i> and <i>C. succirubra</i> from Darjeeling.
Cinchotine		277	+	Crude cinchonine sulphate.
Cinchonamine		194	+121.1	<i>Remijia Purdieana</i> .
Hydrocinchonine	$C_{19}H_{24}N_2O$	256	..	<i>C. cuprea</i> .
Hydrocinchonidine, (Cinchamidine),		229	-98.4	Mother liquors of homocinchonidine.
Cinchonine		255	+226.5	Various species of <i>cinchona</i> . Almost always present.
Cinchonidine		202	-70	Especially <i>C. rubra</i> .
Homocinchonidine	$C_{19}H_{22}N_2O$	207	-107	With cinchonidine.
Cinchonine		50	+20.1	By heating cinchonine.
Paytine		156	-49.5	From white bark of Payta.
Paytamino	$C_{21}H_{24}N_2O$	..	..	
II. Quinamine Class:				
Quinamine	$C_{19}H_{24}N_2O_2$	172	+104.5	<i>C. succirubra</i> from British India and Java.
Conquinamine		121	+204.6	<i>C. officinalis</i> , <i>C. Calisaya</i> .
Javanine		198	-175.3	<i>C. Calisaya</i> from Java.
Cupreine	$C_{19}H_{22}N_2O_2$	..	..	<i>C. cuprea</i> or <i>Remijia pedunculata</i> .
III. Quinine Class:				
Hydroquinine	$C_{20}H_{28}N_2O_2$	168	-142.2	In mother liquors from quinine sulphate.
Hydroquinidine		166	+	
Quinine		172	-145.2	<i>Calisaya officinalis</i> , etc.
Quinidine	$C_{20}H_{24}N_2O_2$	168	+236.8	By heating quinine sulphate.
Quinicine		60	+44	
IV. Cusconine Class:				
Chairamine		233	+100	
Conchairamine		120	+68.4	
Chairamidine	$C_{22}H_{26}N_2O_4$	127	+7.3	
Conchairamidine		114	-60	
Concusconine		144	+40.8	<i>Remijia Purdieana</i> (Cusco or False Cuprea Bark).
Aricine	$C_{23}H_{26}N_2O_4$	183	-58.2	
Cusconine		110	-54.3	
Cusconidine	$C_{23}H_{26}N_2O_4$	..	..	
Cuscamine		218	..	<i>C. Pelletierana</i> .
Cuscinidine		..	..	
V. Ankydro-bases:				
Dichinchonine	$C_{38}H_{44}N_4O_2$	40	+66	<i>C. rosulenta</i> and <i>C. succirubra</i> .
Diquinicine	$C_{40}H_{46}N_4O_2$	..	+	<i>C. rosulenta</i> and "quinoidine."

¹ The values for the specific rotatory power refer to solutions of the free alkaloids in nearly absolute alcohol.

This solution is lævogyrate, alkaline, gives a dark reddish-brown color with ferric chloride, and responds to the thalleioquin test. It forms with sodium hydroxide a definite crystallizable compound containing $C_{19}H_{21}N_2O.Na$, from the solution of which the alkaloid cannot be extracted by ether. This cupreine-soda is important as furnishing a synthesis of quinine, according to the reaction

(See *Cuprea Bark*, p. 349.)

CUSCAMIDINE, obtained from *C. Pelletierana*.

CUSCAMINE, obtained from *C. Pelletierana*.

CUSCONINE is an amorphous alkaloid found in cusco bark, accompanying cusconine.

CUSCONINE, $C_{23}H_{26}N_2O_4.2H_2O$.—This was discovered by Leverköhn. It is a constituent of the cusco bark, *C. pubescens* var. *Pelletierana*, and Hesse has found it in *Cuprea* bark. It is nearly insoluble in water, soluble in 35 parts of ether, more easily in alcohol, very soluble in chloroform. It may be distinguished from other cinchona alkaloids by forming with sulphuric acid a neutral sulphate, which is amorphous, gelatinous, and yellow, and insoluble in an excess of the acid.

DICINCHONICINE, $C_{38}H_{44}N_4O_2$, *dichonchinine* or *apodicinchonine*, is prepared from cinchonine and cinchonidine, and found in commercial chinoidine. It probably exists in bark in an amorphous condition.

DICINCHONINE, $C_{38}H_{44}N_4O_2$, exists in the bark of *C. rosulenta* and *C. succirubra*, and may also be obtained by fractional precipitation from the mixed amorphous alkaloids before melting, but not from commercial chinoidine.

DIHOMOCINCHONINE, $C_{38}H_{44}N_4O_2$, is an amorphous alkaloid obtained from *C. rosulenta*. It is dextrogyrate.

DIQUINICINE, $C_{40}H_{46}N_4O_3$, also termed *diconchinine* and *apodiquinidine*, is one of the chief amorphous alkaloids in commercial chinoidine; its formula indicates its relation to quinine or quinidine. By deducting one molecule of water from a double molecule of either there results diquinicine, thus:

DIQUINIDINE, *dichonchinine* of Hesse, $C_{40}H_{46}N_4O_3$, is found principally in chinoidine which has been obtained from barks containing quinine and quinidine. It is dextrogyrate, produces a fluorescent solution with diluted sulphuric acid, and responds to the thalleioquin reaction.

HOMOCINCHONICINE, is prepared from homocinchonidine just as cinchonicine and quinicine are prepared from cinchonine and quinine.—i.e., by heating their sulphates.

HOMOCINCHONIDINE, $C_{19}H_{22}N_2O$, is also obtained from *C. rosulenta*. It crystallizes in large prisms, and forms a neutral sulphate containing six molecules of water, and may be found in commerce. Its existence is denied by Skraup.

HOMOCINCHONINE, $C_{19}H_{22}N_2O$, *cinchonidine* of Koch, is obtained from the bark of *C. rosulenta*; it is lævogyrate, and crystallizes from its alcoholic solution in large prisms. It has been mistaken for *aricine*. Homocinchonine is isomeric with *apoquinamine*, which is prepared by boiling quinamine or quinamidine with hydrochloric acid for a short time. It is white, amorphous, soluble in ether, alcohol and diluted hydrochloric acid.

HOMOQUININE, $C_{39}H_{46}N_4O_4 + 4H_2O$, was discovered in 1881 simultaneously by D. Howard and J. Hodgkin, B. H. Paul, A. J. Cownley, and T. G. Whiffen (*P. J.*, 1881, p. 497; 1882, p. 905). It was first noticed by Paul and Cownley on account of the readiness with which it crystallized from its ethereal solution, and is now recognized as a molecular compound of quinine and cupreine of the formula $C_{20}H_{24}N_2O_2.C_{19}H_{22}N_2O_2 + 4H_2O$, and can be obtained by precipitating a solution of sodium cupreinate with one of quinine hydrochloride. It can be resolved into its constituent parts by precipitating the solution with solution of sodium hydroxide, when the quinine may be shaken out with ether, while the cupreine remains in the alkaline liquid as sodium cupreinate. It is freely soluble in alcohol and chloroform, sparingly in ether, from which it crystallizes in proportion as it can take up water. (Hesse.) It is also soluble in diluted sulphuric acid, producing fluorescence, and gives with chlorine water and ammonia a green coloration (thalleioquin). The sulphate coincides exactly in properties with quinine sulphate, except in its behavior with ether. Its tartrate closely resembles cinchonidine tartrate. Homoquinine and its salts behave towards polarized light like quinine.

HYDROCINCHONIDINE, $C_{19}H_{24}N_2O$, bears the same relation to cinchonidine that hydroquinine does to quinine. It is found associated with homocinchonidine in commercial cinchonidine. (*A. J. P.*, 1883, p. 20.)

HYDROCINCHONINE, $C_{19}H_{24}N_2O$, discovered by Caventou, is obtained by treating cinchonine with potassium permanganate. It is soluble in 1300 parts of water, more soluble in alcohol and in ether. The statement that it may be found in commercial cinchonine has not been confirmed. Hesse states that it may be found in *Cuprea* bark. It is also called *cinchotine*. Von Arlt has shown that the *pseudocinchonine* of Hesse is identical with hydrocinchonine.

HYDROQUINICINE, $C_{20}H_{26}N_2O_2$, an amorphous alkaloid obtained by fusing dry hydroquinine sulphate.

HYDROQUINIDINE (hydrocnechinine), $C_{20}H_{26}N_2O_2 + 2\frac{1}{2}H_2O$, is found in commercial quinidine and may be separated by potassium permanganate treatment. It is crystalline, dissolving freely in hot alcohol and in chloroform, but less freely in ether. It gives the thalleioquin reaction like quinine. (*P. J.*, 1882, p. 904.)

HYDROQUININE, $C_{20}H_{26}N_2O_2$, was discovered by Hesse in the mother liquors from which quinine sulphate has been crystallized; he after-

wards found it in the commercial quinine salt to the extent of 4 per cent. Quinine cannot be perfectly freed from hydroquinine even by repeated crystallization of the neutral sulphates, but the hydroquinine can be completely separated by converting the alkaloid into the acid sulphate and recrystallizing this from water or alcohol, when the hydroquinine remains in the mother liquor. (Allen.) According to Hesse, it dissolves freely in alcohol and ether, and, according to Allen, also in chloroform, benzene and ammonia water, and gives the thalleioquin reaction with chlorine water and ammonia like quinine. (*P. J.*, 1882, p. 904.)

JAVANINE, obtained by Hesse from *C. Calisaya* var. *javanica*.

PARICINE, $C_{18}H_{18}N_2O$, is found with quinamine in the bark of *C. succirubra* of Darjeeling, and, according to Hesse, it may be separated from all the cinchona alkaloids with which it associates in solution by treating with sodium carbonate, which precipitates paricine first.

PAYTAMINE, $C_{21}H_{24}N_2O$, is an amorphous alkaloid accompanying paytine.

PAYTINE, $C_{21}H_{24}N_2O_2 \cdot H_2O$, was discovered by Hesse in the white Payta bark.

PROTOQUINAMICINE (see *Quinamicine*).

QUINAMICINE is isomeric with quinamidine; it with protoquinamicine is an artificial base, they are both amorphous, and are produced by heating quinamine in contact with diluted sulphuric acid. If the action of sulphuric acid be continued at $120^\circ C.$ ($248^\circ F.$) to $130^\circ C.$ ($266^\circ F.$), an amorphous brownish substance is formed which may be precipitated by sodium carbonate, and is insoluble in ether. Hesse has named this protoquinamicine.

QUINAMIDINE, *Quinidamia* (*Conchinamine* of Hesse), $C_{19}H_{21}N_3O_2$, is found in *C. rosulenta* and *C. succirubra*, and probably exists in other species of red bark. It crystallizes in long, brilliant prisms, which melt at $123^\circ C.$ ($253.4^\circ F.$) A crystalline hydriodic acid has been produced. Its gold salt like that of quinamine soon decomposes. It may be formed in acid solutions of quinamine through decomposition.

QUINAMINE, *Quinamia*, $C_{19}H_{21}N_3O_2$.—Hesse discovered this cinchona alkaloid in the bark of *C. succirubra* from Darjeeling in 1872. He has since found it in all the East Indian succirubra barks, as well as in the barks of *C. nitida*, *C. Calisaya*, var. *Schuhkrafthii*, *C. erythrantha*, *C. erythrodema*, *C. rosulenta*, and *C. Calisaya* (Para bark), and particularly in *C. Ledgeriana*. De Vrij (*L'Union Pharm.*, 1877, p. 204; *N. R.*, 1877, p. 300) published a process for its preparation. It crystallizes in very long, asbestos-like, white prisms, without water of crystallization. It is nearly insoluble in cold water and in solution of potassium or ammonium hydroxides, more easily in boiling water; is readily dissolved by hot alcohol, which deposits it in crystals, and less readily by diluted alcohol. Ether, petroleum benzin, and benzene dissolve it rather easily at ordinary temperature, more readily when boiling hot, and give it up crys-

tallized on cooling and evaporation. In alcoholic solution it has an alkaline reaction. It neutralizes sulphuric and hydrochloric acids, forming with the latter an amorphous salt, but with the former one that crystallizes with difficulty in hexagonal scales and short prisms. Its solution is dextrogyrate. Quinamine is almost tasteless, but its solutions in acids are very bitter. Its sulphuric acid solution unlike that of quinine is not fluorescent. Its reaction with gold chloride is very characteristic, the solution of the chloride producing with it a yellowish-white precipitate, which soon becomes purple, and separates gold, the supernatant liquid assuming a purplish-red and afterwards a brown color. (For other characters, see *A. J. P.*, 1872, p. 302.)

QUINIDINE, $C_{20}H_{24}N_2O_2$, is isomeric with quinine. It was discovered in 1833 by O. Henry and Delondre, but they afterwards concluded that it was quinine hydroxide, as it had the same composition as quinine. Winckler, in 1844, announced anew the existence of the same alkaloid, which he considered distinct, and named it "*chinidine*;" this substance was not pure, and Pasteur, in 1853, proved that it really consisted of two alkaloids, one of which he called *cinchonidine*, and the other *quinidine*. This view is now generally accepted, although Hesse insists on calling quinidine "*conchinine*," but the latter name is used to only a limited extent in Germany, and scarcely at all elsewhere.

Quinidine crystallizes from alcohol with $2\frac{1}{2}H_2O$ in large lustrous monoclinic prisms or needles, efflorescent in the air; from ether, permanent rhombohedra with $2H_2O$ are obtained; from boiling water permanent plates with $1\frac{1}{2}H_2O$. (Hesse.) It effloresces on exposure to the air. It is sublimable by heat without change, and is condensed in a crystalline form. It resembles quinine not only in composition, but also in its chemical relations with chlorine and ammonia, being rendered green by the successive action of those agents. According to Herapath, it resembles it also in causing a fluorescent appearance when dissolved in water, which is not the case with either cinchonine or cinchonidine, or is so, at least, in a much less degree. It differs, however, in its greater facility of crystallization, in its much less solubility in ether, and in its influence on polarized light, quinidine producing deviation to the right, and quinine to the left. De Vrij states, as the result of his observation, that quinidine forms a salt of very difficult solubility with hydriodic acid, and that, consequently, when a solution of potassium iodide is added to a solution of quinidine sulphate a white precipitate is deposited. By this test quinidine may be distinguished from the other cinchona alkaloids, and detected when mixed with them in solution, no other yielding a precipitate with potassium iodide. (See *A. J. P.*, xxix. 233.) Herapath proposes another test to distinguish this alkaloid from quinine. If to a solution

of quinine sulphate in acetic acid, tincture of iodine be added, and the mixture heated and then allowed to cool, a beautiful emerald-green compound is formed, while quinidine sulphate treated in the same way yields a brown precipitate. When the mixture of this alkaloid with cinchonidine is exposed to hot air, the crystals of quinidine effloresce, and may be distinguished from the others by their opaque whiteness. Vreven (*C. D.*, March 5, 1898, 400) states that the crystals yielded by Marmé's reagent (potassium-cadmium iodide) with quinidine are different from those obtained from any of the other cinchona alkaloids. They are seen under the microscope to consist of bundles of fine needle-like crystals quite different from those of quinine, cinchonine, and cinchonidine.

Commercial quinidine, consisting generally of quinidine with a much larger proportion of cinchonidine, and sometimes, there is reason to believe, exclusively, or nearly so, of the latter alkaloid, was carefully examined by H. G. Leers. It readily crystallizes from its alcoholic solution, by spontaneous evaporation, in hard, shining, colorless crystals, which are easily pulverized and yield a snow-white powder. They melt without decomposition or loss of water at 175° C. (347° F.), and on cooling concrete into a grayish-white crystalline mass. At a higher heat they take fire, and burn with an odor resembling that of the volatile oil of bitter almond. Their taste is bitter, but less intensely so than that of quinine. Quinidine is soluble, according to Hesse, in 2000 parts of water at 15° C.; in 750 parts of boiling water; in 26 parts of 80 per cent. alcohol at 20° C.; in 22 parts of ether of sp. gr. 0.729 at 20° C., or in 35 parts of the same at 10° C. (Hesse, 1863); according to Dragendorff, in 76.4 parts of ether at 10° C.; but the solubilities of commercial quinidine vary more or less according to the relative quantities of quinidine proper and cinchonidine contained in it. With the acids it forms salts, most of which are beautifully crystallizable, and much more soluble than those of quinine. There are, as of quinine and cinchonine, two classes of the salts of quinidine, which may be considered either as neutral and acid or as basic and neutral. It differs from quinine by its much slighter solubility in ether. From the aqueous solution of its salts the alkalies and their carbonates and bicarbonates throw down pulverulent precipitates not soluble in an excess of the precipitant. With sodium phosphate, silver nitrate, and mercuric chloride it forms white, with gold trichloride light yellow, and with platinum, orange-yellow precipitates. It may be obtained by first precipitating it from the solution of one of its salts by an alkali, and then repeatedly dissolving in alcohol and crystallizing, until it is entirely freed from a greenish-yellow resinous substance which is apt to attend it. From quinine it may be separated by repeated washing with ether.

The sulphate of this alkaloid was official in the U. S. P. 1890, and described as follows:

QUINIDINÆ SULPHAS. U. S. 1890, *Quinidine Sulphate*. ($C_{20}H_{24}N_2O_2$) $\cdot$ $2H_2SO_4 \cdot 2H_2O = 780.42$.

"The neutral sulphate of an alkaloid obtained from the bark of several species of *Cinchona* (nat. ord. *Rubiaceæ*). Quinidine Sulphate should be kept in well-stoppered bottles, in a dark place." U. S. 1890.

Quinidine sulphate is, according to one view, neutral, consisting of one molecule each of quinidine, sulphuric acid, and water; according to another, basic, containing two molecules of base, one of acid, and one of water, and therefore a disulphate. It is obtained from the quinidine barks by the same process as that by which quinine sulphate is procured from the quinine-yielding barks. When the two alkaloids are contained in the same bark, the quinidine sulphate (commercial) remains in the mother waters in consequence of its greater solubility. By the addition to its solution of a quantity of sulphuric acid equal to that which it contains, it is converted into the bisulphate (sulphate on the basic view), crystallizable in fine acicular crystals like asbestos, and possessing the formula $C_{20}H_{24}N_2O_2H_2SO_4 + 4H_2O$. Quinidine sulphate was officially described as in "white, silky needles, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 100 parts of water, and in 8 parts of alcohol; in 7 parts of boiling water, and very soluble in boiling alcohol; also in 14 parts of chloroform, and in acidulated water; almost insoluble in ether. When heated to 120° C. (248° F.), the salt loses its water of crystallization (4.6 per cent.). Upon ignition, it is slowly consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. An aqueous solution of the salt, when acidulated with sulphuric acid, has a decided, blue fluorescence. On treating 10 Cc. of an aqueous solution (about 1 in 1600) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or deposit a green precipitate. A cold, saturated aqueous solution of the salt yields a white precipitate with potassium iodide test-solution (difference from *quinine sulphate*). An aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid. Quinidine Sulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). If a small quantity of ammonia water be added to 3 Cc. of an aqueous solution of the salt saturated at 15° C. (59° F.), a white precipitate (quinidine) will be produced, which requires more than 30 Cc. of ammonia or more than 30 times its weight of ether to dissolve it (absence of more than small proportions of *other cinchona alkaloids*)." U. S. 1890.

The action of quinidine sulphate upon the system is similar to that of quinine, but is less powerful in the proportion of three to two.

QUINICINE, $C_{20}H_{24}N_2O_2$, being a derivative of quinine, will be treated under that head.

QUININE, $C_{20}H_{24}N_2O_2 + 3H_2O$.—This alkaloid has been made official, as have its bisulphate, hydrobromide, hydrochloride, salicylate, and sulphate, and they will be treated under separate heads (see Index).

The following additional substances have been found in *Cinchona* bark; *Quinic* or *Kinic*, *Quinovic* or *Kinovic*, *Quinotannic* or *Cinchotannic acids*, *Quinovin* or *Kinovin*, *Cinchonic red*, volatile butyraceous oil, in small quantity, and red and yellow coloring matter. These constituents, arranged alphabetically, will now be considered in detail.

CINCHOCERTIN, $C_{27}H_{48}O_2$.—This substance was discovered by Kerner in flat Calisaya bark from South America. He obtained it in white, very light, crystalline scales. It is not soluble in boiling water, nor in hydrochloric, diluted sulphuric, or glacial acetic acid, but dissolves readily in ether, chloroform, and alcohol. (*A. J. P.*, 1883, p. 357.)

CINCHOFULVIC ACID.—The *cinchonic red* of Reuss, identical with the *insoluble red coloring matter* of Pelletier and Caventou, $C_{12}H_{14}O_7$, is reddish brown, insipid, inodorous, largely soluble in alcohol, especially when hot, and almost insoluble in ether or water, though the latter dissolves a little at the boiling temperature. The acids promote its solubility in water. It precipitates tartar emetic, but not gelatin; but if treated with a cold solution of potassium or sodium hydroxide, or with ammonia, lime, or baryta with heat, and then precipitated by an acid, it acquires the property of forming an insoluble compound with gelatin. It yields protocatechuic acid, $C_7H_6O_4$, when fused with potassium hydroxide. It is most abundant in the red bark (over 10 per cent.), and least so in the pale.

CINCHOTANNIC ACID. *Cinchotannin*, $C_{14}H_{16}O_8$.—*Tannic acid*, *tannin*, or *soluble red coloring matter* of Pelletier and Caventou, has been considered as possessing all the properties which characterize the proximate vegetable principles associated together under the name cinchotannic acid. It is a glucoside existing in *cinchona* barks in the proportion of 3 to 4 per cent. It has a brownish-red color and an austere taste, is soluble in water and alcohol, combines with metallic oxides, and produces precipitates with the salts of iron, which vary in color according to the variety of bark, being deep green with the pale bark, blackish brown with the yellow, and reddish brown with the red. It also forms white precipitates with tartar emetic and gelatin, and readily combines with atmospheric oxygen, becoming insoluble. It must, however, differ materially from the tannic acid of galls, which could not exist in aqueous solutions containing cinchonine and quinine without forming insoluble compounds with them. Rembold has

shown that when cinchotannic acid is boiled with diluted sulphuric acid, cinchonic red is produced, sugar being formed at the same time.

FATTY MATTER.—This was first obtained pure by Laubert, and is of a greenish color as obtained from the pale bark, orange yellow from the yellow. It is insoluble in water, soluble in boiling alcohol, which deposits a part of it on cooling, very soluble in ether, even cold, and saponifiable with the alkalies.

QUINIC ACID (*Hexahydrotetraoxybenzoic acid*), $C_7H_{12}O_6$.—This acid was isolated as early as 1790 by Hofmann, an apothecary of Leer, who obtained it from the calcium salt from *cinchona*. It exists in a number of important plants,—ivy, oak, elm, ash, coffee, etc. It may be desirable to procure the alkaloids in the state of saline combination in which they exist in the bark, since it is possible that they may exert an influence over the system in this state somewhat different from that produced by their combinations with sulphuric or other mineral acids. As it is impossible to procure the quinates immediately from the bark in a pure state, it becomes necessary first to obtain the quinic acid separately, which may thus become of some practical importance. We shall, therefore, briefly describe the mode of procuring it, and its characteristic properties. It is usually prepared from calcium quinate, the residue obtained in the manufacture of quinine sulphate (see *Quinine Sulphas*) by decomposing an aqueous solution of calcium quinate with oxalic acid, filtering out the precipitated calcium oxalate, and evaporating the filtrate to the crystallizing point; or by evaporating the infusion of bark to a solid consistence, and treating the extract with alcohol, we have in the residue a viscid matter consisting chiefly of mucilage with calcium quinate, which is insoluble in alcohol. If an aqueous solution of this substance be formed, and allowed to evaporate at a gentle heat, crystals of the quinate will be deposited, which may be purified by a second crystallization. The salt thus obtained, being dissolved in water, is decomposed by means of oxalic acid, which precipitates the lime and leaves the *quinic acid* in solution. This may be procured in the crystalline state by spontaneous evaporation, though as usually prepared it is in the form of a thick syrupy liquid. The crystals are transparent and colorless, sour to the taste, soluble in 2 parts of water, but less soluble in alcohol, and almost insoluble in ether. By heating quinic acid or a quinate with manganese dioxide and sulphuric acid, we get yellow crystals of *kinone*, better known as *quinone*, $C_6H_4O_2$, a reaction which may be used for ascertaining the presence of quinic acid. The cinchonine and quinine quinates may be obtained either by the direct combination of their constituents, or by the mutual decomposition of the sulphates of those alkaloids and calcium quinate. *Cinchonine quinate* has a bitter and astringent taste, is very soluble in water, is soluble also in alcohol, and is crys-

tallized with difficulty. *Quinine quinate* is also very soluble in water, but less so in rectified alcohol. Its taste is very bitter, resembling that of yellow bark. It crystallizes in beautiful stellate groups, which are opaque or semi-transparent. The salt is with difficulty obtained free from color, and only by employing the ingredients in a state of extreme purity. (*Ann. Ch. Phys.*, Juillet, 1829.) Lautemann found, in experiments upon himself, that quinic acid, when taken into the system, undergoes a conversion into hippuric acid and in this state escapes with the urine. (*Ann. Ch. Ph.*, cxxv. 9.) Rabuteau has investigated the physiological properties of quinic acid, and has found it closely to resemble the ordinary vegetable acids, being harmless in its effects on the system, and forming with water a refreshing drink like lemonade. Like other vegetable acids, also, it is decomposed in the system, forming, when taken in the state of an alkaline salt, a carbonate of the alkali in the blood, and rendering that fluid alkaline. (*A. J. M. S.*, Oct. 1872, p. 524.) Quinic acid is said by Zwenger to have been found in the leaves of *Vaccinium Myrtillus*, L. (*A. J. P.*, March, 1861, p. 128.) Several esters of quinic acid and compounds with synthetic bases have been recently introduced into medicine, viz.—*chinotropin*, *sidonal*, *new sidonal*, *urosin*, and *ural*.

QUINOVIN, *Kinovin*, or *Chinovin*. *Kinovic bitter*, $C_{22}H_{32}O_{11}$.—Originally discovered in the false bark called quinquina nova, or new bark, this substance has since been found in *Calisaya* bark, and probably exists, in greater or less proportion, in all the *Cinchona* barks. It was detected by De Vrij not only in the bark but also in the wood and leaves of *C. Calisaya* and *C. lucumæfolia*. (*J. P. C.*, Avril, 1860, pp. 225, 258.) It is white, uncrystallizable, almost insoluble in water, but readily dissolved by alcohol and ether. It is very bitter, and, as it is asserted to have no febrifuge virtues, may on this account mislead the judgment in relation to the activity of the bark in which it may be found. Some barks are said to owe their bitterness mainly to this ingredient. Winekler gives, as a certain test of its presence in any bark, copper sulphate, which is indifferent to infusion of bark containing none of this principle, but detects the smallest proportion of it by producing a dirty-green color, soon followed by the deposition of a fine similarly colored powder. This is a salt of copper, and has a very bitter and metallic taste. (See *A. J. P.*, xxv. 343.)

Quinovin in alcoholic solution was shown in 1859 by Hlasiwetz to be resolved by means of hydrochloric acid gas into quinic acid, $C_{22}H_{32}O_{11}$, and an uncrystallizable sugar, *mannitan*, $C_6H_{12}O_6$, by assimilation of H_2O . The formation of quinic acid takes place more easily if kinovin is placed in contact with sodium amalgam and spirit of wine, when after 12 hours mannitan and sodium quinate are formed. (*Pharmacographia*, 2d ed., p. 364.)

Liebermann and Giesel (*Ber. d. Chem. Ges.*, xvi. 987) believe that two modifications exist, *α-quinovin* and *β-quinovin*, the former in *Cinchona*, the latter in *Cuprea* bark: *α-quinovin* is a white crystalline powder, nearly insoluble in cold and hot water, but soluble in caustic alkalis, lime water, ammonia water, and glacial acetic acid, soluble with difficulty in chloroform, ether, and petroleum benzin; it dissolves in 57 parts of nearly absolute alcohol. *β-quinovin* closely resembles *α-quinovin*, but is not soluble in ether, and crystallizes readily from diluted alcohol.

De Vrij proposes the following method of isolating quinovin. Macerate powdered cinchona with a very weak solution of potassium or sodium hydroxides, precipitate the filtered liquid with an acid, redissolve the precipitate in milk of lime to separate the cinchonic red, filter and precipitate the solution boiling hot with hydrochloric acid, separate the precipitate, wash it, express as much as possible, and lastly dry it on porous stones, and powder it. For a process for preparing quinovin from by-products, see Allen's *Organic Analysis*, 1892, vol. iii., Part ii., p. 443. Thus prepared, the quinic bitter forms soluble compounds with magnesia and lime, and has been employed, in this mode of combination, as a tonic in the hospital of Batavia, with encouraging success. (*J. P. C.*, Avril, 1860, p. 258.)

QUINOVIC ACID (*Kinovic Acid*).—Resulting from the decomposition of quinovin, and possessing the formula $C_{22}H_{32}O_{11}$; in white, rhomboidal crystals, insoluble in water, but slightly soluble in ether, somewhat more so in boiling alcohol, but very soluble in ammonia and the fixed alkalies, the solutions frothing like soap water. On adding an acid to an alkaline solution of quinic acid, a hydrate of quinic acid is thrown down as a very voluminous jelly, the whole contents of the vessel gelatinizing. Kerner (*Deutsche Klin.*, xx. 81) speaks very favorably of quinic acid as an excellent and at the same time perfectly safe tonic, which produces no narcotic symptoms, and, given to adults in the quantity of half or three-quarters of an ounce, causes not the slightest ill effect. He prefers it in the form of calcium quinate, of which forty grains (2.6 Gm.) is the average dose. (*Am. J. M. S.*, Oct. 1869, 543.)

By the experiments of Henry, Jr., and Plisson, it may be considered as established that the alkaloids of the different varieties of bark are combined at the same time with quinic acid and with one or more of the coloring matters which, in relation to these substances, appear to act the part of acids. This idea was originally suggested by Robiquet. (*J. P. C.*, xii. 282, 369.) The compounds of quinine, cinchonine, etc., with the coloring matter are scarcely soluble in water, while their quinates are very soluble.

The odor of bark appears to depend on a *volatile oil*, which Fabroni and Trommsdorff obtained by distillation with water. The oil

floated on the surface of the water, was of a thick consistence, and had a bitterish, acrid taste, with the odor of bark.

YELLOW COLORING MATTER.—This has little taste, is soluble in water, alcohol, and ether, precipitates neither gelatin nor tartar emetic, and is itself precipitated by lead subacetate.

Incompatibles.—Of the relations of bark to the several solvents employed in pharmacy we shall speak hereafter, under the heads of its tincture and other preparations, where we shall also have an opportunity of mentioning some of the more prominent substances which afford precipitates with its liquid preparations. It is sufficient at present to state that all the substances which precipitate the infusion of bark do not by any means necessarily affect its virtues, as it contains several inert ingredients which form insoluble compounds with bodies that do not disturb its active principles. As *tannic acid* forms with the alkaloids compounds insoluble in water, it is desirable that substances containing this acid in a free state should not be prescribed in connection with the infusion or decoction of bark; for, though these insoluble tannates might be found efficacious if administered, yet, being precipitated from the liquid, they would be likely to be thrown away as dregs, or at any rate would communicate, if agitated, an unpleasant turbidity. The same may be said of the *tincture* and *compound solution of iodine*, which form insoluble compounds with all the cinchona alkaloids, and of the *alkalies*, *alkaline carbonates*, and *alkaline earths*, which precipitate them from their aqueous solution.

Estimation of Value.—It is evident, from what has been said, that an infusion of bark, on account of the tannin-like principle which it contains, may precipitate gelatin, tartar emetic, and the salts of iron, without having a particle of cinchonine, quinine, or other alkaloid in its composition, and that consequently any inference as to its value, drawn from these chemical properties, would be fallacious; but, as the active principles are thrown down by the tannic acid of galls, no bark can be considered good which does not afford a precipitate with the infusion of this substance.¹

It is impossible to determine with accuracy the relative proportion of the active ingredients in the different varieties of cinchona, as the quantity is by no means uniform in different specimens of the same variety. The results of the most recent experiments have been already stated under the head of the several varieties of bark described. But it is highly important, in relation to any particular sample of bark, to be able to ascertain its medicinal efficiency, which is measured by the quantity of the peculiar cinchona alkaloids it may contain. In 1880 the U. S. Pharmacopeia for the first time in its history gave a process for assaying Cinchona bark; this was deemed necessary because of the impossibility of judging of the quality of the bark by its physical appearances. The manufacturing chemist never trusts to anything short of a careful chemical assay, and Cinchona bark should never be dispensed or used without having its quality tested or certified to by a competent authority. The following official process of assay is much simpler than that of the U. S. Pharm. 1880, and will give sufficiently accurate results for the uses of the pharmacist. Each manufacturer and quinologist usually has his own secret process, and a method which will accurately differentiate the quantities of the alkaloids is usually difficult and unreliable in the hands of the inexperienced.

Assay (8th Rev.).—"Cinchona, in No. 80 (or finer) powder, *fifteen grammes*; Ether, sp. gr. not above 0.720 at 25° C. (77° F.); Chloroform, Ammonia Water, Distilled Water, Normal Sulphuric Acid V.S., each, *a sufficient quantity*. Introduce the Cinchona into an Erlenmeyer flask or bottle of about 200 Cc. capacity, and add a mixture of 125 Cc. of ether and 25 Cc. of chloroform; then insert the stopper securely, shake the flask vigorously, and allow it to stand for ten minutes. Then add 10 Cc. of ammonia water, and allow it to stand for five hours, shaking at frequent intervals (or continuously with the aid of a mechanical shaker). Next add 15 Cc. of distilled water, shake the flask vigorously, and allow it to stand for a few minutes, so as to cause the powder to settle readily. When the supernatant fluid is quite clear, decant into a measuring flask or cylinder exactly 100 Cc. of the supernatant liquid (representing 10 Gm. of Cinchona), transfer this to a separator and add 15 Cc. of normal sulphuric acid V.S., or sufficient to make the liquid distinctly acid. Shake the separator vigorously for one minute, and allow the two layers of liquid to separate completely. Draw off the lower aqueous layer into a flask. Then add 5 Cc. of normal sulphuric acid V.S. and 5 Cc. of distilled water to the separator and shake it vigorously for about one minute, allow the liquids to separate as before, and again draw off the lower aqueous layer into the flask. Repeat the operation, using 5 Cc. of distilled water in the separator (without acid), drawing off the aqueous liquid into the

¹ *Grahe's Test.*—A test of the Cinchona barks containing one or more of their characteristic alkaloids has been proposed by Grahe. It is founded on the fact that when these barks are exposed to destructive distillation a product is obtained of a bright carmine color, which is yielded by no other bark under the same circumstances, and not by cinchona unless it contain one or more of its peculiar alkaloids. Nor do the pure alkaloids afford it; but, if mixed with a little acetic, quinic, tannic, citric, or tartaric acid, they exhibit the reaction, showing that in the bark it takes place between the alkaloids and organic acids contained in it. Grahe applies the test by heating a piece of the bark weighing from five to ten grains in an ordinary test-tube, and gradually increasing the heat to redness. Whitish smoke, and aqueous vapor condensing on the surface of the tube, are first given off, which are soon followed by the appearance of redness in the fumes, and by the deposition, an inch above the heated part, of a red pulverulent film, which is gradually changed into a thick, oily liquid, running down the glass in drops or streaks of a fine carmine color. (*Ch. Ob.*, Feb. 17, 1858, p. 97.)

flask. Filter the combined acid liquids into a measuring cylinder, and wash the filter and flask with enough distilled water to make the contents of the cylinder measure exactly 50 Cc. Pour half (25 Cc.) of the acid liquid into a separator marked No. 1, and the remaining half (25 Cc.) into another separator marked No. 2, which set aside.

I. For Anhydrous Cinchona Alkaloids.—To separator No. 1 (see above) add 25 Cc. of a mixture of chloroform 3 volumes and ether 1 volume, also 5 Cc. of ammonia water, or sufficient to render the liquid alkaline. Insert the stopper and shake the separator carefully for one minute, and then draw off the lower layer into a tared flask or beaker. Add 20 Cc. more of the chloroform-ether mixture to the separator, insert the stopper, and shake the liquid carefully for one minute, again drawing off the lower layer into the tared flask. Repeat the operation with 10 Cc. of chloroform, and draw this off into the tared flask. Evaporate the chloroform-ether solutions in the tared flask or beaker slowly and carefully to dryness on a water-bath. Add 3 Cc. of ether to the dry residue, and again evaporate to dryness. Then place the flask or beaker in an air-bath and heat at 110° C. (230° F.) until the weight after cooling remains constant. The weight of the residue in grammes multiplied by 20 will give the percentage of anhydrous cinchona alkaloids (total alkaloids) in the Cinchona.

II. For Ether-Soluble Alkaloids.—To separator No. 2 (see above), containing the other 25 Cc. of acid liquid, add 25 Cc. of ether and 5 Cc. of ammonia water, or sufficient to render the liquid alkaline. The temperature of the liquid should be kept below 20° C. (68° F.), by cooling it, if necessary. Shake the separator moderately for two minutes, and allow the liquid to stand for ten minutes at 15° C. (59° F.); after the liquids have separated, draw off and reject the lower aqueous layer and transfer the ethereal liquid to a tared beaker. Add 5 Cc. more of ether to the separator, rinse carefully, and add the rinsings to the tared beaker. Evaporate the ether carefully by the aid of a water-bath, dry the beaker and contents in an air-bath at 110° (230° F.) for two hours, cool, and weigh. The weight of the residue in grammes multiplied by 20 gives the percentage of the anhydrous ether-soluble alkaloids contained in the Cinchona.

NOTE.—Ether-soluble alkaloids include quinine, quinidine, and cinchonidine." *U. S.*

The British Pharmacopœia gives the following method for the testing of Red Cinchona bark:

Test. "When used for purposes other than that of obtaining the alkaloids or their salts, it should yield between 5 and 6 per cent. of total alkaloids, of which not less than half should consist of quinine and cinchonidine, as estimated by the following methods.

Mix 20 grammes of Red Cinchona Bark, in No. 60 powder, with 6 grammes of calcium

hydroxide; slightly moisten the powders with 20 cubic centimetres of water; mix the whole intimately in a small porcelain dish or mortar; allow the mixture to stand for an hour or two, when it will present the characters of a moist dark brown powder, in which there should be no lumps or visible white particles. Transfer this powder to a suitable flask fitted with a small reflux condenser, add 130 cubic centimetres of benzolated amylic alcohol,¹ boil them together for about half an hour, decant the liquid on to a filter, leaving the powder in the flask; add more of the benzolated amylic alcohol to the powder, and boil and decant as before; repeat this operation a third time, then turn the contents of the flask on to the filter, and wash by percolation with more of the benzolated amylic alcohol until the Bark is exhausted. Introduce the collected filtrate, while still warm, into a stoppered glass separator; add to it 2 cubic centimetres of diluted hydrochloric acid, mixed with 12 cubic centimetres of water; shake them well together, and when the acid liquid has separated this may be drawn off, and the process repeated with water slightly acidulated with hydrochloric acid, until the whole of the alkaloids have been removed. The liquid should then, while warm, be carefully and exactly neutralized with solution of ammonia, and concentrated to the bulk of 16 cubic centimetres. If now about 1.5 grammes of sodium potassium tartrate, dissolved in twice its weight of water, be added to the solution, and the mixture stirred with a glass rod, insoluble tartrates of quinine and cinchonidine will separate completely in about an hour, and these collected on a filter, washed, and dried in a water-oven, will contain eight-tenths of their weight of the alkaloids, quinine and cinchonidine, which, multiplied by 5, gives the weight of those alkaloids present in 100 grammes of the bark. To the mother-liquor from the preceding process add solution of ammonia in slight excess. Collect, wash, and dry the precipitate, which will contain the other alkaloids. The weight of this precipitate, multiplied by 5, and added to the percentage weight of the quinine and cinchonidine, gives the percentage weight of total alkaloids." *Br.*

The German Pharmacopœia gives the following method: "The powdered bark is assayed as follows: Shake 20 Gm. of it strongly and repeatedly with a mixture of 10 Gm. of water of ammonia, 20 Gm. of alcohol, and 170 Gm. of ether, and, after a day, decant 120 Gm. of the clear liquid. To this liquid add 3 Cc. of volumetric hydrochloric acid, remove the ether by distillation or evaporation, and again add, if necessary, enough hydrochloric acid to render the solution acid. Then filter, and mix the cold filtrate with 3.5 Cc. of volumetric solution of potassa. When the alkaloids have subsided, drop more of the solution of potassa

¹ "Made by mixing together three volumes of benzol and one of amylic alcohol, and decanting the supernatant fluid from any deposited water." *Br.*

into the clear supernatant liquid, until nothing more is thrown down. Finally, collect the whole of the precipitate on a filter, and wash it repeatedly with small portions of water, until drops of the wash water allowed to come in contact with the surface of a cold, aqueous, neutral, saturated solution of sulphate of quinine no longer produce a turbidity. When the alkaloids have drained, press them gently between bibulous paper, and, having dried them sufficiently in the air to permit their being removed to a watch-glass, dry them completely, first over sulphuric acid, and, finally, by means of a water-bath. The weight of alkaloids procured by this method should not be less than 0.42 Gm. When a small portion of the same is boiled with 300 parts of water, the filtrate, after cooling, should yield flakes of quinine. When to 5 parts of this solution, after being cooled and decanted, 1 part of chlorine water is added, and water of ammonia immediately dropped in, the liquid should acquire a beautiful green color." *P. G.* For E. R. Squibb's method of assay see U. S. D., 18th ed., p. 412.

It is usually sufficient to ascertain the quantity of total alkaloids in bark, for this is really a test of the efficacy of the bark for pharmaceutical purposes, since all the organic alkaline principles contained in it are efficient as medicines, and in all probability in a nearly equal degree. But for manufacturing purposes it is necessary to push the investigation further, and ascertain the proportion of the several alkaloids in the mixture.

De Vrij obtained from bark of *C. officinalis* grown at Ootacamund total alkaloids as high as 11.96 per cent. (9.1 per cent. of which was quinine). The highest yield yet recorded was obtained by De Vrij from Ootacamund bark, 13.5 per cent., the great part of which was quinine.¹ Between these and the barks of

¹ *Quinetum*.—Under this name a compound is produced in India and other Eastern countries, which consists of the mixed alkaloids of Red Bark, the object being to produce a cheap febrifuge which will answer all practical purposes and save the cost of refining. De Vrij named it *quinetum quinotannicum* and considered it to be a mixture of the quinotannates of the mixed crude alkaloids. The following formula was adopted by the Dutch Society for the Advancement of Pharmacy: "Red Cinchona bark (the bark of the trunk of *Cinchona succirubra*, grown in Java and India, and containing at least 6 per cent. of alkaloids), in fine powder, 1000 parts; normal hydrochloric acid (volumetric standard), 1000 parts; oxalic acid, 12 parts; solution of soda, q. s.; water, q. s.

Macerate the cinchona with the hydrochloric acid and 3000 parts of water for at least 12 hours, occasionally stirring. Pour the mixture into a percolator, the lower orifice of which is closed by a linen plug, and, as soon as the liquid runs off clear, displace with water until the liquid running from the percolator is no longer precipitated (though it may be colored) by solution of soda.

To the strained liquid (which may amount to perhaps 8000 parts) add the oxalic acid dissolved in a little water, and then add *carefully*, under continued stirring, just enough solution of soda until the precipitate which forms at first separates in coherent flakes. Separate this precipitate (which consists of calcium oxalate and cinchona red) by pouring off as much of the still acid clear liquid as is possible, and filter the remainder. To the united liquids add now an excess of solution of soda, let it settle, and collect the precipitate upon a moistened double filter. Wash it with a weak soda solution until the washings have only a light-red color; then wash with the least pos-

lowest value there is every grade of productiveness, down to a mere trace of alkaloidal matter.

The quantities of cinchona and other barks used in the manufacture of quinine imported into the United States during the year 1903 was 3,980,072 lbs, valued at \$547,332, and for 1904 3,605,131 lbs., valued at \$501,375. In the same years the importations of sulphate of quinine amounted to 2,534,106 oz., valued at \$576,404, and 3,059,514 oz., valued at \$659,868.

Uses.—This valuable remedy was unknown to the civilized world until about the middle of the seventeenth century, though the natives of Peru are generally supposed to have been long previously acquainted with its febrifuge powers. Humboldt, however, is of a different opinion. In his memoir on the Cinchona forests, he states that it is unknown as a remedy to the Indians inhabiting the country where it grows, and, as these people adhere pertinaciously to the habits of their ancestors, he concludes that it never was employed by them. They have generally the most violent prejudices against it, considering it poisonous, and in the treatment of fever prefer the milder indigenous remedies. Ruiz and Pavon, however, ascribe the discovery to the Indians; and Tschudi states, in his "*Travels in Peru*" (Am. ed., ii. 280), that the inhabitants of the Peruvian forests drink an infusion of the green bark as a remedy in intermittent fever. On the other hand, the statements of Humboldt have been confirmed by the travellers Markham and Spence, the former remarking that the native Indian doctors do not use the bark, and the latter that the Cascarilleros of Ecuador believe that their red bark is used solely for dyeing. It is uncertain whether, as Jussieu stated in 1739, the Jesuit fathers received their knowledge from the Indians, or, as Humboldt believes, discovered the virtues of the drug for themselves, having been led to make trial of it by its extreme bitterness. The Countess Chinchon, wife of the Viceroy of Peru, having in her own person experienced the beneficial effects of the bark is said, on her return to Spain in the year 1640, to have first introduced the remedy into Europe. Hence the name of *pulvis Comitissæ*, by which it was first known. After its introduction it was distributed and sold

sible quantity of water, until the washings begin to have a bitter taste. Let the precipitate drain, dry it in the air, and powder it.

Quinetum is completely soluble in strong, warm alcohol. When 3.1 grammes of *quinetum* are dissolved in 10 Cc. of normal hydrochloric acid, this solution must be clear, and, on the addition of 2 grammes of Rochelle salt, must yield a precipitate which, when dried, should amount to at least 65 per cent. of the weight of the *quinetum* dissolved." (*N. R.*, 1882, p. 10.)

Febrifuge.—Under this name, the British Indian government has introduced a manufactured product, designed to furnish a cheap but valuable substitute for quinine sulphate. It is largely produced at Sikim, India, by a modification of Dubreuil's process, which consists in extracting the powdered mixed barks with hydrochloric acid, precipitating the alkaloids by the addition of solution of sodium hydroxide, and shaking out with petroleum, adding to the petroleum solution a calculated quantity of diluted sulphuric acid, evaporating and crystallizing.

by the Jesuits, who are said to have obtained for it the price of its weight in silver. From this circumstance it was called *Jesuits' powder*, a title which it long retained. In 1653, Chifflet, physician to the Archduke Leopold, directed the attention of all Europe to the bark by his work entitled *Pulvis Febrifugus Orbis Americani*. This gave rise to a very active controversy, the high price of the drug aiding very greatly those who opposed its introduction. According to Sturm, twenty doses in 1658 cost sixty florins. It seems first to have been advertised in England for sale in 1658 by a James Thomson, and by 1660 it was much employed. It still, however, encountered much prejudice and ignorance, and was not made official in the London Pharmacopœia until 1677. Sir Robert Talbot (or Talbor) used it as a secret remedy with so much address and success that in 1679 he cured Charles II. of a tertian, and subsequently sold his secret to Louis XIV. of France, who published it in 1681.

When taken into the stomach, the bark usually excites in a short time a sense of warmth in the epigastrium, which often diffuses itself over the abdomen and even the breast, and is sometimes attended with considerable gastric and intestinal irritation. Nausea and vomiting are sometimes produced, especially if the stomach was previously in an inflamed or irritated state; and its action is not unfrequently accompanied by purging. If the dose of the cinchona bark has been large enough, the symptoms of cinchonism may result. (See *Quinina*.) At one time cinchona bark and its preparations were used as antiperiodics, but at present for such purpose one of its alkaloids is always selected. The best preparation for use as a tonic is the compound tincture.

Dose, ten grains to one drachm (0.65 to 3.9 Gm.).

CINCHONIDINÆ SULPHAS. U. S.

CINCHONIDINE SULPHATE

(cîn-phô-nî-dî-næ sül'phäs)

"The neutral sulphate $[\text{SO}_2(\text{OH})_2 \cdot (\text{C}_{19}\text{H}_{22}\text{N}_2\text{O})_2 + 3\text{H}_2\text{O}]$ of an alkaloid obtained from the bark of several species of *Cinchona*." *U. S.*

Cinchonidinum sulfuricum; Sulphate of Cinchonidine; Schwefelsaures Cinchonidin, Cinchonidinsulfat, *G.*; Sulfate de Cinchonidine basique, *Fr.*; Solfato di cinchonidina, *It.*

This salt is prepared from the mother liquors obtained in the manufacture of quinine sulphate, and is separated from the sulphates of the other alkaloids by fractional crystallization. The British-India and Javanese cultivated red

barks usually contain large quantities of cinchonidine. Of the South American barks, probably the Colombian varieties yield the largest proportion of cinchonidine. Owing to some confusion in naming cinchonidine and quinidine, this alkaloid is sometimes incorrectly called in Germany *chinidine*. Skraup's researches on the composition of cinchonine and cinchonidine (1879) established the correctness of the formula $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O}$, instead of the long-accepted formula of Pasteur (1853), $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}$. Skraup's formula has been confirmed by Hesse, and is generally accepted by chemists.

Properties.—Cinchonidine sulphate occurs in "white, glistening, silky needles or prisms, permanent in the air, odorless, having a very bitter taste. When crystallized from dilute solutions, it contains six molecules of water of crystallization, and when from concentrated solutions, three molecules. Soluble in 63 parts of water, 72 parts of alcohol, 4400 parts of ether, and in 900 parts of chloroform at 25° C. (77° F.); soluble in 21 parts of water at 80° C. (176° F.), and in 32 parts of alcohol at 60° C. (140° F.). When heated to 100° C. (212° F.), the salt loses its water of crystallization, and at 203° C. (397.4° F.), it darkens, and then melts at 205.3° C. (401.5° F.). At a higher temperature it ignites and is consumed without leaving a residue. The aqueous solution is neutral or only faintly alkaline to phenolphthalein T.S. or litmus T.S., and is lævogyrate. Its aqueous solution yields with barium chloride T.S. a white precipitate, insoluble in hydrochloric acid. On adding ammonia water to the aqueous solution of the salt, a white precipitate (cinchonidine) is produced, which is but slightly soluble in ammonia, but which, when freshly precipitated, dissolves in 10 parts of ether, the greater part afterwards separating in crystals. If sulphuric acid be added to a small quantity of the salt, not more than a faintly yellowish color should be developed (limit of readily carbonizable organic impurities). Upon adding to this liquid a crystal of potassium dichromate, a yellowish-green color is produced, which gradually changes to grass-green. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.920 Gm. (absence of an undue amount of water). A solution of the salt (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of quinine or quinidine sulphates). If 0.5 Gm. of the salt be macerated, with frequent agitation, at the ordinary temperature, with 20 Cc. of water, 0.5 Gm. of potassium and sodium tartrate then added, the maceration continued, under repeated agitation, for one hour at 15° C. (59° F.), and the mixture filtered, the addition of 1 drop of ammonia water to the filtrate should not produce more than a slight turbidity (absence of more than small quantities of cinchonine or quinidine sulphates)." *U. S.*

Cinchonidine.—The alkaloid itself is not official; as usually seen it is in white, light, pulverulent masses. It is crystallizable, soluble in 1680 parts of cold and in a somewhat smaller quantity of hot water, in about 20 parts of alcohol, and in 70 parts of ether. It melts at 206.5° C. (404° F.), and on cooling becomes a solid mass of crystals at 190° C. (374° F.). The *acid sulphate* (sometimes called *bisulphate*) is much more soluble in water than the official sulphate. The *cinchonidine salicylate* is neutral and crystalline, insoluble in cold water, sparingly in hot water, easily soluble in alcohol and diluted alcohol. It may be prepared by the direct combination of salicylic acid with the alkaloid. (Rosengarten, *A. J. P.*, 1879, p. 616.) The *hydrobromide* has been employed by Gubler hypodermically. (*N. R.*, 1879, 366.)¹ Königs and Husmann having claimed to have converted cinchonine into cinchonidine by the long-continued action of, boiling amyl alcohol and solution of potassium hydroxide, Paul and Cownley have investigated this treatment. They failed to get such conversion, and consider that the cinchonine used by Königs and Husmann must have been impure. (*P. J.*, Feb. 20, 1897.)

Uses.—So far as our knowledge goes, this alkaloid influences the system similarly to quinine, the only difference being that it is less powerful. It may be given in doses one-third greater than those of quinine, but should not be relied on in severe cases.

Dose, five to ten grains (0.32 to 0.65 Gm.).

CINCHONINÆ SULPHAS. U. S.

CINCHONINE SULPHATE

(cīn-qhō-nī'næ sŭl'phās)

"The neutral sulphate $[\text{SO}_2(\text{OH})_2 \cdot (\text{C}_{19}\text{H}_{22}\text{N}_2\text{O})_2 + 2\text{H}_2\text{O}]$ of an alkaloid obtained from the bark of several species of *Cinchona*." *U. S.*
"The sulphate of an alkaloid obtained from the bark of various species of *Cinchona* and *Remijia*." *Br.* 1885.

Cinchonine Sulphas, *Pharm.* 1870; Sulfate de Cinchonine basique, *Fr. Cod.*; Schwefelsaures Cinchonin, *Cinchoninum Sulfuricum*, *Cinchoninsulfat*, *G.*; Solfato cinchonico, *It.*; Sulfato de cinconina, *Sp.*

The U. S. P. 1870 process for making Cinchonine Sulphate was as follows: "Take of the mother-water, remaining after the crystalliza-

tion of Sulphate of Quinine, in the process for preparing that salt, a *convenient quantity*; Solution of Soda, Alcohol, Diluted Sulphuric Acid, Animal Charcoal, in fine powder, each, a *sufficient quantity*. To the mother-water add gradually, with constant stirring, Solution of Soda, until the liquid becomes alkaline. Collect on a filter the precipitate formed, wash it with water, and dry it. Then wash it with successive small portions of alcohol, to remove other alkaloids which may be present. Mix the residue with eight times its weight of water, and, having heated the mixture, add gradually Diluted Sulphuric Acid until it is saturated and becomes clear. Then boil the liquid with Animal Charcoal, filter it while hot, and set it aside to crystallize. Lastly, drain the crystals, and dry them on bibulous paper. By evaporating the mother-liquid, more crystals may be obtained." *U. S.* 1870.

In consequence of its greater solubility, cinchonine sulphate remains behind in the mother water, when quinine sulphate crystallizes, in the process for preparing the latter salt. To separate it from other substances contained in the mother water, it is decomposed by solution of soda, which is preferable to potassa, as it forms a very soluble salt with sulphuric acid, whereas the potassium sulphate, being of difficult solubility, might fall with the precipitated cinchonine. The precipitate may be safely washed with small portions of alcohol, as the alkaloid is almost insoluble in that liquid when cold. It is next reconverted into the sulphate, and the solution, having been boiled with *unpurified* animal charcoal to decolorize it, and at the same time neutralize any possible excess of sulphuric acid which might interfere with the crystallization of the salt, is filtered while hot, and then allowed to stand. It is particularly important that there should be no excess of sulphuric acid while the solution is exposed to heat, as under this influence the alkaloid is much disposed to become uncrystallizable. Hence the advantage of using unpurified animal charcoal or bone black, as the calcium carbonate contained in it neutralizes any excess of the acid. The cinchonine sulphate, held in solution by the liquid while hot, is deposited by it, upon cooling, in crystals.

It may be also prepared by first obtaining cinchonine directly from one of the barks, treating this with water acidulated with sulphuric acid, added gradually until the alkaloid is dissolved, then boiling with purified animal charcoal, filtering the solution while hot, and setting it aside to crystallize.

There are two cinchonine sulphates, the neutral and the acid sulphate. The official salt is the neutral sulphate. It is in "white, hard, lustrous, prismatic crystals; odorless, permanent in the air, and having a bitter taste. At 100° C. (212° F.) it loses its water of crystallization. If crystallized from water it will contain two, and if from alcohol, one, molecule of water of crystallization. Its aqueous solu-

¹ *Cinchonidine Benzoate* may be made by Byasson's process. Sixty parts of benzoic acid are dissolved in two hundred parts of alcohol and poured into a porcelain vessel containing three thousand parts of boiling distilled water; two hundred parts of cinchonidine sulphate are dissolved in two thousand parts of water, the solution; this is precipitated with ammonia, and washed with a small quantity of cold water; the moist precipitate of cinchonidine is added to the hot solution of benzoic acid, and filtered while hot. The solution must be made faintly alkaline by the cautious addition of ammonia. On cooling, the cinchonidine benzoate separates in the form of small, thin, prismatic needles, resembling cinchonidine sulphate. The yield is about two hundred parts. (*Ph. Rec.*, 1884, p. 45.)

tion should not show fluorescence. Soluble in 58 parts of water, 10 parts of alcohol, 2300 parts of ether, and in 69 parts of chloroform at 25° C. (77° F.); soluble in 32 parts of water at 80° C. (176° F.), and in 5.2 parts of alcohol at 60° C. (140° F.). It melts at 198.5° C. (389.5° F.), and leaves no residue on incineration. Its aqueous solution is neutral to litmus paper, and is dextrogyrate. An aqueous solution of Cinchonine Sulphate (1 in 100) yields with barium chloride T.S. a white precipitate, insoluble in hydrochloric acid. One Gm. of the salt dried to constant weight at 100° C. (212° F.) should weigh not less than 0.95 Gm. (absence of an undue amount of water). A solution of the salt (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (limit of *quinine* or *quinidine* sulphates). If 1 part of the powdered salt be macerated with frequent agitation in 80 parts of chloroform, at ordinary temperatures, it should be wholly, or almost wholly, dissolved (limit of *quinine* or *cinchonidine* sulphates). The salt should not impart more than a faintly yellowish tinge to sulphuric acid (limit of *readily carbonizable, organic impurities*).^{U. S.} The acid sulphate, or bisulphate, $C_{19}H_{22}N_2O \cdot H_2SO_4 \cdot 3H_2O$, is prepared by adding sulphuric acid to the neutral sulphate. According to Baup, 100 parts are soluble in 45 parts of absolute alcohol; it is insoluble in ether. It crystallizes in rhombic octohedrons.

Cinchonine (Cinchonina U. S. 1890) $C_{19}H_{22}N_2O = 292.03$, was introduced into the U. S. P. 1880 and dropped in the 8th Revision. Several processes have been employed for the preparation of cinchonine. One of the simplest is the following: Powdered pale bark is submitted to the action of sulphuric or hydrochloric acid very much diluted, and the solution obtained is precipitated by an excess of lime. The precipitate is collected on a filter, washed with water, and treated with boiling alcohol. The alcoholic solution is filtered while hot, and deposits the cinchonine when it cools. A further quantity is obtained by evaporation. If not perfectly white, it may be made so by converting it into a sulphate with diluted sulphuric acid, then treating the solution with animal charcoal, filtering, precipitating by an alkali, and redissolving in alcohol in the manner already mentioned. It may also be obtained from the mother waters of quinine sulphate by diluting them with water, precipitating with ammonia, collecting the precipitate on a filter, washing and drying it, and then dissolving it in boiling alcohol, which deposits the cinchonine in a crystalline form upon cooling. It may be still further purified by a second solution and crystallization. Its formula is now generally accepted as $C_{19}H_{22}N_2O$, the molecular weight of which is 292.03, as proposed by Skraup, instead of the older formula, $C_{20}H_{24}N_2O$, of Pasteur. This alkaloid occurs in "white, lustrous prisms or needles, without odor, at first almost tasteless, but soon developing a bitter after-taste;

permanent in the air. Soluble, at 15° C. (59° F.), in 3760 parts of water, and in 116 parts of alcohol; in 3500 parts of boiling water, and in 26.5 parts of boiling alcohol. Also soluble in 526 parts of ether, and in 163 parts of chloroform. At 240° C. (464° F.) the crystals fuse together, and at 258° C. (496.4° F.) they melt, forming a brown liquid. When ignited, they are consumed without leaving a residue. When placed on moistened, red litmus paper, Cinchonine shows an alkaline reaction. On adding to a neutral or not more than faintly acid solution of Cinchonine, or of any of its salts, enough potassium ferrocyanide test-solution to redissolve the precipitate first formed, and afterwards an acid, a golden-yellow precipitate will be formed, which, when redissolved by gently warming the liquid, will separate, on cooling, in minute scales or needles. On adding an excess of ammonia water to a solution of Cinchonine in a diluted acid, the alkaloid will be precipitated. The precipitate is but feebly soluble in ammonia, and should require not less than 300 parts of ether for solution. A solution of Cinchonine (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of *quinine* or *quinidine*). Cinchonine should not impart more than a faintly yellowish tinge to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*).^{U. S.} 1890. Waddington found it to sublime readily, without change, in perfectly characteristic crystals. (*P. J.*, March, 1868, p. 414.) Its alkaline character is very decided, as it neutralizes the strongest acids. Of the salts of cinchonine, the sulphate, nitrate, hydrochloride, phosphate, and acetate are soluble in water. The neutral tartrate, oxalate, and gallate are insoluble in cold water, but soluble in hot water, alcohol, or an excess of acid. Winckler has shown that cinchonine is rendered uncrystallizable or amorphous by sulphuric acid in excess, aided by heat, a fact of importance in the preparation of the sulphate of this alkaloid. (*Chem. Gaz.*, March 15, 1848.) Cinchonine is but little more soluble in carbonic acid water than in pure water, and does not, like quinine, yield crystals of the carbonate on exposure of its carbonic acid solution. (*C. R. A. S.*, Nov. 7, 1853, p. 727.) It differs from quinine by its rotating the plane of polarization to the right, by the want of fluorescence in its solutions, and by its failing to respond to the thalleioquin test.

Exposed to the air, cinchonine does not suffer decomposition, but very slowly absorbs carbonic acid gas, and acquires the property of effervescing slightly with acids. It is precipitated sulphur yellow by gold trichloride. Chlorine water dissolves it or any of its salts without change; but if ammonia be now added, a white precipitate is produced. It is thus distinguishable from quinine. (See *Quinina*.) J. W. Bill, U. S. A., proposed potassium ferrocyanide as a very delicate test of cinchonine. If added to the solution of a salt of this alkaloid,

it produces a yellowish-white curdy precipitate, which is dissolved upon the application of a gentle heat, but is again deposited, when the liquid cools, as an abundant crop of golden-yellow crystals. No other alkaloid exhibits the same reaction. A cloudy precipitate is produced by the same reagent with a salt of quinine; but this does not happen when the ferrocyanide is in excess; and, if the precipitate be dissolved by heat, no subsidence takes place on cooling. Hence, in the application of this test to cinchonine, a slight excess of the ferrocyanide should be added. (*Am. J. S.*, July, 1858, p. 108.)

By the action of potassium permanganate cinchonine is decomposed, with the effect of producing, at first, an entirely distinct neutral principle, *cinchotenine*, $C_{15}H_{20}N_2O_3 + 3H_2O$, and an alkaloid, which the authors named *hydrocinchonine*, $C_{15}H_{24}N_2O$, as it differs from cinchonine (cinchonina) only in having two additional atoms of hydrogen. The cinchotenine, when further oxidized by the same reagent, yields quinoline and pyridine derivatives (see PART II), as *cinchonic* (quinoline-carboxylic acid, $C_8H_5N(COOH)$), and *cincho-meronic* (pyridine-dicarboxylic acid, $C_8H_5N(COOH)_2$).

Uses.—Cinchonine sulphate has the same remedial properties as quinine sulphate, but must be given in somewhat larger dose. It may be taken in pill, or in solution made by the addition of diluted sulphuric acid in the proportion of a minim or two drops for each grain of the salt. To lessen the bitterness in taste, it may be given suspended in syrup, without the use of any acid or with a few grains of powdered licorice added to the mixture.

Dose, tonic, a grain or two (0.065 to 0.13 Gm.) three or four times a day; antiperiodic dose, fifteen to forty grains (1.0 to 2.6 Gm.) between the paroxysms.

CINNALDEHYDUM. U. S.

CINNAMIC ALDEHYDE [Synthetic Oil of Cassia]

(cīn-nāl-dē-hy'dūm)

$C_9H_8O = 131.07$

"An aldehyde obtained from oil of cinnamon or prepared synthetically, containing not less than 95 percent. of pure Cinnamic Aldehyde [$C_6H_5.CH:CH.CO$]. It is nearly identical with the oil distilled from Cassia Cinnamon, and should be kept in small, amber-colored, well-stoppered bottles." U. S.

Aldehydum cinnamicum; Phenylacrolein; Aldehyde cinamique, *Fr.*; Zimmtsäurealdehyd, Zimmtaldehyd, *G.*

Cinnamic aldehyde was introduced into the U. S. Pharmacopœia (8th Rev.) because of its large use in place of Oil of Cassia (*Oleum Cinnamomi* U. S. P.); it has an advantage over the latter, because of its greater purity and more uniform quality as found in commerce,

Preparation.—Most of the cinnamic aldehyde in commerce is the synthetic product, which is made by oxidizing cinnamyl alcohol, by distilling a mixture of calcium cinnamate and formate to dryness, or as the result of a condensation made by acting on a mixture of benzaldehyde and acetaldehyde with hydrochloric acid gas. It has also been made by mixing 10 parts of benzaldehyde, 15 parts of acetaldehyde, and 10 parts of a 10 per cent. solution of sodium hydroxide diluted with 900 parts of water and setting aside for a week; the two aldehydes will condense, forming cinnamic aldehyde, and water will be eliminated. The reaction is as follows:

The natural product can be obtained by agitating oil of cassia with a concentrated aqueous solution of acid sodium sulphite. Soluble sodium cinnamyl-hydroxy-sulphonate, $C_6H_5.CH:CHCH(OH)SO_3Na$, is first formed, and this combines with a second molecule of the acid sodium sulphite, forming a sparingly soluble compound, $C_6H_5CHSO_3Na.CH_2.CH(OH)SO_3Na + 2H_2O$. The crystalline precipitate is separated, washed with cold alcohol and decomposed with diluted H_2SO_4 , whereby cinnamic aldehyde is formed. This is then rectified by distillation.

Properties.—It is officially described as "a colorless liquid, having a cinnamon-like odor and a burning, aromatic taste. Specific gravity: about 1.047 at 25° C. (77° F.). Optically inactive. It boils at about 250° C. (482° F.), with partial decomposition. Cinnamic Aldehyde should solidify when the temperature is reduced by a freezing mixture of ice and salt, and should melt again at -7.5° C. (18.5° F.). It is sparingly soluble in water, soluble in all proportions in alcohol, ether, and fixed and volatile oils. If the looped end of a piece of clean copper wire be held in a non-luminous flame until it glows, then cooled, and the loop dipped into Cinnamic Aldehyde, ignited, and held so that the liquid burns outside of the flame, then if the loop be slowly brought in contact with the lower outer edge of the flame, no green tinge should be discernible (absence of chlorinated products)." U. S.

Assay. U. S. (8th Rev.).—"Introduce into a counterpoised 150 Cc. flask, by means of a pipette, 12 drops of Cinnamic Aldehyde, and note the exact weight; add 5 Cc. of distilled water and a few drops of phenolphthalein T.S., and then neutralize the solution exactly by the cautious addition of tenth-normal sodium hydroxide V.S. Add 50 Cc. of a solution of sodium sulphite (1 in 5), and immerse the flask in a water-bath containing boiling water. From a burette add just sufficient half-normal hydrochloric acid V.S. to maintain the neutrality of the mixture, keeping the flask continuously heated and frequently agitated, and adding a drop or two of phenolphthalein T.S. When a permanent condition of neutrality is reached, note the number of cubic centimeters of the

half-normal hydrochloric acid V.S. consumed. Carry out a blank test identical with the foregoing, except that the Cinnamic Aldehyde is omitted, and note the amount of half-normal hydrochloric acid V.S. consumed. Subtract the number of cubic centimeters required in the blank test from the number required in the original test; each Cc. of this difference corresponds to 0.033 Gm. of Cinnamic Aldehyde. To find the percentage, multiply the above difference by 0.033 and the product by 100, and divide by the weight of the Cinnamic Aldehyde taken." U. S.

Uses.—The medicinal uses of this substance are the same as those of oil of cinnamon.

Dose, one to two minims (0.06 to 0.12 Cc.).

CINNAMOMUM SAIGONICUM. U. S.

SAIGON CINNAMON

(cîn-nâ-mô'mûm sâ-i-gôn'-cûm)

"The bark of an undetermined species of *Cinnamomum* (Fam. *Lauraceae*)." U. S.

CINNAMOMUM ZEYLANICUM.

U. S. (Br.)

CEYLON CINNAMON

(cîn-nâ-mô'mûm zê-lân'-cûm)

"The inner bark of the shoots of *Cinnamomum zeylanicum* Breyne (Fam. *Lauraceae*)." U. S. "The dried inner bark of shoots from the truncated stocks of *Cinnamomum zeylanicum*, Breyne. Obtained from cultivated trees. Imported from Ceylon, and distinguished in commerce as Ceylon cinnamon." Br.

Cinnamomi Cortex, Br.; *Cinnamomum*, U. S. 1880; Cinnamon Bark; Cortex *Cinnamomi* Zeylanici; *Cinnamomum Acutum*, s. Verum; Cannelle de Ceylan, Fr. Cod.; Cannelle, Fr.; Brauner Kaneel, Zeylonzimmt, Zimmt, G.; Canela, It.; Canela, Sp.; Kurundu, Cingalese; Karua puttay, Tamil.

Both *cinnamomum* and *cassia* were terms employed by the ancients, but whether exactly as now understood it is impossible to determine. The term *cassia*, or *cassia lignea*, has been generally used in modern times to designate the coarser barks analogous to cinnamon. It was probably first applied to the barks from Malabar, and afterwards extended to those of China and other parts of Eastern Asia. It has been customary to ascribe *cassia lignea* to the *Laurus Cassia* of Linnaeus; but the specific character given by that botanist was so indefinite, and based on such imperfect information, that the species has been almost unanimously abandoned by botanists. The barks sold as cinnamon and cassia in different parts of the world are derived from various species of *Cinnamomum*.

1. *Cinnamomum zeylanicum*, Nees, *Laurineae*, 52; Lindley, *Flor. Med.*, 329; Hayne, *Darstel. und Beschreib.*, etc., xii. 263.—*Laurus*

Cinnamomum, Linn.—This is a tree about 20 or 30 feet high, with a trunk from 12 to 18 inches in diameter and covered with a thick, scabrous bark. The branches are numerous, strong, horizontal, and declining, and the young shoots are beautifully speckled with dark green and light orange colors. The leaves are opposite for the most part, coriaceous, entire, ovate or ovate-oblong, obtusely pointed, and three-nerved, with the lateral nerves vanishing as they approach the point. There are also two less obvious nerves, one on each side arising from the base, proceeding towards the border of the leaf, and then quickly vanishing. The footstalks are short and slightly channelled, and, together with the extreme twigs, are smooth and without the least appearance of down. In one variety the leaves are very broad and somewhat cordate. When mature, they are of a shining green upon their upper surface, and lighter-colored beneath. The flowers are small, white, and arranged in axillary and terminal panicles.¹ The fruit is an oval berry, which adheres like the acorn to the receptacle, is larger than the black currant, and when ripe has a bluish-brown surface, diversified with numerous white spots. The tree emits no odor perceptible at any distance. The bark of the root has the odor of cinnamon with the pungency of camphor, and yields this principle upon distillation. The leaves have a spicy odor when rubbed, and a hot taste. A volatile oil distilled from them has been introduced into commerce.² The petiole has the flavor of cin-

¹CASSIA BUDS.—This spice consists of the calyx of one or more species of *Cinnamomum*, surrounding the young ovary, and, as stated by Martius, on the authority of the elder Nees, about one-quarter of the normal size. It is produced in China; and Reeves states that great quantities of it are brought to Canton from the province which affords cassia. The species which yields it, is in all probability the same with that which yields the bark, though it has been ascribed by Nees to *Cinnamomum Loureirii*. In favor of the former opinion is the statement of Christison, that *O. aromaticum*, cultivated in the hot-houses of Europe, bears a flower-bud which closely resembles the cassia bud when at the same period of advancement. Cassia buds have some resemblance to cloves, and are compared to small nails with round heads. The enclosed ovary is sometimes removed, and they are then cup-shaped at top. They have a brown color, with the flavor of cinnamon, and yield an essential oil upon distillation. They may be used for the same purposes as the bark.

²The cinnamon leaf oil, as formerly imported into Great Britain, was of two kinds, one containing a considerable quantity of a fatty fixed oil, perhaps cinnamon-suet from the fruit, the other a pure volatile oil. The oil was said to be obtained by distilling the leaves after maceration in sea water. It resembled the oil of cloves and pimento in sensible properties, having a brownish color, a penetrating, fragrant odor, and a very pungent taste. According to Stenhouse, it was of the sp. gr. 1.053, had an acid reaction, and consisted of eugenol, a neutral substance with the formula $C_{10}H_{16}$, and a minute proportion of benzoic acid. (P. J., xiv. 319.) This oil seems to have disappeared from commerce; but it has recently been studied by Schimmel & Co. The oil of their own distillation, as also samples distilled in Java, was limpid, sp. gr. 1.056 to 1.060, and contained 87 per cent. of eugenol, and about 0.1 per cent. of cinnamic aldehyde. A cinnamon leaf oil from the Seychelles consisted chiefly of eugenol. It is obvious, therefore, that the addition of oil of cinnamon leaves to Ceylon cinnamon oil will greatly diminish the percentage of aldehyde and raise the eugenol content, which in Ceylon cinnamon oil amounts to only 4 to 8 per cent. (*Schim. Rep.*, April, 1904).

namon. It is a singular fact that the odor of the flowers is to people in general disagreeable, being compared by some to the scent exhaled from newly-sawed bones. The fruit has a terebinthinate odor when opened, and a taste in some degree like that of juniper berries. A fatty substance, called *cinnamon-suet*, is obtained from it when ripe, by bruising it and then boiling it in water, and removing the oleaginous matter which rises to the surface, and concretes upon cooling. It is the prepared bark that constitutes the genuine cinnamon.

This species is a native of Ceylon, where it has long been cultivated. It is said also to be a native of the Malabar Coast, and has at various periods been introduced into Java, the Isle of France, Bourbon, the Cape Verds, Brazil, Cayenne, several of the West India islands, and Egypt, and in some of these places is at this time highly productive, especially in Cayenne, where the plant was flourishing so early as 1755. It is exceedingly influenced, as regards the aromatic character of its bark, by the circumstances of soil, climate, and mode of culture. Thus, we are told by Marshall that in Ceylon, beyond the limits of Negombo and Matura, in the western and southern parts of the island, the bark is never of good quality, being greatly deficient in the aromatic flavor of the cinnamon, and that even within these limits it is of unequal value, from the various influences of exposure, soil, shade, and other circumstances. Cinnamon closely resembling Ceylon cinnamon is said to have been sent to Europe from Brazil.

2. *C. aromaticum*, Nees, *Laurineæ*, 52; Lindley, *Flor. Med.*, 330.—*C. Cassia*, Blume, *Ed. Ph.*; Hayne, *Darstel. und Beschreib.*, etc. xii. 23.—*Laurus Cassia*, Aiton, *Hort. Kew.*, ii. 427.—Not *Laurus Cassia* of Linn.—This is of about the same magnitude as the former species, and, like it, has nearly opposite, shortly petiolate, coriaceous, entire leaves, of a shining green upon the upper surface, lighter-colored beneath, and furnished with three nerves, of which the two latter vanish towards the point. The leaves, however, differ in being oblong-lanceolate and pointed, and in exhibiting, under the microscope, a very fine down upon the under surface. The footstalks and extreme twigs are also downy. The flowers are in narrow, silky panicles. The plant grows in China, Sumatra, and other parts of Eastern Asia, and is said to be cultivated in Java. It is believed to be the species which furnishes, wholly or in part, the Chinese cinnamon or cassia brought from Canton, and is supposed to be the source of the cassia buds.

Besides the two species above described, others have been thought to contribute to the cinnamon and cassia of commerce. In 1839 (*Madras Journ. Lit. and Sci.*, No. 22), Wight stated that in his belief cinnamon was derived from 12 to 18 specifically distinct trees. *C. inners*, Reinw., is distinguished from *C. zeylanicum* by the nervation of its leaves, which

are also paler and thinner than those of the official plant, of which, however, it is probably only a variety. It yields the so-called *wild cinnamon* of Japan. *C. nitidum*, growing in Ceylon, Java, and on the mainland of India, is said to have been the chief source of the drug known formerly by the name of *Folia Malabathri* and consisting of the leaves of different species of *Cinnamomum* mixed together. *C. Culilawan* of the Moluccas yields the aromatic bark called culilawan, noticed in PART II of this work; and similar barks are obtained from another species of the same region, named *C. Rubrum*, and from *C. Sintoc* of Java. *Massoy bark*, from which an aromatic volatile oil is obtained called *oil of massoy*, is the product of *C. Kiamis*. (Gmelin, *Handbook*, xiv. 380.) In the mountains of Eastern Bengal, at a height of 1000 to 4000 feet, flourish *C. obtusifolium*, Nees, *C. pauciflorum*, Nees, and *C. Tamala*, W., and these, with other unknown species, afford quantities of bark which are shipped from Calcutta, Java, Timor, etc., to Europe under the name of *cassia lignea*, *cassia*, *cassia vera*, or *wild cassia*. The bark of the *C. pedatinervium*, a tree indigenous to Fiji, yields nearly one per cent. of a white aromatic volatile oil, with a pungent spicy taste. For constitution, etc., see *Proc. Chem. Soc.*, xix. These barks are mostly highly aromatic, resembling cinnamon more or less closely in flavor, and are distinguished by yielding to cold water an abundant mucilage.

Culture, Collection, Commerce, etc.—In Ceylon, cinnamon bark was originally collected exclusively from the tree in a wild state; but the Dutch introduced the practice of cultivating it, which has been continued since the British came into possession of the island. The principal cinnamon gardens are in the vicinity of Columbo, but the plant is grown from the sea-level up to a considerable elevation, giving the finest product, however, on the sandy soil of the coast line. The seeds are planted in a prepared soil at certain distances, and, as four or five are placed in a spot, the plants usually grow in clusters like the hazel-bush. In favorable situations they attain the height of five or six feet in six or seven years; and a healthy bush will then afford two or three shoots fit for peeling, and every second year afterwards from four to seven shoots in a good soil. The cinnamon harvest commences in May and continues until late in October. The first object is to select shoots proper for decortication, and those are seldom cut which are less than half an inch or more than two or three inches in diameter. Before decortication these shoots are trimmed up, and the small pieces, when dried, constitute *cinnamon chips*. The bark is divided by longitudinal incisions, of which two are made in the smaller shoots, several in the larger, and is then removed in strips by means of a suitable instrument. The pieces are next collected in bundles, and allowed to remain in this state for a short time, so as to undergo a degree of fermentation, which facilitates the separation of the epider-

mis. This, with the green matter beneath it, is removed by placing the strip of bark upon a convex piece of wood and scraping its external surface with a curved knife. The bark now dries and contracts, assuming the appearance of a quill. The peeler introduces the smaller tubes into the larger, and connects them also endwise, thus forming a congeries of quills which is about forty inches long. When sufficiently dry, these cylinders are collected into bundles weighing about thirty pounds and bound together by pieces of split bamboo. The commerce in Ceylon cinnamon was formerly monopolized by the East India Company; but the cultivation is now unrestricted, and the bark may be freely exported upon the payment of a fixed duty. It is assorted in the island into three qualities, distinguished by the designations of *first*, *second*, and *third*. The inferior kinds, which are of insufficient value to pay the duty, are used for preparing oil of cinnamon.

The exportation of cinnamon chips from Ceylon in 1902 was 1,763,679 lbs., and in 1903, 2,253,269 lbs. Immense quantities of cinnamon barks are exported from China, the finest of which is little inferior to that of Ceylon, though the mass of it is much coarser. It passes in commerce under the name of *cassia*, and is said by Reeves to be brought to Canton from the province of Kwangse, where the tree producing it grows very abundantly. (*Trans. Med.-Bot. Soc.*, 1828, p. 26.)¹ It has already been stated that this tree is supposed to be the *Cinnamomum aromaticum*; but we have no positive proof of the fact. It is, indeed, asserted that true cinnamon of very fine grade occurs in China, although it never enters foreign commerce, because of the high price which it commands at home. (*P. J.*, xxi. 1890.) These fine cinnamons are said to be produced in the mountainous district of Annam, or Cochin-China. Cinnamon of good quality is said to be collected in Java, and considerable quantities of inferior quality have been thrown into commerce, as *cassia lignea*, from the Malabar Coast. Manila and the Isle of France are also mentioned as sources whence this drug is supplied. Little, however, reaches the United States from these places. The island of Martinique, Cayenne, and several of the West India islands yield to commerce considerable quantities of cinnamon of various qualities. That of Cayenne is of two kinds, one of which closely resembles, though it does not quite equal, the aroma of Ceylon, the other resembles the Chinese. The former is supposed to be derived from plants propagated from a Ceylonese stock, the latter from plants which have sprung from a tree introduced from Sumatra. By far the greater proportion of cinnamon brought to this country is imported from China. It is entered as *cassia* and *Saigon cassia* at the custom house.

From what source the ancients derived their cinnamon and cassia is not certainly known. Neither the plants nor their localities, as de-

scribed by Dioscorides, Pliny, and Theophrastus, correspond precisely with our present knowledge; but in this respect much allowance must be made for the inaccurate geography of the ancients. It is probable that the Arabian navigators at a very early period conveyed this spice within the limits of the Phœnician and Grecian and subsequently of Roman commerce.

Properties.—*Ceylon cinnamon* is in cylindrical fasciculi, composed of numerous quills, the larger enclosing the smaller. In the original sticks, which are somewhat more than three feet in length, two or three fasciculi are neatly joined at the end, so as to appear as if the whole were one continuous piece. The finest is of a light brownish-yellow color, almost as thin as paper, smooth, often somewhat shining, pliable to a considerable extent, with a splintery fracture when broken. It has a pleasant, fragrant odor, and a warm, aromatic, pungent, sweetish, slightly astringent, and highly agreeable taste. When distilled it affords but a small quantity of essential oil, which, however, has an exceedingly grateful flavor. It is brought to this country from England, but it is costly. The inferior sorts are browner, thicker, less splintery, and of a less agreeable flavor, and are little if at all superior to the best Chinese. The finer variety of *Cayenne cinnamon* approaches in character that above described, but is paler and in thicker pieces, being usually collected from older branches. That which is gathered very young is scarcely distinguishable from the cinnamon of Ceylon. Ceylon cinnamon is officially described as in "long, closely rolled quills, composed of eight or more thin layers of bark; pale yellowish-brown; outer surface smooth, marked with wavy lines of bast-bundles; inner surface striate; fracture short-splintery; odor agreeably aromatic; taste sweet and warmly aromatic. The yield of ash, when incinerated, should not be over 4 percent." *U. S.*²

Chinese cinnamon, or *Cassia* (*Cinnamomum Cassia*. *Cassia Cinnamon*. *U. S.* 1890), occurs in tubes from one-eighth of an inch to an inch in diameter, usually single, sometimes double, very rarely more than double. In some instances the bark is rolled very much upon itself, in others is not even completely quilled, forming segments more or less extensive of a hollow cylinder. It is of a redder or darker color than the finest Ceylon cinnamon, thicker, rougher, denser, and breaks with a shorter fracture. It has a stronger, more pungent and astringent but less sweet and grateful taste, and, though of a similar odor, is less agreeably fragrant. It is the kind almost universally kept in our shops. Of a similar character is the cinnamon imported directly from various parts of the East Indies. But under the name of cassia have also been brought to us very inferior kinds of cinnamon, collected from the trunks or large branches of the trees, or in-

² For an account of the cultivation of *C. zeylanicum*, see *P. J.*, xl. 261; also one containing statistics and interesting notes on Chinese cassia in *P. J.*, 1898, 47.

¹ For method of collection, see *P. J.*, Feb. 1890.

jured by want of care in keeping, or perhaps derived from inferior species. It is said that cinnamon from which the oil has been distilled is sometimes fraudulently mixed with the genuine. These inferior kinds are detected, independently of their greater thickness and coarseness of fracture, by their deficiency in the peculiar sensible properties of the spice. Chinese cinnamon is "in quills of varying length and about 1 Mm. or more in thickness; nearly deprived of the corky layer; yellowish-brown; outer surface somewhat rough; fracture nearly smooth; odor fragrant; taste sweet, and warmly aromatic." U. S. 1890. Cassia is no longer official in the U. S. P. it having been dropped at the 8th Revision.

Saigon cinnamon takes its name from Saigon, the capital of French Cochin-China. It is a thick cassia bark, which has come into European commerce, and was recognized for the first time by the U. S. P. 1890. It is officially described as "in quills about 15 Cm. long, and 10 to 15 Mm. in diameter, the bark 2 or 3 Mm. thick; outer surface gray or light grayish-brown with whitish patches, more or less rough from numerous warts and some transverse ridges and fine longitudinal wrinkles; the inner surface cinnamon-brown or dark brown, granular and slightly striate; fracture short, granular, in the outer layer cinnamon-colored, having near the cork numerous whitish striæ forming an almost uninterrupted line; odor agreeably aromatic; taste sweet, warmly aromatic, somewhat astringent." U. S. The odor of this cinnamon is fragrant, the taste is highly aromatic, markedly that of cinnamon, and, in the specimens that we have seen, only slightly astringent. It also occurs in commerce much broken, in which state it commands a somewhat smaller price than in quills. The Saigon buds also are brought into the port of New York. The quality of Saigon cassia, as it is commonly termed in trade journals, is distinctly superior to that of other cassias, and the price which it commands much higher. It is obtained from the *Cinnamomum Loureirii* of Nees, the *Laurus Cinnamomum* of Loureiro, a tree which grows in Cochin-China and Japan. According to Siebold, the bark of the large branches is of inferior quality and is rejected; that from the smallest branches resembles the Ceylon cinnamon in thickness, but has a very pungent taste and odor, and is little esteemed, while the intermediate branches yield an excellent bark, about a line in thickness, which is even more highly valued than the cinnamon of Ceylon, and yields a sweeter and less pungent oil. It yields about 2 per cent. of a volatile oil, the oil of Nikkei, having an odor resembling that of cinnamon and citral, a specific gravity at 15° C. of 0.9005, and containing about 27 per cent. of aldehyde, chiefly citral.

Powdered cinnamon is often grossly adulterated with sugar, ground walnut shells, galanga rhizome and various other substances. Galanga, according to Schmitz-Dumont, may be detected

by the presence of small club-shaped, rod-shaped, partly bent, microscopic pieces of resino-tannol. (*Ztschr. f. oeff. Chem.*, 1903, No. 2.) Powdered cassia buds are frequently added to the inferior cinnamon powders, but can hardly be looked upon as an adulterant, as they contain a larger proportion of volatile oil than the lower grades of cinnamon.

The *Pharmacographia* gives the following tests for distinguishing powdered cassia from powdered cinnamon, and for recognizing the inferior varieties of cassia. Make a decoction of powdered cinnamon of known genuineness, and one of similar strength of the suspected powder; when cool and strained, test a fluid-ounce of each with one or two drops of tincture of iodine. A decoction of cinnamon is but little affected, but in that of cassia a deep blue-black tint is immediately produced. The cheap kinds of cassia known as *cassia vera* may be distinguished from the more valuable Chinese cassia as well as from cinnamon by their richness in mucilage; this can be extracted by cold water; it is a thick glairy liquid, giving dense rosy precipitates with corrosive sublimate or neutral lead acetate, but not with alcohol.¹

Microscopic Structure.—Ceylon cinnamon usually consists simply of liber, the outer coatings having been stripped off during its preparation for market. Three layers are distinguishable in the liber. "1. The external surface, which is composed of one to three rows of large thick-walled cells, forming a coherent ring; it is only interrupted by bundles of liber fibres, which are obvious even to the unaided eye. 2. The middle layer is built up of about 10 rows of parenchymatous thin-walled cells, interrupted by much larger cells containing deposits of mucilage, while other cells not larger than those of the parenchyme itself are loaded with essential oil. 3. The innermost layer exhibits the same thin-walled but smaller cells, yet intersected by narrow somewhat darker medullary rays, and likewise interrupted by cells containing either mucilage or essential oil, instead of bundles of liber fibres. Fibres mostly isolated are scattered through the two inner layers, the parenchyme of which abounds in small starch granules accompanied by tannic matter. On a longitudinal section the length of the liber fibres becomes more evident, as well as oil-ducts and gum-ducts." (*Pharmacographia*.)

The coarser cassia bark, or *cassia lignea*, usually has some of the external or corky layer adherent to it, and always the parenchymatous mesophlæum or middle bark, but the liber constitutes the chief mass. Isolated liber fibres and thick-walled cells (stone cells) are scattered

¹ The German Pharmacopœia requires that cinnamon shall yield not more than 5 per cent. of ash, with 1 per cent. of sand. G. Rupp (*Süddeutsch. Ap. Ztg.*, 1899, 267) finds it, however, difficult to get commercial cinnamon that will come up to these requirements. A Chinese cinnamon examined gave 5.79 per cent. of ash, with 2.83 per cent. of sand, while commercial Ceylon cinnamon yielded 6.1 per cent. of ash, with 2.4 per cent. of sand.

even through the outer layers of a transverse section. In the middle zone they are numerous, but do not form a coherent sclerenchymatous ring as in Ceylon cinnamon. The innermost part of the liber shares the structural character of cinnamon, with differences due to age, as, for instance, the greater development of the medullary rays. Oil cells and gum ducts are likewise distributed in the parenchyme of the former. The finest cassia or Chinese cinnamon has the three layers described in Ceylon cinnamon, but is distinguished by the adherent outer parenchymatous and suberous layer.

Chemical Composition.—According to the analysis of Vanquelin, cinnamon contains a peculiar volatile oil, tannin, mucilage, a coloring matter, an acid, and lignin. The tannin is of the variety which yields a greenish-black precipitate with the salts of iron. Thos. R. Thornton (*A. J. P.*, 1895, 400) has examined the tannin of *C. Cassia*. He found it to amount to about 3.90 per cent., as an average of three different determinations on different samples. He found it impossible to extract the tannin by any one of several methods tried, and concludes that it either has the phlobaphene (anhydride) character as it exists in the drug or acquires such character when brought into contact with water. Jas. A. Ferguson (1887), in the laboratory of the Philadelphia College of Pharmacy, determined the ash of several samples of Ceylon cinnamon, finding an average of 4 per cent., while in powdered *cassia cinnamon* he found 2.8 and 2.5 per cent. (*A. J. P.*, 1887, 278, 279.) The oil obtained from the Cayenne cinnamon was found to be more biting than that from the Ceylon. Bucholz found in 100 parts of *cassia lignea* 0.8 of volatile oil, 4.0 of resin, 14.6 of gummy extractive (probably including tannin), 64.3 of lignin and bassorin, and 16.3 of water, including loss.

This aromatic yields its virtues wholly to alcohol, and less readily to water. At the temperature of boiling alcohol very little of the oil rises, and an extract prepared from the tincture retains, therefore, the aromatic properties. For an account of the volatile oil, see *Oleum Cinnamomi*.

Uses.—Cinnamon is among the most grateful and efficient of the aromatics. It is warm and cordial to the stomach, carminative, distinctly astringent, and, like most other substances of this class, more powerful as a local than as a general stimulant. It is seldom prescribed alone, though, when given in powder or infusion, it will sometimes allay nausea, check vomiting, and relieve flatulence. It is chiefly used as an adjuvant, and enters into a great number of official preparations. It is often employed in *diarrhæa*, in connection with chalk and astringents, and is of value in *menorrhagia*.

Dose., of powder, ten to twenty grains (0.65 to 1.3 Gm.).

COCA. U. S. (Br.)

COCA [Erythroxylon]

(cō'cā)

"The dried leaves of *Erythroxylon Coca* Lamarek (Fam. *Erythroxylaceæ*), known commercially as Huanuco Coca, or of *E. Truxillense* Rusby, known commercially as Truxillo Coca, yielding when assayed by the process given below, not less than 0.5 percent. of the ether-soluble alkaloids of Coca." U. S. "The dried leaves of *Erythroxylum Coca*, Lam., and its varieties." Br.

Cocæ Folia, Br.; Coca Leaves; Cuca; Coca, Fr. *Cod.*; Feuilles de Coca, Fr.; Cocablätter, G.; Coca, It.; Coca del Peru, Ipadu, Sp.

The coca plants are shrubs or small trees, some of the species reaching the height of fifteen or twenty feet. It is conjectured that the original habitat was in the Peruvian mountains, from 7° South to 10° North, but either spontaneously or through cultivation the coca shrubs have spread until they are found in the whole Eastern curve of the Andes, from the Straits of Magellan to the borders of the Caribbean Sea, growing on the moist sides of the mountains at the elevation of 1,500 to 6,000 feet, the climatic requisites being moisture and equable temperature, with a mean of about 64° F. The wild coca shrub commonly reaches the height of 12 feet, and some species of the genus to 18 feet, but the cultivated coca is usually kept down to about 6 feet. The leaves are gathered three times a year; the first harvest, or preliminary picking, is taken at the time of the trimming of the bushes, from the cut-off twigs. Then, about the end of June, a scanty crop is gathered, while the last crop of the season is gathered in October or November. Harvesting must always take place in dry weather, so that the fresh leaves when spread out in layers two or three inches thick on the drying pavement can be collected in six or eight hours.

The coca plant, which is propagated from the seed in nurseries, begins to yield in eighteen months, and continues productive for half a century. The leaves, when mature, are carefully picked by hand so as to avoid breaking them or injuring the young buds, are slowly dried in the sun, and are then packed in bags (*cestos*) holding from twenty-five to one hun-

dred and fifty pounds each. They were in general use among the natives of Peru at the time of the conquest, and have continued to be much employed to the present time. It is affirmed that nearly ten million dollars' worth, or forty million pounds, are annually produced, some plantations yielding three or four harvests a year. For details as to method of cultivation, etc., see *T. G.*, Jan. 1886; also *C. D.*, 1897, 182. Two varieties of the coca leaf occur in the commerce of the United States, namely, the so-called Huanuco coca and the Truxillo coca, the Huanuco variety being produced in Bolivia, Huanuco, Brazil, Venezuela and Argentina, while the Truxillo coca is produced chiefly in Northern Peru. The great variation in the leaves and other portions of the coca plant, produced by its long continued cultivation, has produced much doubt and discussion as to the specificity and characteristics of the plant; H. H. Rusby has, however, by elaborate study of the subject (*D. C.*, Nov. 1900) solved the problem.

Huanuco coca has been for a long time believed to be obtained from *Erythroxylon Coca*; this belief is confirmed by Rusby and has been accepted by the Pharmacopœial authorities. The plant was first described in 1786, in *Lamarck's Dictionary*, vol. ii. 393.

Truxillo coca is the product of the *E. Coca Spruceanum* of Burck; the name "spruceanum" was, however, preoccupied before it was used by Burck, and in obedience to the ordinary rules of botanical nomenclature it was changed by Rusby, who regards it as a distinct species, to *E. Truxillense*.

Coca is cultivated in the British East and West Indies, and in Java, and the product is said to appear, in the London markets, under the names of Truxillo coca and Java coca. This coca is entirely distinct from the Truxillo coca of the American market, and does not reach the United States. The coca shrubs of India and Ceylon are the offspring of plants originally sent out from Kew Gardens, which plants were derived from seeds obtained in Huanuco, and were considered by Morris as representing a distinct variety of *E. Coca* to which he gave the name of *E. Nova-Granatense*. According to Rusby, however, this plant is a distinct species, and the same as that previously described by Jacquin, from Colombia, under the name of *E. carthagenense* (the name *E. carthagenense* not being, as it is held in the Kew Index, a synonym of *E. areolatum*).¹

¹ The commercial value of cocaine has led to the examination by Eykmann of Java, and Howard of Kew Gardens, of various species of the genus *Erythroxylon*, other than *E. Coca*; in a number of species the alkaloid was found, but always in too small quantities for commercial purposes. (For details, see *P. J.*, Jan. 1889.) The South American coca is said to vary from 0.02 per cent. up to 1.02 per cent., or even more, in the yield of alkaloids, the average being according to Hesse, in good specimens about 0.8 per cent. Parke, Davis & Co., however, write us that in a very large number of chemical assays they have never been able to obtain more than 0.5 per cent. of cocaine out of any South American coca. It is possible that alkaloidal deterioration occurs during transportation. According to Warden, the alkaloidal yield of India coca varies from 0.36 to 1.67

Properties.—The leaves of the different varieties of coca do not, on the whole, resemble one another at all closely, but are distinguished from most other leaves by a slightly curved line on each side of the mid-rib, running from the base to the apex. This line has the appearance of a rib but is really not of this character, having been produced during development by the peculiar folding of the leaf in the bud. The two commercial varieties are very well described in the U. S. Pharmacopœia as follows:

"Huanuco Coca.—Greenish-brown to clear brown, smooth and slightly glossy, thickish and slightly coriaceous, stoutly and very shortly petioled; blade 2.5 to 7.5 Cm. long and nearly elliptical, with a very short and abruptly narrowed basal portion and a short point, the margin entire; midrib marked above by a slight ridge, very prominent underneath, the remaining venation rather obscure, especially above; underneath, a conspicuous line of collenchyma tissue runs longitudinally on either side of the midrib and about one-third of the distance between it and the margin, the enclosed areola being of a slightly different color from the adjacent surface; odor characteristic; taste bitterish, faintly aromatic, followed by a numbness of the tongue, lips, and fauces.

Truxillo Coca.—Pale green, thin, brittle and usually much broken, smooth but not shining, shortly and stoutly petioled; blade 1.6 to 5 Cm. long and one-third to one-half as broad, obovate to oblanceolate, narrowed from near the middle into the petiole, usually with a slight projecting point at the summit, the margin entire; underneath two irregular lines of collenchyma tissue, usually incomplete or obscure, and frequently wanting, run beside the midrib at about one-third the distance from it to the margin; odor more tea-like than that of Huanuco Coca; taste and numbing effect similar." *U. S.*² "The midrib itself is prolonged into

per cent. The government chemists in Java report that the Java leaf contains over 2 per cent. of cocaine; but a sample obtained directly from Java by Parke, Davis & Co. yielded only 1.06 per cent. of total alkaloids. The total yield of alkaloids is not an exact criterion of the value of the leaves, because in some, and it is said especially in the Ceylon and Java coças, cocaine constitutes only a small proportion of the total alkaloids. It is not possible to determine the alkaloidal value of a coca by its physical properties, so that at present the large manufacturers of cocaine buy the drug by assay.

It is interesting to note that C. J. H. Warden states (*P. J.*, May, 1888) that India coca can be distinguished by the peculiarities of its cocatannic acid.

² In a series of measurements of the Bolivian and Truxillo leaves, H. G. Greenish (*P. J.*, 493) found that the difference in thickness in the two varieties is more apparent than real, the same-sized leaves of the two varieties having the same thickness but the Huanuco leaves averaging much larger and therefore thicker than the others. The chief cause of the lesser fragility of the Huanuco leaf was found to be due to the thickening and lignification of cells in the parenchyma, the increased development of pericyclic fibres in the veinlets, and the increased development of sclereids in the neighborhood of the lines of the under surfaces of the leaf. Greenish affirms that the two leaves can be microscopically distinguished by the fact that the veinlets of the Bolivian leaf are connected with both the upper and the lower epidermis by a bridge of thick-walled lignified fibrous cells.

a minute horny apiculus, which, however, is frequently broken off. Most of the epidermal cells of the under surface are seen in transverse section to project in the form of small papillæ." Br.

Chemical Constitution.—In 1853, Wackenroder demonstrated the existence of tannic acid in coca leaves, and in 1859, Stanislaus Martin found in them a peculiar bitter principle, resin, tannin, an aromatic principle, extractive, chlorophyll, a substance analogous to theine, and salts of lime. Previous to this (1855) Gardeke had isolated the crystalline alkaloid and given it the name of *erythroxyline*. Albert Niemann of Goslar, made the first thorough investigation of the leaves, and gave to the alkaloid the name it now usually bears of *cocaine*.¹ The following was his process. The leaves were exhausted with 85 per cent. alcohol acidulated with 2 per cent. of sulphuric acid; the tincture was treated with milk of lime and filtered; the filtrate was neutralized with sulphuric acid, and the alcohol distilled off. The syrupy residue was treated with water to separate resin, and then precipitated by sodium carbonate. The deposited matter was exhausted by ether, and the ethereal solution, after most of the ether had been distilled, was allowed to evaporate spontaneously. The cocaine was thus obtained in colorless crystals, mixed with a yellowish-brown matter of a disagreeable odor, which was separated by washing with cold alcohol. E. R. Squibb's process for cocaine and its hydrochloride is as follows. Coarsely ground coca leaves are reperlcolated with an aqueous five per cent. solution of sulphuric acid, and a very dense, slightly acid percolate is obtained; this is thoroughly agitated with pure coal oil and an excess of sodium carbonate; the liberated alkaloid is retained by the coal oil, and is nearly free from coloring matter; the oily solution is then agitated with acidulated water, and again precipitated by sodium carbonate in the presence of ether. The ethereal solution of cocaine is treated with diluted hydrochloric acid fractionally, and the nearly colorless solutions of cocaine hydrochloride are cautiously evaporated in shallow

porcelain pans almost to dryness. The product is in the form of a white, crystalline, granular powder, and is a nearly pure anhydrous salt. (*Ephem.*, 1887, 906.) For Henrique's process see *Proc. A. Ph. A.*, 1895, 999. Pure cocaine is in colorless, transparent prisms, inodorous, of a bitterish taste, soluble in 704 parts of cold water, more soluble in alcohol, and freely so in ether. The solution has an alkaline reaction and a bitterish taste, leaving a peculiar numbness on the tongue. The alkaloid melts at 98° C. (208.4° F.), and on cooling congeals into a transparent mass, which gradually becomes crystalline. Heated above this point it changes color, and is decomposed. It is inflammable, burning with a bright flame, and leaving charcoal. With the acids it forms soluble and crystallizable salts, which are more bitter than the alkaloid itself. The formula is $C_{17}H_{21}NO_4$. (See *Cocaine Hydrochloridum*, p. 374.) Niemann also obtained wax, a variety of tannic acid (*cocatannic acid*), and a concrete volatile odorous substance. The presence of *hygrine* in coca leaves is not confirmed. Lossen has examined cocaine, and ascertained that when heated with hydrochloric acid it splits into benzoic acid, methyl alcohol, and a new base which he calls *ecgonine*, of which the formula is $C_8H_{15}NO_3$. Cocaine is, therefore, ascertained to be *methylbenzoyl-ecgonine*,

benzoyl-ecgonine, which also occurs in coca leaves, is $C_{16}H_{19}NO_4$. Cocaine is thus seen to be the methyl ether of this latter. The fundamental

forms monoclinic prisms melting at 198° C. A considerable number of closely allied alkaloids, all of which appear to be derivatives of ecgonine, are found in the leaves of *Erythroxylon Coca*. The following list is given in Allen (*Com. Org. Anal.*, 2d ed., vol. iii. part ii., 271), on the authority of Paul and Cownley:

$C_9H_{13}NO_3$, *Anhydro-ecgonine*.

$C_9H_{15}NO_3$, *Ecgonine*.

$C_{16}H_{19}NO_4$, *Benzoyl-ecgonine*.

$C_{17}H_{21}NO_4$, *Benzoyl-ecgonine methyl ester* (*cocaine*).

$C_{18}H_{23}NO_4$, *Cinnamyl-ecgonine*.

$C_{19}H_{25}NO_4$, *Cinnamyl-ecgonine methyl ester*.

$C_{38}H_{45}N_2O_8$, *Cocayl-ecgonine methyl ester* (*cocamine*).

$C_{40}H_{50}N_2O_8$, *Homo-cocamine*.

$C_{17}H_{19}NO_3$, *Benzoyl-pseudotropine*.

With the exception of ecgonine and anhydro-ecgonine, all of the bodies in the foregoing list are saponifiable, splitting up when heated to from 80° to 100° C. with hydrochloric acid, or when boiled with alcoholic potassium hydroxide.

As the separation of cocaine from the accompanying alkaloids and products of hydrolysis is difficult, Liebermann (*Ber. d. Chem. Ges.*,

¹ *Benzoyl* ψ *Tropein*. *Tropacocaine*, $C_9H_{14}NO_4$. C_7H_5O . This compound, belonging chemically to the class of Tropeines (see Atropine), was isolated by Geisel from a narrow-leaved coca plant from Java. (*Ber. d. Chem. Ges.*, xxiv. p. 2336.) It is obtained as an oil, which when quite dry solidifies in radiating crystals, melting at 49° C. It has a strong alkaline reaction, and is easily soluble in alcohol, ether, chloroform, benzene, and petroleum benzol. It is decomposed by heating with hydrochloric acid into benzoic acid and pseudo-tropine, $C_8H_{15}NO$.

Tropacocaine has been studied by Arthur P. Chadbourne, who finds that its general action on the system resembles that of cocaine, and that although it is capable of causing death by paralyzing the respiratory centres, and is also in overdose a powerful cardiac depressant, it nevertheless is very much less poisonous than cocaine. On the other hand, Chadbourne's experiments and the clinical researches of Schweigger seem to show that tropacocaine as a local anæsthetic is much more powerful and prompt in its action than cocaine. Notwithstanding various favorable reports, tropacocaine, has, however, failed to come into use as a local anæsthetic.

xxi. 3196) has proposed a synthetic method which avoids these difficulties and at the same time utilizes the amorphous by-products. The mixed bases are boiled with hydrochloric acid, whereby they all suffer hydrolysis with formation of ecgonine; then, by passing dry hydrochloric acid into a solution of ecgonine hydrochloride in methyl alcohol, the hydrochloride of ecgonine methyl ester is formed, which on concentrating the alcoholic solution crystallizes out in prisms. Cocaine is formed when this compound is heated on the water bath with an equal weight of benzoyl chloride until the mixture becomes homogeneous and the evolution of hydrochloric acid ceases. The melted mass is poured into water and separated from the insoluble benzoic acid, when the cocaine is precipitated by ammonia and recrystallized from alcohol. Hesse investigated addition products of ecgonine and produced a crystalline compound of ecgonine and methyl iodide, $C_9H_{15}NO_3$, $CHI_3 + H_2O$, and a methyl chloride compound, $C_9H_{15}NO_3, CH_3Cl + H_2O$. (*P. J.*, 1902, 275.) He also extracted four definite compounds, not alkaloids, from the leaves of coca obtained from Java. These bodies are 1. *Cocacitrin*, $C_{23}H_{32}O_{17}$, a yellow crystalline compound with three molecules of water, melting at $186^\circ C$. This appears to be a glucoside, yielding a sugar, *cocaoose*, which may be identical with *dextrotalose*, since its *osazone* melts at $180^\circ C$. 2. *Cocacetin*, $C_{16}H_{22}O_7$, forming yellow needles with three molecules of water of crystallization. This melts at 260° to $265^\circ C$. 3. *Cocaflavin*, $C_{34}H_{38}O_{12}$, which forms yellow crystals with four molecules of water. It yields dextrose and galactose on hydrolysis with diluted sulphuric acid, and is, therefore, probably a glucoside. 4. *Cocaflavetin*, containing two methoxy groups, forms greenish-yellow needles with three molecules of water and melts at $230^\circ C$. (*P. J.*, April, 1903, 535.) The tannin of coca leaves strikes a green-black with ferric salts, and has received the name of *cocatannic acid*. Romburgh detected traces of methyl salicylate in the distillate from coca. (*Chem. Ztg.*, 1895, 130.)

Assay. U. S. (8th Rev.)—"Coca, in No. 60 powder, ten grammes; Chloroform, Ether, Normal Sulphuric Acid V.S., Ammonia Water, Distilled Water, Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin or Iodeosin T.S., each, a sufficient quantity. Place the Coca in an Erlenmeyer flask, add 50 Cc. of a mixture of chloroform 1 volume and ether 4 volumes and insert the stopper securely. Allow the flask to stand ten minutes, then add 2 Cc. of ammonia water mixed with 3 Cc. of distilled water, and shake the flask well, at frequent intervals, during one hour. Then transfer as much as possible of the contents of the flask to a small percolator which has been provided with a pledget of cotton packed firmly in the neck, and inserted in a separator containing 6 Cc. of normal sulphuric acid V.S., diluted with 20 Cc. of distilled water. When the liquid has passed

through the cotton, pack the Coca firmly in the percolator with the aid of a glass rod, and, having rinsed the flask with 10 Cc. of chloroform-ether mixture, transfer the remaining contents of the flask to the percolator by the aid of several small portions (5 Cc.) of a chloroform-ether mixture, using the same proportions as before, and continue the percolation with successive small portions of the same liquid (in all 50 Cc.). Next, shake the separator well for one minute, after securely inserting the stopper, and when the liquids have completely separated, draw off the acid liquid into another separator. Add to the chloroform-ether mixture 10 Cc. of a sulphuric acid mixture, using the same proportions as before, agitate well and again draw off the acid liquid. Repeat this operation once more, drawing off the acid solution as before into the second separator, introduce a small piece of red litmus paper, add ammonia water until the liquid is distinctly alkaline, and shake out with 3 successive portions of ether (25, 20, and 15 Cc.). Collect the ether-solutions in a beaker, place it on a water-bath filled with warm water, and allow the ether to evaporate entirely. Dissolve the residue in 3 Cc. of ether, and let this also evaporate completely. To the alkaloidal residue add 4 Cc. of tenth-normal sulphuric acid V.S. and 5 drops of hematoxylin or iodeosin T.S., then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 4 (the 4 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.03 and this product by 10, to obtain the percentage of ether-soluble alkaloids contained in the Coca." U. S. For methods of assaying coca leaves, see Lyons, *Ch. Ph.*, Sept. 1885; Squibb, *Ephem.*, 1887; Dahme, *Proc. A. Ph. A.*, 1893, 159; Prescott, *Organic Analysis*; *Proc. A. Ph. A.*, 1895, 268; *P. J.*, 1896, 1901, 222, 254; *Ph. Ztg.*, 1901, 965.

Uses.—As a nerve stimulant, coca has been used immemorially by the Peruvian and Bolivian natives. In 1853, Weddell stated that it produces a gently excitant effect, with an indisposition to sleep, in these respects resembling tea and coffee; also that it will support the strength for a considerable time in the absence of food, but does not supply the place of nutriment, and probably in this respect also acts like the two substances referred to. The Indians, while chewing it, mixed with some alkaline substance, as the ashes of certain plants, or lime, pass whole days in travelling or working without food. It is, however, clearly proved that these leaves do not take the place of nutriment, but simply put off the sense of fatigue and hunger, the Indian making up at his evening meal for the day's abstinence. It is probable that they prevent hunger simply by their local benumbing influence upon the nerves of the stomach. Their moderate habitual use

does not seem to be injurious, but the habit is said readily to grow upon the person, and finally the inveterate excessive coca-chewer can be recognized by his uncertain step, general apathy, sunken eyes surrounded by deep purple aureoles, trembling lips, green and crusted teeth, and excessively fetid breath, with peculiar blackness about the corners of the mouth. An incurable insomnia is apt to be developed, emaciation becomes extreme, dropsy appears, and even death results from a condition of general marasmus. When coca is taken in a single large dose it produces a condition of peculiar physical beatitude and calm, followed by a sensation of excessive power, which is affirmed to be accompanied by a real increase of physical ability. Mantegazza took in the course of two hours about 900 grains of the coca leaf, with the result of great increase in the number of the heart-beats and a condition of intoxication resembling that produced by hasheesh. He was possessed by a feeling of intense joyousness, while a succession of visions and phantasmagoria, most brilliant in form and color, trooped rapidly before his eyes. He then passed into a condition of delirious excitement, which was succeeded by a deep sleep lasting three hours.

The symptoms which have just been detailed are those which have been recorded by various writers as produced by the coca leaf in the land of its growth, and especially upon the natives of the country. The action of the alkaloid cocaine, and even of the drug coca, upon North Americans and Europeans, differs essentially from these effects.¹ Numerous cases of poisoning have occurred from the alkaloid; P. Mannheim has collected as many as ninety-nine (*Cleveland Med. Gaz.*, Sept. 1891). In mild cases the ordinary symptoms have been great restlessness and nervous excitement, but no sense of beatitude, rather a condition of fear and terror. With this state come usually distinctly accelerated pulse, increased frequency of respiration, and, perchance, muscular twitchings or even mild convulsions. In the more severe cases of poisoning the symptoms vary; sometimes there have been nausea, vomiting, rapid almost imperceptible pulse, great perspiration, collapse with or without loss of consciousness; in other cases the pulse has been slow and feeble, and sometimes pronounced cya-

nosis, with slow or almost arrested respiration, has been the most alarming manifestation. The pupils are usually dilated, but are reported in some cases as "contracted." After very large doses convulsions usually occur; they are often violent and epileptiform; not rarely, they are partial, and in many cases opisthotonos has been pronounced. Consciousness rarely escapes; usually it is lost, but sometimes it is merged into a mania with hallucinations and delusions, which mania may become violent and even homicidal, as in a case reported by Mattison. Poisoning has followed both the internal administration and the local uses of the alkaloid. The occasional over-effects of small doses are quite remarkable; thus, four drops of a two per cent. solution in the eye produced in an old lady intoxication which persisted four days; eight drops of a ten per cent. solution in the eye of a girl of twelve years caused violent poisoning; and even one drop of a one per cent. solution in the eye of a child fourteen years old is said to have been followed by violent symptoms. A number of cases are on record in which one grain of the alkaloid given hypodermically has caused severe fainting. Death is reported in several cases from the local use of the remedy, and twelve drops of a four per cent. solution given hypodermically to a girl of eleven caused death in forty seconds. On the other hand, large doses have been recovered from, twenty-two grains by the mouth, ten grains hypodermically, five grains hypodermically, and six grains hypodermically. (See H. C. Wood's *Therapeutics*.)

Although cocaine has been used an enormous number of times as a local application without much stint, and although doses have been given of two grains, it is evidently not safe to apply more than three-fourths of a grain to the mucous membrane of an adult, or to give more than the same amount at a dose, or to use hypodermically more than half a grain.

Cocaine is a cerebral stimulant, producing peculiar mental excitement, ending after large toxic doses in narcosis, with epileptiform convulsions, which are probably of cerebral origin. In the poisoning there is at first increased reflex activity, followed by paralysis of voluntary motion and of reflex activity, which are chiefly due to a direct action upon the spinal cord, the sensory side of the cord being probably more sensitive to the drug than the motor side. Toxic doses depress and finally paralyze the sensory nerves, and in a much less degree the motor nerves. The action of cocaine upon the circulation is less pronounced than is its influence upon the nervous system, but is distinct. By stimulation of the heart and of the vasomotor centres, and perhaps of the vascular muscle fibres, the arterial pressure is increased, while the pulse is accelerated, probably by a depression of the cardio-inhibitory apparatus. Toxic doses of cocaine produce sooner or later a fall of the arterial pressure, which appears to be the result of a

¹ The reason of this difference is not evident. Rusby found that coca treated with Mayer's reagent both before and after exportation gave evidence of a much larger percentage of the alkaloid before the exportation. He believes that during exportation the leaves lose largely of some volatile substance, probably *hygrine*. According to Hesse, however, *hygrine* is not an alkaloid of coca, but is a foreign body due to impurities in the reagents employed. (*P. J.*, vol. xx, p. 1135, 1891; also vol. xxii, p. 102.) H. C. Wood made some not very thorough tests with preparations of coca made in South America from the fresh drug under the supervision of Rusby and furnished by Parke, Davis & Co., and was not able to detect any difference between their action and that of the parallel preparations made in this country. At present it seems probable that the difference of action under discussion is due simply to difference of race, precisely as with the effects of hasheesh upon Asiatics and upon Europeans.

direct action upon the heart, and the vaso-motor system. Upon striated muscles cocaine appears to have a peculiar though very feeble action, which is not manifested during poisoning by it. It is a stimulant to the respiratory centres, increasing the rapidity and fulness of the respirations, but if the dose is sufficiently large, it causes the respirations to become after a time very shallow, and finally paralyzes the respiratory centres. Moderate doses are said to increase, large doses to paralyze, peristalsis.

It has no distinct effect upon the amount of urine secreted but probably decreases the elimination of urea. It is an energetic mydriatic but does not increase intra-ocular pressure nor entirely paralyze the accommodation. Locally applied, cocaine is a very distinct and certain anæsthetic, acting, according to the observations of von Anrep, upon the nerves of special sense as well as upon those of common sensibility. Cocaine penetrates mucous membranes readily, but is not able to pass through the skin, and when given hypodermically so rapidly diffuses itself that its local anæsthetic influence is very fugacious unless the circulation in the part be controlled by mechanical means. Injected so as to come immediately in contact with the large nerve-trunk, it is capable of producing temporary anæsthesia over the whole distribution of the nerve. When applied in concentrated solution to the mucous membrane, it produces at once a marked pallor, which is probably due to a powerful constriction of the blood-vessels caused by a direct action upon their muscle-fibres. In practical medicine cocaine is used for its local effects in benumbing sensibility and relieving pain in all mucous tracts that can be reached by the surgeon. When prescribed in an ointment, soluble salts of cocaine should be used, and sufficient water directed to prevent crystallization. In burns, painful ulcers, fissures of the anus, etc., cocaine is a very valuable remedy. It is also employed with success in various local inflammations of the mucous membrane, subduing nervous irritability, and by its constringing influence relieving or even curing acute inflammations. Thus, a mixture of cocaine and bismuth will often arrest an acute coryza. In hay fever, in the irritated sore throat of advanced phthisis, in chronic laryngitis, in inflamed hemorrhoids, and even in bronchitis with excessive cough, it often may be locally applied with advantage. The fugaciousness of its effects makes it a valuable mydriatic when it is desired simply to examine the eye-ground. The strength of the solution for local application may vary from 2 to 10 per cent., according to the effects desired. In coryza and hay fever bougies made with cacao butter, containing each from one-quarter to one-half grain of cocaine, are often very efficacious. At one time it was supposed that cocaine would be of great service by its stimulant influence in melancholia, neurasthenia, hysteria, and allied disorders, but experience has shown it to be of very little value

in these conditions, and often to increase the symptoms, especially any existing restlessness. It is chiefly valuable as an internal remedy and for its local influence upon the gastro-intestinal tract in seasickness, excessive vomiting, gastrodynia, and even in serous diarrhœa.

The habitual use of cocaine as a stimulant has in many cases led to the formation of the cocaine habit, with the production of ill health, accompanied by headache, malaise, insomnia, prostration, often faintness, vertigo, and deterioration of the cerebral function. A symptom which is said to be characteristic of chronic cocaine poisoning but which must certainly be rare, was first described by Magnan, and is known as Magnan's symptom. It consists of an hallucination of common sensation, the feeling that some foreign body is under the skin, with an often consequent complaint that grains of sand, worms, or other foreign body are situated in the position named. The immediate withdrawal of the cocaine in cases of the cocaine habit is not usually followed by any serious danger to life; symptoms that may arise are to be met on general principles.

If given in infusion the leaves should be swallowed, as it is by no means certain that they yield their virtues to water. The fluidextract is now official, and is a very eligible preparation; a tincture of coca, made in the proportion of one part in five of diluted alcohol, and a wine of coca, one in ten, would also be efficient. The elixir of coca, as usually dispensed, is too weak to be of much value. (See PART II.)

Dose, of coca, one-half to one drachm (2.0 to 3.9 Gm.).

COCAINA. U. S., Br.

COCAINE

(cō-că-ī'nă)

$C_{17}H_{21}NO_4 = 300.92$

"An alkaloid [$C_8H_{13}(C_6H_5CO)NO.COOC H_3$] obtained from several varieties of Coca." U. S. "An alkaloid, $C_{17}H_{21}NO_4$, obtained from the leaves of *Erythroxylum Coca*, Lam., and its varieties." Br.

Benzoyl-ecgonine-methyl-ester; Benzoyl-methyl-ecgonine; Cocainum; Cocaine, Fr. Cod.; Cocain, G.

The processes for making this alkaloid will be found under *Coca*. Owing to the small yield, it is found more profitable to manufacture cocaine in South America and export it, thus saving the expense of transporting the bulky coca leaves.

Properties.—It is officially described as in "large, colorless, four-sided or six-sided monoclinic prisms, having a slightly bitter taste, and producing on the tongue a temporary numbness. Soluble in 600 parts of water, 5 parts of alcohol, and in 3.8 parts of

ether at 25° C. (77° F.); very soluble in chloroform and warm alcohol; soluble in 260 parts of water at 80° C. (176° F.); soluble in benzene, carbon disulphide, ethyl acetate, in about 14 parts of oil of turpentine, and in about 12 parts of olive oil; insoluble in glycerin. It melts at 98° C. (208.4° F.), and should leave no residue on ignition. If an alcoholic solution of Cocaine be carefully neutralized with hydrochloric acid, and the solution evaporated to dryness, the residue should respond to the reactions and tests given under *Cocainæ Hydrochloridum*, U. S. The British Pharmacopœia gives the following description and tests: "Colorless monoclinic prisms which have a bitter taste followed by a sensation of tingling and numbness. It melts at 204.8° to 208.4° F. (96° to 98° C.). Almost insoluble in water, insoluble in glycerin, soluble in 10 parts of alcohol (90 per cent.), in 4 parts of ether, in $\frac{1}{2}$ part of chloroform, in 12 parts of olive oil, and in 14 parts of oil of turpentine. Its solution in water acidulated with hydrochloric acid, and the dry salt obtained on evaporating this solution, afford the reactions mentioned under 'Cocainæ Hydrochloridum.' Its solution in water acidulated with nitric acid yields no reaction with the tests for chlorides or sulphates."

Uses.—(See p. 371.) Various salts of the alkaloid have been used in medicine. *Cocaine borate* has been recommended for ophthalmological uses. *Cocaine hydriodide*, $C_{17}H_{21}NO_4 HI$, which occurs in colorless crystals only moderately soluble in water, has been especially recommended by R. Marcus as being suitable for use by cataphoresis for the production of anesthesia. For medicinal uses see *Coca*.

Dose, one-eighth to one-fourth grain (0.008 to 0.016 Gm.).

COCAINÆ HYDROCHLORIDUM.

U. S., Br.

COCAINE HYDROCHLORIDE [*Cocainæ Hydrochloras*, Pharm. 1890, *Cocaine Hydrochlorate*]

(cō-că-y'næ hÿ-drō-phlō'rj-dŭm)

$C_{17}H_{21}NO_4 \cdot HCl = 337.10$

"The neutral hydrochloride [$HCl \cdot C_8H_{13}(C_6H_5CO)NO \cdot COOCH_3$] of an alkaloid obtained from several varieties of *Coca*." U. S. "The hydrochloride, $C_{17}H_{21}NO_4 \cdot HCl$, of an alkaloid obtained from the leaves of *Erythroxylum Coca*, Lam., and its varieties." Br.

Hydrochlorate of Cocaine; Chlorhydrate de Cocaine, Fr. Cod.; Cocainum hydrochloricum, P. G.; Cocainhydrochlorid, G.; Cloridrato di cocaina, It.

Preparation.—Cocaine hydrochloride may be made "by agitating with ether an aqueous solution of an acidulated alcoholic extract of coca made alkaline with carbonate of sodium; separating and evaporating the ethereal liquid; purifying the product by repeating the treatment

with acidulated water, carbonate of sodium, and ether; decolorizing; neutralizing with hydrochloric acid, and recrystallizing." Br. (1885). It is also made by dissolving cocaine in ether or petroleum benzin, and passing dry hydrochloric acid gas into the solution, when the hydrochloride will separate, this may then be dissolved in alcohol and recrystallized. For physiological and medicinal properties, see *Coca*.

Properties.—It is officially described as in "colorless, transparent, monoclinic prisms, flaky, lustrous leaflets or a white crystalline powder; permanent in the air, containing no water of crystallization; odorless; of a saline, slightly bitter taste, and producing on the tongue a tingling sensation followed by numbness of several minutes' duration. Soluble in 0.4 part of water, 2.6 parts of alcohol, and in 18.5 parts of chloroform at 25° C. (77° F.); soluble in 0.1 part of water at 80° C. (176° F.), and in 1.4 parts of alcohol at 60° C. (140° F.); insoluble in benzene, petroleum benzin, and ether. It melts at about 189.9° C. (373.8° F.). Minute quantities of impurities may reduce the melting point to 180° C. (356° F.) or less. It leaves no residue on incineration. Its aqueous solution is neutral to litmus paper, and is levogyrate. If silver nitrate T.S. be added to the aqueous solution of the salt (1 in 100), a white precipitate is produced, which is insoluble in nitric acid. On adding 5 drops of a solution of chromium trioxide (1 in 20) to 5 Cc. of a solution of Cocaine Hydrochloride (1 in 50), a yellow precipitate will be produced, which redissolves on shaking; on now adding 1 Cc. of hydrochloric acid, a permanent, orange-colored, crystalline precipitate will be formed. On adding a solution of potassium chromate (1 in 20) to a hydrochloric acid solution of the salt, orange-yellow leaflets of cocaine chromate are precipitated. If mercuric chloride T.S. be added to an aqueous solution of the salt, a white flocculent precipitate is produced. Cocaine Hydrochloride is not colored by cold sulphuric acid, but if a crystal be heated with sulphuric acid, in a test-tube, vapors are produced, from which benzoic acid is deposited on cooling. If three drops of palladium chloride T.S., with 3 Cc. of chlorine water, be added to 3 drops of an aqueous solution of the salt (1 in 20), a red precipitate is produced. When 0.01 Gm. of the salt is dissolved in 2 drops of water, the addition of 1 Cc. of a solution of potassium permanganate (1 in 30) produces a violet precipitate, which appears brownish-violet when collected on a filter. A crystal of the salt dissolved in alcohol yields when stirred with a piece of potassium hydroxide an odor of ethyl benzoate. If 0.1 Gm. of the salt be dissolved in 5 Cc. of distilled water containing 3 drops of diluted sulphuric acid, the addition to this solution of 3 drops of tenth-normal potassium permanganate V.S. will produce a violet color, which should not fade in half an hour (limit of *cinnamyl-cocaine*). If 0.1 Gm. of the salt be

dissolved in 85 Cc. of cold distilled water, in a beaker, and 4 drops of ammonia water added, and the solution stirred vigorously for fifteen minutes, with occasional rubbing of the sides of the beaker with a stirring rod, a crystalline precipitate of cocaine should be formed, and the supernatant liquid should be perfectly clear (limit of *isatropyl-cocaine*). The presence of 0.5 percent. of *isatropyl-cocaine* will prevent the formation of nearly all of the precipitate, and will cause the supernatant liquid to be opalescent." *U. S.*

The British Pharmacopœia gives the following tests: "It melts at 356° to 366.8° F. (180° to 186° C.). Soluble in half its weight of cold water, forming a clear and colorless solution, neutral to *litmus*, and in four times its weight of alcohol (90 per cent.) or of *glycerin*. It is insoluble in *olive oil* and almost insoluble in *ether*. It affords a yellow precipitate with solution of *auric chloride*; a white precipitate with solution of *ammonium carbonate*, and also with solution of *borax*. It dissolves without color in cold *sulphuric* or *nitric acid*, but chars with hot *sulphuric acid*, evolving an agreeable odor, and yielding a crystalline sublimate of benzoic acid. Its aqueous solution yields with solution of *potassium hydroxide* a white precipitate soluble in alcohol or *ether*, with solution of *picric acid* a yellow precipitate becoming crystalline on standing, with test-solution of *mercuric chloride* slightly acidulated with hydrochloric acid, a white precipitate soluble in hot water. Moistened with *nitric acid*, the mixture evaporated to dryness, and a drop of *alcoholic solution of potassium hydroxide* added, a characteristic odor is evolved more or less recalling that of *peppermint*. A solution containing not less than 1 per cent. gives with excess of solution of *potassium permanganate* a copious red precipitate which does not change color within an hour (absence of *cinnamyl cocaine* and *cocamine* or other products derived from cocaine). 0.1 gramme dissolved in 100 cubic centimetres of water and 0.25 cubic centimetre of solution of ammonia added, affords a clear solution, from which a crystalline deposit should gradually separate on stirring (limit of amorphous alkaloid). It should not afford more than the slightest reactions with the tests for sulphates. Dried for twenty minutes at 204° to 212° F. (95.6° to 100° C.) it should not lose more than 1 per cent. of moisture." *Br.*

Dose, of the salts of cocaine, from one-fourth to one grain (0.016 to 0.065 Gm.).

COCHINEAL

(côc'cûs)

cundated female insect, *Coccus Cacti*, *Linn.*, reared on *Nopalea coccinellifera*, *Salm-Dyck*, and on other species of *Nopalea*." *Br.*

Cocconella; *Cochenille*, *Fr. Cod.*; *Scharlachwurm*, *G.*; *Cochinilla*, *Sp.*

Pseudococcus is a genus of hemipterous insects, having the snout or rostrum in the thorax, the antennæ filiform, and the posterior part of the abdomen furnished with bristles. The male has two erect wings, the female is wingless. The *P. cacti* is characterized by its depressed, downy, transversely wrinkled body, its purplish abdomen, its short and black legs, and its subulate antennæ, which are about one-third of the length of the body. (*Rees's Cyclopædia*.) Another species, *C. ilicis*, which inhabits a species of oak, is collected in the mountainous parts of the Morea, in Greece, and used as a dye-stuff in the East, under the name of *kermes*, *chermes*, or *alkermes*. The dried insects are nearly globular, smooth, about the size of a pea, and of a reddish-brown color. They yield a carmine-colored powder, and, with a salt of tin, a fine scarlet-red dye. *Pseudococcus cacti* is found wild in Mexico and Central America, inhabiting different species of Cactus and allied genera of plants, and is said to have been discovered also in some of the West India islands and southern parts of the United States.

In Mexico, particularly in the provinces of Oaxaca and Guerrero, it is an important object of culture. The Indians form plantations of the *nopal* (*Nopalea coccinellifera*, *Salm*, formerly *Opuntia cochinillifera*, *Mills*), upon which the insect feeds and propagates. During the rainy season, a number of the females are preserved under cover, upon the branches of the plant, and, after the cessation of the rains, are distributed upon the plants without. They perish quickly after having deposited their eggs. These, hatched by the heat of the sun, give origin to innumerable minute insects, which spread themselves over the plant. The males, of which, according to Ellis, the proportion is not greater than one to one hundred or two hundred females, being provided with wings and very active, approach and fecundate the latter. After this period, the females, which before moved about, attach themselves to the leaves, and increase rapidly in size; so that, in the end, their legs, antennæ, and probosces are scarcely discoverable, and they appear more like excrescences on the plant than distinct animated insects. They are now gathered for use, by detaching them by means of a blunt knife, a quill, or a feather, a few being left to continue the race. They are destroyed either by dipping them, enclosed in a bag, into boiling water or by the heat of a stove. In the former case they are subsequently dried in the sun. The males, which are smaller than the full grown females, are not collected. It is said that of the wild insect there are six generations every year, furnishing an equal number of crops; but the domestic is collected only three times annually, the propagation being suspended during the

"The dried female insect, *Pseudococcus cacti* (*Linné*) *Burmeister*." *U. S.* "The dried fe-

rainy season, in consequence of the inability of the insect to support the inclemency of the weather. The insect has been taken from Mexico to the Canary Islands; and very large quantities of cochineal have been delivered to commerce from the island of Teneriffe.¹ Its culture is said to have proved successful in Java and Algeria, but unprofitable in Spain.²

Cochineal is defined in the U. S. Pharmacopœia as follows: "About 5 Mm. long, somewhat oblong and angular in outline, flat and concave beneath, convex above; externally purplish-gray or purplish-black; transversely wrinkled; easily pulverizable, yielding a dark red powder; odor faint; taste slightly bitter. The coloring matter is soluble in water, alcohol, or ammonia water, slightly soluble in ether, insoluble in fixed and volatile oils; alkalis change the color to purple. Ash not more than 6 percent." U. S.

As found in commerce, the finer cochineal, *grana fina* of Spanish commerce, is in irregularly circular or oval, somewhat angular grains, about one-eighth of an inch in diameter, convex on one side, concave or flat on the other, and marked with several transverse wrinkles. Two varieties of this kind of cochineal are known to the druggist, distinguished by their external appearance. One is of a reddish-gray color, formed by an intermixture of the dark color of the insect with the whiteness of a powder by which it is almost covered, and with patches of a rosy tinge irregularly interspersed. From its diversified appearance, it is called by the Spaniards *cochinilla jaspeada*. It is the variety commonly found in commerce. The other, *cochinilla renegrada*, or *grana nigra*, is dark-colored, almost black, with only a minute quantity of the whitish powder between the wrinkles. The two are distinguished in our markets by the names of *silver grains* and *black grains*. Some suppose the difference to arise from the mode of preparation, the gray cochineal consisting of the insects destroyed by a dry heat; the black, of those destroyed by hot water, which removes the external whitish powder; it is also said that cochineal is blackened by placing the insects with black sand in a bag and swinging backward and forward until some of the juice exudes. According to Faber, who derived his information from a merchant residing in the neighborhood where the cochineal is collected, the silver grains consist of the impregnated female just before she has laid

her eggs; the black, of the female after the eggs have been laid and hatched. (*A. J. P.*, xviii. 47.) There is little or no difference in their quality.³ Another and much inferior variety is the *grana sylvestra*, or wild cochineal, consisting partly of very small separate insects, partly of roundish or oval masses, which exhibit, under the microscope, minute and apparently new-born insects, enclosed in a white or reddish cotton-like substance. It is scarcely known in our drug market.

Cochineal has a faint heavy odor and a bitter, slightly acidulous taste. Its powder is of a purplish-carmine color, tinging the saliva intensely red. According to Pelletier and Caventon, it consists of a peculiar coloring principle, a peculiar animal matter constituting the skeleton of the insect, stearin, olein, an odorous fatty acid, and various salts. Tyrosin has also been found by De la Rue, and its presence in cochineal confirmed later by von Miller and Rohde. (*Ber. d. Chem. Ges.*, xxvi. 2660.) It was also analyzed by John, who called the coloring principle *cochinilin*. It is, however, universally known now as *carminic acid*. Hlasiwetz and Grabowski (*Ann. Ch. Ph.*, 141, 329) gave it the formula $C_{17}H_{18}O_{10}$, and considered it to be a glucoside, which was decomposed by boiling with diluted sulphuric acid into a non-fermentable sugar and *carmine red*, $C_{11}H_{12}O_7$. The incorrectness of this view has, however, been demonstrated by von Miller and Rohde (*loc. cit.*), who have shown that the purified carminic acid is a dioxymethyl- α -naphthoquinone of the formula $C_{12}H_{10}O_7$, or the double formula $C_{24}H_{22}O_{14}$, and that the carmine red is identical with it. Schunk and Marchlewski (*Ber. d. Chem. Ges.*, xxvii. 2979) have confirmed these results of von Miller and Rohde, and have shown that the reason that the carminic acid as freshly extracted from the cochineal gave the apparent glucoside reaction was that it is impure. They prepared the pure crystallized carminic acid, its anilide, and identified its character as a naphthoquinone derivative. (Recent writers, without modifying the formula above given, have classified carminic acid as a derivative of hydriodene, C_8H_{10} .) It shows no sharp melting point, beginning to decompose at 130° C. Carminic acid is of a brilliant purple-red color, unalterable in dry air, is very soluble in water, soluble in cold and more so in boiling alcohol, insoluble in ether, and without nitrogen. It is obtained by macerating cochineal in ether, and treating the residue with successive portions of boiling alcohol, which on cooling deposits a part of the carminic acid, and yields the remainder by spontaneous evaporation. It may be freed from a small proportion of adhering

¹ Various species of *Opuntia* are adapted to the support of the cochineal insect, especially plants which are very juicy, with few thorns and a thick skin. It is the *O. Ficus indica* which is chiefly cultivated in Teneriffe, the dry but hot climate of which is peculiarly adapted to the growth both of the plant and the insect. For an account of the mode of rearing the cochineal insect in the Canary Islands, see *P. J.*, Sept. 1871; in Central America, see *A. J. P.*, 1873, 30; *N. R.*, 1880, 175; in Guatemala, see *Ph. Era*, 1893, 227.

² In Asia Minor, in the vicinity of Oushak, are great quantities of an insect, closely resembling the *Coccus* cacti, which feeds on a species of *Cistus*; but it is unknown whether any quantity has been introduced into general commerce. (*A. J. P.*, xxxv. 455.)

³ *Cake cochineal* is the name given to a variety of the drug produced in Argentina. A specimen examined by Stark was in flat cakes about one-fourth of an inch thick, and, under the microscope, was seen to consist chiefly of the cochineal insect, mixed with small portions of the thorns and epidermis of the cactus, in consequence of careless gathering. It is inferior for dyeing purposes to the ordinary variety. (*P. J.*, xlv. 346.)

fatty matter by dissolving it in official alcohol and then adding an equal quantity of ether. The pure carminic acid is deposited in the course of a few days. Chlorine readily destroys the carminic acid, and nascent hydrogen reduces it to a leuco body, which again becomes red on exposure to the air. Liebermann found that the coating of the silver cochineal consisted of a peculiar wax, which he named *coccerin*, $\text{C}_{30}\text{H}_{50}(\text{C}_{21}\text{H}_{31}\text{O}_3)_2$; this is soluble in benzene, but nearly insoluble in ether. (*P. J.*, 1885, 186; from *Ber. d. Chem. Ges.*) The aqueous infusion of cochineal is of a violet-crimson color, which is brightened by the acids and deepened by the alkalis. The coloring matter is readily precipitated. The salts of zinc, bismuth, and nickel produce a lilac precipitate, and those of iron a dark purple approaching to black. The salts of tin, especially the nitrate and the chloride, precipitate the coloring matter of a brilliant scarlet, and form the basis of those splendid scarlet and crimson dyes which have rendered cochineal so valuable in the arts. With alumina the coloring matter forms the pigment called *lake*. The finest lakes are obtained by mixing the decoction of cochineal with fresh gelatinous alumina.

The pigment called *carmine* is the coloring matter of cochineal precipitated from the decoction by acids, the salts of tin, etc., or by animal gelatin, and when properly made is of the most intense and brilliant scarlet. Cochineal-carmine requires for its production a decoction of cochineal itself, and not of carminic acid, the nitrogenized matters being essential to its formation. Liebermann (*Ber. d. Chem. Ges.*, xviii. p. 1971) considers cochineal carmine to be no ordinary compound of a coloring matter with alumina, but to be an alumina albuminate of the carmine coloring matter comparable in some respects to the product from alizarin and alumina with "Turkey-red oil." (See *C. D.*, 1893, 199; *Zeit. angew. Chem.*, 1894.) J. J. Hess proved that if fatty matters found in cochineal were removed by treatment with alcohol, a much more brilliant carmine could be produced. He found in Guatemala cochineal 17 per cent. of a crystalline stearopten, in Java cochineal 7 per cent., and in Canary cochineal 18 per cent. (Dingler, *P. J.*, 235, 88; *N. R.*, 1880, 338.) The degree of coloring power in cochineal may be approximately measured by the decolorizing effect produced by solution of potassium permanganate. For a method of applying this process, the reader is referred to a paper by J. M. Merriek of Boston, in *A. J. P.*, 1871, 263; from *Amer. Chem.*, April, 1871. The Br. Pharm. requires that when cochineal is macerated in water no insoluble powder shall be separated, and that when incinerated with free access of air it shall yield not more than 6 per cent. of ash.

Cochineal has been adulterated by causing certain heavy substances, such as powdered tale, lead carbonate, and barium sulphate, by shaking in a bag or otherwise, to adhere, by

means of some glutinous material, to the surface of the insects, and thus increase their weight. Cochineal yields 1.5 per cent. of ash. Five specimens of the drug have been examined, which left in their ashes respectively 8, 12, 16, 18, and 25 per cent. of the salt of barium. (*A. J. P.*, 1870, p. 220.) The fraud may be detected by the absence, under the microscope, of a woolly appearance which characterizes the white powder upon the surface of the unadulterated insect. Metallic lead, which is said frequently to exist in fine particles in the artificial coating, may be discovered by powdering the cochineal and suspending it in water, when the metal will remain behind. Grains of a substance artificially prepared to imitate the dried insect have been mixed with the genuine in France. A close inspection will serve to detect the difference. (*J. P. C.*, 3e sér., ix. 110.) Vermilion and chrome-red (lead dichromate) are said also to have been largely used in the adulteration of carmine, to the extent sometimes of 60 or even 70 per cent. (*P. J.*, 1860, p. 547.) There can be no difficulty in detecting them by the appropriate tests. Starch has been used, according to Maisch, for the same purpose in the United States, and in one specimen he found 57.14 per cent. (*A. J. P.*, xxxiii. 18.) Artificial cochineal, prepared by coloring exhausted cochineal powder with rosaniline and forming it into grains has been found in commerce. It may be recognized by the facility with which it forms a paste with water.

The importations of cochineal have diminished, owing to the gradual replacement of this dye by the newer azo colors. In 1889, 550,000 lbs. were brought into the United States; in 1902, 1903, and 1904, the importations were 140,756 lbs., 114,326 lbs., and 162,395 lbs., respectively. The reduction in price has been such that at present the production in the Canaries is said not to be remunerative.

Uses.—Cochineal is supposed by some to possess anodyne properties, but is probably useless. In pharmacy it is employed to color tinctures and tooth powders. To infants with *whooping cough*, cochineal in substance is given in the *dose* of about one-third of a grain (0.021 Gm.) three times a day. The *dose*, of a tincture (one part in ten parts of diluted alcohol), is for an adult from twenty to thirty minims (1.3 to 1.8 Cc.). In *neuralgia*, Sauter gave half a tablespoonful (7.5 Cc.) with asserted cure.

CODEINA. *U. S.*, *Br.*

CODEINE

(cō-dē-ī'nā)

"An alkaloid $[\text{C}_{17}\text{H}_{18}(\text{CH}_3)\text{NO}_3 + \text{H}_2\text{O}]$ obtained from Opium, or prepared from mor-

phine by methylation. It should be kept in well-stoppered, amber-colored vials." *U. S.* "An alkaloid, $C_{17}H_{19}(CH_3)NO_3 \cdot H_2O$, obtained from opium or from morphine." *Br.*

Codeina, Methyl-morphine, Codeia; Codeinum, Codeïne, *Fr. Cod.*; Codein, Kodein, *G.*; Codeina, *It., Sp.*

Preparation.—Codeine¹ was discovered in 1832 by Robiquet in morphine hydrochloride prepared according to the process of Gregory. It exists in opium combined like morphine with meconic acid, and is extracted along with that alkaloid in the preparation of the hydrochloride. (See *Morphina*.) When the solution of the mixed morphine and codeine hydrochlorides is treated with ammonia, the former alkaloid is precipitated, and the codeine, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them and yields the codeine in colorless crystals on spontaneous evaporation. Codeine is the methyl derivative of morphine, as shown in the formula $C_{17}H_{19}(CH_3)NO_3$. It may be formed artificially from morphine by treating this latter successively with methyl iodide and fixed alkali. (Grimaux, 1881, *J. Chem. S.*, 44, 358.) According to a recent German patent, codeine is made synthetically by the following process: Morphine, 285 Gm., and nitrosomethylurethane, 132 Gm., are dissolved in 1 kilo. of methyl alcohol. With the solution is mixed, constantly stirring, a solution made by mixing 50 Gm. of potassium hydroxide in 800 Gm. of methyl alcohol. When the reaction is complete, the methyl alcohol is distilled off, and codeine is extracted from the residue with benzene, from which it afterwards separates in characteristic crystals. (*C. D.*, 1898, 237.)

¹ **Apocodeine**, $C_{15}H_{17}NO_3$.—This alkaloid, discovered in 1869 by Matthiessen and Wright, is made by heating a concentrated solution of zinc chloride with codeine. It is soluble in alcohol, ether, and chloroform; insoluble in water. It gives a reaction similar to that of apomorphine, but is more stable. According to Guinard and Fröhner, apocodeine does not act as an emetic. According to Combemale and Dixon, a moderate dose increases very greatly intestinal peristalsis, and Dixon affirms that the one to two per cent. neutral solution is an efficient laxative in doses of 1 to 2 Cc., when given subcutaneously. As the result of his experiments, Dixon believes that the increase of peristalsis is due to a paralyzing influence on the inhibitory intestinal nerves. He also found that the toxic dose of apocodeine paralyzes the peripheral vasomotor nerves, producing great fall of blood pressure, with, in the beginning, rapid action of the heart, followed by slow pulse, which he believes is due to paralysis of the accelerator nerve endings. The increase of the reflexes in the poisoning, and the strychnine-like convulsions sometimes seen, are attributed by Dixon to an effect on the sensory side of the spinal cord.

Apocodeine hydrochloride has been introduced into commerce as a laxative; it is employed subcutaneously in doses of 2 Cc. of a one per cent. aqueous solution (*P. J.*, 1901, 645).

A second derivative from codeine, isomeric with it in formula, has been obtained by Merck as a by-product in the manufacture of apocodeine and has received the name of pseudocodeine. It differs from codeine in its higher melting point, 182° C. (359.6° F.), and in its property of being instantly precipitated by ammonia, in the form of crystalline needles, not only from cold but likewise from boiling aqueous solutions of its salts. According to Kobert, it resembles codeine in its physiological action.

Properties.—Codeine occurs in "white, or nearly translucent, orthorhombic prisms, octahedral crystals, or a crystalline powder; odorless, and having a faintly bitter taste; slightly efflorescent in warm air. Soluble in 88 parts of water, 1.6 parts of alcohol, 12.5 parts of ether, and 0.66 part of chloroform at 25° C. (77° F.); soluble in 59 parts of water at 80° C. (176° F.), and in 0.92 part of alcohol at 60° C. (140° F.). At 100° C. (212° F.) it loses its water of crystallization, and melts at 154.9° C. (310.8° F.). When heated in an insufficient amount of water for complete solution, it melts to oily drops, which crystallize on cooling. It leaves no residue on incineration. Its aqueous solution is alkaline to litmus paper, and is lœvogyrate. Sulphuric acid (free from nitrous compounds) produces either no color or a slight pinkish tint, which disappears within two minutes, but on heating, a violet color is developed. (The presence of nitrous compounds causes a pink color in the cold). Sulphuric acid containing a trace of ferric chloride produces with Codeine a violet-blue color; sulphuric acid heated, with a drop of nitric acid added, gives a blood-red color; sulphuric acid containing a trace of selenous acid produces a green color, changing rapidly to blue, and then slowly back to grass-green (with morphine it gives a blue color, changing to green, and then to brown); sulphuric acid and Codeine develop no color, but on adding a drop of solution of formaldehyde a violet-blue color is produced (morphine giving an intense purple color). On dissolving a small crystal of potassium ferricyanide in 10 Cc. of water, adding 1 drop of ferric chloride T.S., and then 1 Cc. of Codeine solution (1 in 100), no blue color should be produced at once (absence of morphine). If 1 drop of a diluted nitric acid solution (1 drop in 200 Cc. of water) be added to a solution of 0.03 Gm. of Codeine in 2 Cc. of sulphuric acid, a bluish-red tint, gradually changing to blue, will be developed. On sprinkling 0.05 Gm. of Codeine upon 2 Cc. of nitric acid (sp. gr. 1.200) the crystals will turn red, but the acid will acquire only a yellow color (difference from, and absence of, morphine)." *U. S.* "The alkaloid dissolves in an excess of sulphuric acid, forming a colorless solution, a small quantity of which, when gently warmed on a water-bath with 2 drops of solution of ammonium molybdate, or with a trace of ferric chloride or potassium ferricyanide, develops a blue or bluish-black color, which, on the addition of a minute trace of diluted nitric acid, changes to a bright scarlet, becoming orange. Heated to redness in air it yields no ash. Moistened with nitric acid the liquid becomes yellow but not red. A 2 per cent. solution of Codeine in water acidulated with a few drops of hydrochloric acid gives a whitish precipitate with solution of potassium hydroxide, but not with solution of ammonia. A saturated solution of Codeine in water acidulated with hydrochloric acid should give no blue color, but

only gradually a dull green, on the addition of *test-solution of ferric chloride* and a very dilute solution of *potassium ferricyanide* (absence of morphine and other impurities)." *Br.* When added in excess to boiling water, the undissolved portion melts and sinks to the bottom, having the appearance of an oil. It may be separated from morphine by a solution of potassium or sodium hydroxide, which dissolves the morphine and leaves the codeine. It has an alkaline reaction on *test paper*, and combines with acids to form salts, some of which are crystallizable, particularly the nitrate. Its capacity of saturation is almost identical with that of morphine. According to Robiquet, 1 part of hydrochloric acid is saturated by 7.837 of codeine, and by 7.88 of morphine. It is distinguishable, however, from the latter principle by the different form of the crystals, which are octahedral, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, and by not assuming a red color with nitric acid, or a blue one with ferric salts. Tincture of galls precipitates from its solutions a codeine tannate. Crystallized from an aqueous solution, it contains about 6 per cent. of water, which is driven off at 100° C. (212° F.). The crystals obtained from a solution in ether contain no water.

Uses.—Codeine produces in the lower animals marked convulsive symptoms, with heightened reflexes, disturbances of the respiration and rarely tendency to coma. In man the therapeutic dose acts as an uncertain and feeble analgesic and hypnotic, and in large doses may produce marked restlessness. The symptoms of poisoning by it have been vascular excitement, exhilaration, then depression with great anxiety, nausea and vomiting, pale, cool, clammy skin, slight contraction of pupil, and sleeplessness, with slight delirium. In some cases convulsions have been present. In regard to the toxic dose, there is the greatest difference of statement by physicians. Severe poisoning has been reported from the use of four grains, but according to some practitioners five grains have had no effect, and we have frequently given codeine, prepared by Powers and Weightman of Philadelphia, in doses of from six to eight grains without the production of distinct symptoms. It is very evident that commercial codeine has been and probably still is of varying composition, and the results frequently obtained have been produced by adherent alkaloids. Wm. Weightman once informed us that nearly the whole product of their laboratory went to France, where it appeared to be largely used as a calnative drug, free from many of the objections to opium, but in no way comparing with it in power. It has been highly lauded in the treatment of *diabetes mellitus*, and cases of recovery under its use reported. In the grave form of this disorder we have seen it fail to exert any perceptible influence, but the evidence is sufficient to demand a fair trial of the remedy in any

individual case. Medical practitioners often use it to quiet *cough*, to allay *intestinal pain*, and to fulfil various other of the minor narcotic indications for which opium is commonly administered. On account of its frequent contamination with morphine, care should be exercised as to the commencing dose, but no effect at all is to be expected, if the alkaloid be pure, from less than one grain (0.06 Gm.), and this dose may be rapidly increased until some symptoms are produced. It may be given in pill or in syrupy solution.

Dose, one half to two grains (0.032 to 0.13 Gm.).

CODEINÆ PHOSPHAS. U. S., Br.

CODEINE PHOSPHATE

(cō-dē-ī'næ phōs'phās)

"The phosphate $[\text{PO}(\text{OH})_2(\text{C}_{17}\text{H}_{19}(\text{CH}_3)\text{NO}_3) + 2\text{H}_2\text{O}]$ of an alkaloid obtained from Opium, or prepared from morphine by methylation. It should be kept in well-stoppered, amber-colored vials." *U. S.* "The phosphate, $(\text{C}_{17}\text{H}_{19}(\text{CH}_3)\text{NO}_3 \cdot \text{H}_3\text{PO}_4)_2 \cdot 3\text{H}_2\text{O}$, of an alkaloid obtained from opium or from morphine." *Br.*

Phosphate de Codéine, *Fr.*; Codeinum phosphoricum, *P. G.*; Kodeinphosphat, *Phosphorsaures Kodein*, *G.*

This salt is official for the first time in the U. S. and *Br.* Pharmacopœias; it has been introduced because of its easy solubility and stability; it may be made by dissolving 1 part of codeine in 1.25 parts of 25 per cent. phosphoric acid (the solution should be slightly acid in reaction); sufficient alcohol is added to precipitate the codeine phosphate. On account of its large percentage of codeine (about 70 per cent.) it is well fitted for hypodermic injections. It occurs in "fine, white, needle-shaped crystals, or a crystalline powder, without odor, and having a bitter taste. It frequently crystallizes with one and a half molecules of water of crystallization. Soluble in 2.25 parts of water, 261 parts of alcohol, 1340 parts of ether, and in 6620 parts of chloroform at 25° C. (77° F.); soluble in 0.46 part of water at 80° C. (176° F.), and in 97 parts of alcohol at 60° C. (140° F.). At 100° C. (212° F.) it loses all of its water of crystallization; above 200° C. (392° F.) it becomes darker in color, and at 235° C. (455° F.) melts to a brown liquid, which rapidly volatilizes. Its aqueous solution reddens blue litmus paper. If silver nitrate T.S. be added to its aqueous solution, a yellow precipitate is produced, which is soluble in diluted nitric acid and in ammonia water. Sulphuric acid (free from nitrous compounds) produces either no color or a slight pinkish tint, which disappears within two minutes; sulphuric acid containing a trace of ferric chloride produces a violet-

blue color; sulphuric acid containing a trace of selenous acid gives a green color, changing rapidly to blue, and then slowly back to grass-green (with morphine it gives a blue color, changing to green, and then to brown). Sulphuric acid and a drop of solution of formaldehyde produce a violet-blue color (morphine an intense purple). On dissolving a small crystal of potassium ferrieyanide in 10 Cc. of water, adding 1 drop of ferric chloride T.S., and then 1 Cc. of Codeine Phosphate solution (1 in 100), no blue color should be produced at once (absence of *morphine*). If 0.2 Gm. of Codeine Phosphate be dissolved in 5 Cc. of water and 3 Cc. of potassium hydroxide T.S., and the solution shaken out successively with three portions of chloroform (5 Cc. each) the combined chloroform solutions, evaporated to dryness in a tared dish, should yield not less than 0.13 Gm. of codeine." *U. S.* "White crystals which have a slightly bitter taste. It is soluble in 4 parts of *water*, much less soluble in *alcohol* (90 per cent.). A 5 per cent. aqueous solution has a slightly acid reaction, and yields a whitish precipitate with *solution of potassium hydroxide*, but not with *solution of ammonia*. It affords the reactions characteristic of Codeine and of phosphates. It loses its water of crystallization when dried at 212° F. (100° C.), and at a higher temperature melts, forming a yellowish-brown liquid. It should yield no characteristic reaction with the tests for chlorides or sulphates. It should not be colored blue by *test-solution of ferric chloride* (absence of *morphine*)." *Br.*

Uses.—The medicinal properties of codeine phosphate are the same as those of codeine.

Dose, one-half to two grains (0.032 to 0.13 Gm.).

Off. Prep.—Syrupus Codeinæ, *Br.*

CODEINÆ SULPHAS. U. S.

CODEINE SULPHATE

(cō-dē-ī'næ sŭl'phās)

"The sulphate $[SO_2(OH)_2 \cdot (C_{17}H_{19}(CH_3)NO_3)_2 + 5H_2O]$ of an alkaloid obtained from Opium, or prepared from morphine by methylation. It should be kept in well-stoppered, amber-colored vials." *U. S.*

Codeinum sulfuricum; Sulfate de Codéine, *Fr.*; Kodeinsulfat, Schwefelsaures Kodein, *G.*

Preparation.—Codeine sulphate may be made by dissolving codeine in warm water, adding sufficient sulphuric acid to neutralize, evaporating and crystallizing; 16.71 Gm. of sulphuric acid of official strength will be required to neutralize 100 Gm. of codeine.

Properties.—Codeine sulphate is officially described as in "long, glistening, white, needle-

shaped crystals, rhombic prisms, or a crystalline powder, efflorescing in the air, odorless, and having a bitter taste. Soluble in about 30 parts of water, and 1035 parts of alcohol at 25° C. (77° F.); insoluble in chloroform and ether; soluble in 6.25 parts of water at 80° C. (176° F.), and in 340 parts of alcohol at 60° C. (140° F.). The salt loses its water of crystallization at 100° C. (212° F.); chars, decomposes, and partially volatilizes above 200° C. (392° F.), without melting; the residue melts at about 278° C. (532.4° F.). Its aqueous solution is neutral to litmus paper. If barium chloride T.S. be added to an aqueous solution of the salt, a white precipitate is produced, which is insoluble in hydrochloric acid. Sulphuric acid (free from nitrous compounds) produces either no color or a slight pinkish tint, which disappears within two minutes, when added to Codeine Sulphate, but on heating, a violet color is produced; sulphuric acid heated, with a drop of nitric acid added, gives a blood-red color; sulphuric acid containing a trace of selenous acid produces a green color, changing rapidly to blue, and then slowly back to grass-green (with morphine sulphate it gives a blue color, changing to green and then to brown); sulphuric acid and Codeine Sulphate give no color, but on adding a drop of solution of formaldehyde, a violet-blue color is produced (morphine sulphate yielding an intense purple color). If 1 drop of a diluted nitric acid solution (1 drop in 200 Cc. of water) be added to 2 Cc. of a solution of 0.1 Gm. of Codeine Sulphate in 6 Cc. of sulphuric acid, a bluish-red tint, gradually changing to blue, will be developed. On dissolving a small crystal of potassium ferrieyanide in 10 Cc. of water, adding 1 drop of ferric chloride T.S., and then 1 Cc. of Codeine Sulphate solution (1 in 100), no blue color should be produced at once (absence of *morphine*)." *U. S.*

Uses.—The medicinal properties of this salt are those of the alkaloid codeine.

Dose, one-half to two grains (0.032 to 0.13 Gm.).

COLCHICI CORMUS. U. S., Br.

COLCHICUM CORM [Colchici Radix, *Pharm.* 1890,

Colchicum autumnale, Willd., *Sp. Plant.* ii. 272; Woodv., *Med. Bot.*, p. 759, t. 258.—This species of *Colchicum*, often called *meadow saffron*, is a perennial bulbous plant, the leaves of which appear in spring, and the flowers in autumn. Its manner of growth is peculiar, and deserves notice as connected in some measure with its medicinal efficacy. In the latter part of summer, a new bulb, or *corm*, as the part is now called, begins to form at the lateral inferior portion of the old one, which receives the young offshoot in its bosom and embraces it half round. The new plant sends out fibres from its base, and is furnished with a radical spathe, which is cylindrical, tubular, cloven at top on one side, and half under ground. In September, from two to six flowers, of a lilac or pale-purple color, emerge from the spathe, unaccompanied by leaves. The corolla consists of a tube five inches long, concealed for two-thirds of its length in the ground, and of a limb divided into six segments. The flowers perish by the end of October, and the rudiments of the fruit remain under ground until the following spring, when they rise upon a stem above the surface, in the form of a three-lobed three-celled capsule. The leaves of the new plant appear at the same time, so that in fact they follow the flower instead of preceding it, as might be inferred from the order of the seasons in which they respectively show themselves. The leaves are radical, spear-shaped, erect, numerous, about five inches long, and one inch broad at the base. In the meantime, the new corm has been increasing at the expense of the old one, which, having performed its appointed office, perishes; while the former, after attaining its full growth, sends forth shoots, and in its turn decays. The old corm in its second spring, and a little before it perishes, sometimes puts forth one or more small corms, which are the sources of new plants.

C. autumnale is a native of the temperate parts of Europe and of Northern Africa, growing in moist pastures and meadows. Attempts have been made to introduce its culture into this country, but with no great success, though small quantities of the corm, of apparently good quality, have entered commerce. The flowers possess virtues similar to those of the corm and are recognized by the French Codex.

COLCHICI CORMUS.—The medicinal virtue of the corm depends much upon the season at which it is collected. Early in the spring it is too young to have fully developed its peculiar properties, and late in the fall it has become exhausted by the nourishment afforded to the new plant. The proper period for its collection is from the early part of June, when it has usually attained perfection, to the middle of August, when the offset appears.¹ It may be owing, in part, to this inequality at different seasons that entirely opposite reports have been given of its powers. Krapf ate whole corms without inconvenience; Haller found them entirely void of taste and acrimony, and we are told that in Carniola the peasants use them as food with impunity in the autumn. On the other hand, there can be no doubt of its highly irritating and poisonous nature, when fully developed, under ordinary circumstances. Perhaps soil and climate may have some influence in modifying its character.

The corm is often used in the fresh state in the countries where it grows, as it is apt to be injured in drying, unless the process is carefully conducted. The usual plan is to cut the corm, as soon as possible after it has been dug up, into thin transverse slices, which are spread out separately upon paper or perforated trays and dried with a moderate heat. The reason for drying it quickly after removal from the ground is that it otherwise begins to vegetate, and a change in its chemical nature takes place; and such is its retentiveness of life that, if not cut in slices, it is liable to undergo a partial vegetation even during the drying process. Houlton recommends that the corm be stripped of its dry coating, carefully deprived of the bud or young bulb, and then dried whole. It is owing to the high vitality of the bud that the corm is so apt to vegetate. During desiccation there is great loss of weight, 70 per cent. being the average for a number of years in the laboratory of Allen & Hanburys, in London.

Properties.—The recent bulb or corm of *C. autumnale* resembles that of the tulip in shape and size, and is covered with a brown membranous coat. Internally it is solid, white and fleshy, and, when cut transversely, yields, if mature, an acrid milky juice. There is often a small lateral projection from its base, which is the bud for the development of a new plant; this bud is frequently broken off in drying. When dried, and deprived of its external membranous covering, the corm is of an ash-brown color, convex on one side, and somewhat flattened on the other, where it is marked by a

¹ Christian, however, has found the roots collected in April to be more bitter than those gathered in July, and conjectures that the common opinion of their superior efficacy at the latter season may not be well founded. Schroff states, as the result of his observation, that the autumnal root is much stronger than that dug in the summer. (See *A. J. P.*, xlix. 324.)

deep groove extending from the base to the summit. As found in commerce, it is always in the dried state, sometimes in segments made by vertical sections of the bulb, but generally in transverse circular slices, about the eighth or tenth of an inch in thickness, with a notch at one part of their circumference. "Ovoid, somewhat compressed laterally, and with a groove on one side, or more commonly in transverse, reniform, or longitudinal, ovate slices; externally brownish and finely wrinkled; internally whitish, with numerous circular groups of fibrovascular bundles, giving the surfaces of the transverse sections a papillose appearance; fracture short, mealy; odor slight; taste sweetish, bitter, and somewhat acrid." *U. S.* The cut surface is white and of an amylaceous aspect. Examined with the microscope, the corm is seen to be composed of large irregular cells, full of ovoid, angular, sometimes compound, starch grains, and interspersed with spiral vessels in vascular bundles. The odor of the recent corm is said to be hirine. It is diminished, but not lost, by drying. The taste is bitter, hot, and acrid. Wine and vinegar extract all its virtues.

Colchicum corm contains the alkaloid *colchicine*, $C_{22}H_{25}NO_6$, which was made official in the *U. S. P.* (8th Rev.); see *Colchicina*. Colchicine is the active principle and as much as 0.4 per cent. is found in good specimens of the corm; the official requirement is that not less than 0.35 per cent. shall be present, to be determined by the following assay:

Assay of Colchicum Corm. *U. S.* (8th Rev.)—"Colchicum Corm, in No. 60 powder, ten grammes; Ether, Chloroform, Alcohol, Ammonia Water, Distilled Water, each, a sufficient quantity. Introduce the Colchicum Corm into a 200 Cc. Erlenmeyer flask, and add to it 100 Cc. of a mixture of 77 Cc. of ether, 25 Cc. of chloroform, 8 Cc. of alcohol, and 3 Cc. of ammonia water, insert the stopper securely, and macerate, with frequent shaking, for twelve hours (or preferably for four hours in a mechanical shaker). Filter a sufficient quantity of the liquid into a measuring cylinder until 50 Cc. of filtrate (representing 5 Gm. of Colchicum Corm) have been obtained; then transfer this to a beaker or dish, and evaporate it nearly to dryness by applying a gentle heat. Dissolve the residue in 10 Cc. of ether, add 5 Cc. of water, stir well, and heat gently until the ether has evaporated. After cooling, filter the aqueous solution into a small separator, retaining the insoluble matter as much as possible in a little ether, add 5 Cc. of water, and proceed as before. Wash the container and filter with a little water, and shake the combined aqueous solutions well for one minute with 15 Cc. of chloroform. Draw off the chloroform, after perfect separation, into a beaker, and again shake out the aqueous liquid successively with three portions of 10 Cc. each of chloroform, collecting these solutions in the

beaker. Evaporate the chloroform completely; dissolve the residue in a little alcohol, evaporate the latter, redissolve the residue in 5 Cc. of ether, add 5 Cc. of water, and stir the liquid for a few seconds. Then evaporate the ether on a water-bath containing warm water, and filter the remaining aqueous liquid through a small wetted filter into a separator, washing the dish and filter with 5 Cc. of water, and adding the washings to the separator. Shake out the aqueous liquid with 15 Cc. of chloroform, and when the liquids have separated, draw off the chloroform into a tared flask. Repeat the shaking out successively with three portions of 10 Cc. of chloroform and add each to the tared flask. Evaporate the chloroform completely, dissolve the residue in a little alcohol, evaporate the latter, redissolve the residue in alcohol, evaporate the alcohol as before, and dry the residue at 100° C. (212° F.) until the weight, after cooling, remains constant. The weight of the residue multiplied by 20 gives the percentage of colchicine in the Colchicum Corm." *U. S.*

A. T. Thompson states that the milky juice of fresh colchicum produces a fine blue color if rubbed with the tincture of guaiac, and that the same effect is obtained from an acetic solution of the dried corm. He considered the appearance of this color, when the slices were rubbed with a little distilled vinegar and tincture of guaiac, a proof that the drug was good and had been well dried. J. M. MacLagan has shown that this change of color is produced with the albumen, which is not affected if previously coagulated; so that the value of the test consists simply in proving that the drying has not been effected at a heat above 180° F., or the temperature at which albumen coagulates. A very deep or large notch in the circumference of the slices is an unfavorable sign, as it indicates that the bulb has been somewhat exhausted in the nourishment of the offset. The decoction yields a deep blue precipitate with solution of iodine, white precipitates with lead acetate and subacetate, mercurous nitrate, and silver nitrate, and a slight precipitate with tincture of galls. The value of colchicum is best tested by its bitterness. For method of assaying colchicum, by K. Schwickerath, see *Ph. Rund.*, 1893, 282. Important improvements have been made in the assay by Bredemann. (*Ap. Ztg.*, 1903, 18, Nos. 93, 94, 95.)

COLCHICI SEMEN.—The seeds of the meadow-saffron ripen in summer, and should be collected about the end of July or beginning of August. They never arrive at maturity in plants cultivated in a dry soil or in confined gardens. (Williams.) They are nearly spherical, about the eighth of an inch in diameter, of a reddish-brown color externally, white within, and of a bitter acrid taste. "Subglobular, about 2 Mm. in diameter, very slightly pointed at the hilum; externally reddish-brown, finely pitted; internally whitish;

tough and of almost bony hardness; nearly inodorous; taste bitter and somewhat acid." *U. S.* They are chiefly composed of a gray horny albumen, constituted of very thick-walled cells, and surrounded by a closely adherent testa. The leafless embryo is very small, and is situated close to the surface opposite the strophiole. Williams of Ipswich, England, first brought them into notice in 1820 as superior to the corm. Schroff, however, has found that their activity is inferior to that of the dried corm dug in autumn (*A. J. P.*, xxix. 324). A wine, fluidextract, and tincture of the seeds are directed in the *U. S. Pharmacopœia*. Their dose is slightly less than that of the similar preparations made from the corm.

The *U. S. Pharmacopœia* (8th Rev.) directs that colchicum seed should contain not less than 0.55 per cent. of colchicine, to be determined by the following process:

Assay of Colchicum Seed. *U. S.* (8th Rev.) "Colchicum Seed, in No. 60 powder, *ten grammes*; Ether, Chloroform, Alcohol, Ammonia Water, Distilled Water, each, *a sufficient quantity*. Introduce the Colchicum Seed into a 200 Cc. Erlenmeyer flask, and add to it 100 Cc. of a mixture of 77 Cc. of ether, 25 Cc. of chloroform, 8 Cc. of alcohol, and 3 Cc. of ammonia water, insert the stopper securely, and macerate, with frequent shaking, for twelve hours (or preferably for four hours in a mechanical shaker). Filter a sufficient quantity of the liquid into a measuring cylinder until 50 Cc. of filtrate (representing 5 Gm. of Colchicum Seed) have been obtained; then transfer this to a beaker or dish, and evaporate it nearly to dryness by applying a very gentle heat. Dissolve the residue in 10 Cc. of ether, add 5 Cc. of water, stir well, and heat gently until the ether has evaporated. After cooling, filter the aqueous solution into a small separator, retaining the insoluble matter as much as possible in the beaker or dish. Redissolve the residue in a little ether, add 5 Cc. of water, and proceed as before. Wash the container and filter with a little water, and shake the combined aqueous solutions well for one minute with 15 Cc. of chloroform. Draw off the chloroform, after perfect separation, into a tared flask, and again shake out the aqueous liquid successively with three portions of 10 Cc. each of chloroform, collecting these solutions in the tared flask. Evaporate the chloroform completely; dissolve the residue in a little alcohol, evaporate the latter, redissolve the residue in alcohol, evaporate the alcohol as before, and dry the residue at 100° C. (212° F.) until the weight, after cooling, remains constant. The weight of the residue multiplied by 20 gives the percentage of colchicine in the Colchicum Seed." *U. S.*

Uses.—When taken internally in therapeutic dose, colchicum usually produces no other symptoms than intestinal pains and looseness of the bowels. In some rare cases it is said

to give rise to copious diuresis or diaphoresis instead of purging. When larger amounts are exhibited, the purging is more pronounced, and there may be also vomiting. With these symptoms there may be some depression, which seems to be due to the gastro-intestinal irritation rather than to the direct action of the poison. In an overdose, it may produce dangerous and even fatal effects. Excessive nausea and vomiting, abdominal pains, purging and tenesmus, great thirst, sinking of the pulse, coldness of the extremities, and general prostration, with occasional symptoms of nervous derangement, such as headache, delirium, and stupor, are among the results of its poisonous action. A peculiarity of its influence is that when its dose is increased beyond a certain point there is not a corresponding increase in the rapidity of the fatal issue. This is probably because it kills not by a direct influence upon the heart or the nervous system, but by causing gastro-enteritis. On post-mortem examination the alimentary mucous membrane is found much inflamed.

Colchicum was well known to the ancients as a poison, and is said to have been employed by them as a remedy in gout and other diseases. Störck revived its use among the moderns. He gave it as a diuretic and expectorant in *dropsy* and *humoral asthma*, and on the continent of Europe it acquired considerable reputation in these complaints, but the uncertainty of its operation led to its general abandonment, and it had fallen into almost entire neglect, when Want of London, again brought it into notice by attempting to prove its identity with the active ingredient of the *eau médicinale d'Husson*, so highly celebrated as a cure for gout. In James's Dispensatory, printed in 1747, it is said to be used in gout as an external application. The chief employment of the meadow-saffron is at present in the treatment of *gout*; its action has been attributed to a power of increasing uric acid elimination, but the testimony of investigators is so contradictory that no positive conclusion can be drawn, although the probabilities are that it has no effect on the elimination of uric acid.

In preparing colchicum pharmaceutically, if it be desired to retain the colchicine unchanged, both acids and alkalis should be avoided, especially when heat is employed. Of the official preparations, the fluidextract contains the colchicine as in nature; the acetic extract has a portion at least of colchicine in its composition. In the wines, when kept, the colchicine probably passes gradually into colchicine. But it has not been proved that these latter preparations are in any degree less efficacious remedially, and, in the absence of all experience to the contrary, the inference is that colchicine may have all the powers of colchicine, for the acetic extract, and the wines after being long kept, have often been used in practice, without having been found less effectual than other preparations of colchicum.

Dose, of the dried corm and seed, from two to eight grains (0.13 to 0.52 Gm.), which may be repeated every four or six hours until its effects are obtained.

COLCHICINA. U. S.

COLCHICINE

(eōl-ghī-ā'nā)

"An alkaloid obtained from *Colchicum*. It should be kept in dark amber-colored, well-stoppered vials." U. S.

Colchicine, Fr.; Colchicin, G.

The alkaloid *colchicine*, whose nature was first precisely made out by Geiger and Hesse, has been the subject of much controversy, for an account of which the reader is referred to the seventeenth edition of the U. S. Dispensatory, page 427, foot-note. It is now recognized to be the *methyl ester of acetyl-trimethyl colchicine acid*, and has the formula $\text{C}_{22}\text{H}_{25}\text{NO}_6$. When colchicine is heated with 3 parts of hydrochloric acid for two hours on the water bath, it is decomposed, with the formation of *colchicine acid*, $\text{C}_{16}\text{H}_{15}\text{NO}_5$, and *dime-thyl colchicine acid*, $\text{C}_{18}\text{H}_{19}\text{NO}_5$. When colchicine is boiled with water containing sulphuric acid, it is decomposed thus:

$\text{C}_{22}\text{H}_{25}\text{NO}_6 + \text{H}_2\text{O} = \text{C}_{21}\text{H}_{23}\text{NO}_6 + \text{CH}_3\text{OH}$
the products formed being *colchicine* and methyl alcohol. The colchicine is formed so readily that some of the reactions commonly attributed to colchicine itself are probably due to its decomposition product. Colchicine, which is *aceto-trimethyl colchicine acid*, can also be made synthetically by heating *trimethyl colchicine acid* with acetic anhydride to 100° C. Colchicine has also been built up synthetically from colchicine, sodium methylate, and methyl iodide, which are heated together to 100° C. (Johanny, Zeisel, *Monatshefte*, 9, 868.) Colchicine is soluble in water and alcohol, also in chloroform, benzene, and amyl alcohol. Dragendorff describes it as soluble in ether, but Zeisel as scarcely so. Insoluble in petroleum benzin. It is colored yellow with concentrated sulphuric acid, and blue, turning to brown and yellow, with nitric acid. It forms precipitates with the usual alkaloidal reagents.

Properties.—The U. S. Pharm. (8th Rev.) officially describes colchicine as in "pale yellow leaflets, or a pale yellow, amorphous powder, turning darker on exposure to light, having an odor suggesting damp hay, and a very bitter taste. Soluble in 22 parts of water, 155 parts

of ether, and in 87 parts of benzene at 25° C. (77° F.); soluble in 20 parts of water at 80° C. (176° F.); very soluble in alcohol and chloroform; insoluble in petroleum benzin. After drying over sulphuric acid, it melts if heated to 142.5° C. (288.5° F.). It leaves no residue upon incineration. Its aqueous solution is neutral to litmus paper, levogyrate, and of a yellow color, which is intensified by mineral acids. With Colchicine, sulphuric acid produces a citron-yellow color, which, upon adding a drop of nitric acid, changes to greenish-blue, then to red, and finally to yellow. On adding an excess of potassium hydroxide, the color is changed to red. Ferric chloride T.S., on being added to an aqueous solution of Colchicine, gives no color, but on heating, a brownish-red color is developed, which changes to brownish-black; if ferric chloride T.S. be added to an alcoholic solution of Colchicine, a garnet-red color is at once produced. To 5 drops of an aqueous Colchicine solution, add 5 drops of fuming nitric acid, 5 drops of ferric chloride T.S., and then heat to boiling, when a yellow solution will be formed, changing to olive-green. When cool, shake the liquid with a little chloroform, when the latter will turn ruby-red, and the aqueous solution will remain green. Sulphuric acid containing a fragment of potassium dichromate gives a greenish-blue color, changing to orange." U. S.

Uses.—The alkaloid *colchicine* acts like colchicum, according to Maret and Combemale, in doses of one-twelfth of a grain (0.005 Gm.) producing violent diarrhoea, with diminished urinary secretion; in doses of one-thirty-second of a grain (0.002 Gm.) causing some abdominal disturbance, with increased diuresis. According to J. Sprega, three grains (0.2 Gm.), repeated in three hours, caused violent gastroenteritis, ending in death in thirty-one hours. (*Gazz. d. Ospitali*, Oct. 1890.) *Colchicine salicylate* is a yellow amorphous powder, soluble in water, alcohol, and ether, the dose being one-hundredth of a grain (0.0006 Gm.) every four hours.

Dose, one-hundred and fiftieth to one-hundredth of a grain (0.0004 to 0.0006 Gm.).

COLLODIUM. U. S., Br.

COLLODION

(eōl-lō'dī-ūm)

Collodion, Fr. *Col.*; Collodium, P. G.; Kollodium, G.; Colodio, It.; Collodion, Sp.

* "Pyroxylin, forty grammes [or 1 ounce av., 180 grains]; Ether, seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims]; Alcohol, two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]. To the Pyroxylin, contained in a suitable bottle, add the Ether, and allow it to stand for fifteen minutes; then add the Alcohol, and shake the bottle until the Pyroxylin is dissolved. Cork the bottle well, and set it aside

until the liquid has become clear. Finally, decant the clear portion from any sediment which may have deposited, and transfer it to bottles, which should be well corked and sealed. Keep the Collodium in a cool place, remote from lights or fire." U. S. "Pyroxylin, 1 ounce (Imperial) or 10 grammes; Ether, 36 fl. ounces (Imp. meas.) or 360 cubic centimetres; Alcohol (90 per cent.), 12 fl. ounces (Imp. meas.) or 120 cubic centimetres. Mix the Ether and the Alcohol; add the Pyroxylin; set aside for a few days; should there be any sediment, decant the clear Collodium." Br.

Collodium is a solution of gun cotton. On account of the facility with which ether evaporates, it is the better menstruum for remedial purposes, but gun cotton will not dissolve in that liquid when quite pure, and the addition of strong alcohol is necessary. Formerly the U. S. Pharmacopœia directed that the gun cotton be prepared at the time of making the collodium, giving directions for the purpose, but at the revision of 1870 the process of the British Pharmacopœia was substantially adopted, a formula for the preparation of pyroxylin being given separately in the Pharmacopœia. A process for the preparation of pyroxylin was not introduced into the U. S. Pharmacopœia (8th Rev.), but the British Pharmacopœia still retains a process (see *Pyroxylinum*.) A change has been made, however, in directing the collodium to be decanted from the sediment. In the U. S. P. 1870 the sediment was directed to be re-incorporated with the clear collodium, and the result was the making of a tougher film. This sediment consists of undecomposed filaments of cotton, and these become partially felted as the ethereal liquid evaporates and the film is forming; this direction of the former Pharmacopœia was usually disregarded, although for many purposes the cloudy film is to be preferred.

Acetone has been used as a solvent for pyroxylin and collodium so prepared is on the market.

Properties.—Collodium is a transparent, colorless liquid, of a syrupy consistence and an ethereal odor. When applied to a dry surface, the ether quickly evaporates, and a transparent film is left, having remarkable adhesiveness and contractility. On account of the great volatility of ether, collodium must be kept in bottles well stoppered. When insecurely kept, the liquid thickens and becomes less fit for the use of the surgeon. The thickened liquid sometimes contains acicular crystals. The addition of a mixture of 3 volumes of ether and 1 volume of alcohol will generally restore the collodium to its original condition.

Uses.—Collodium was first applied to the purposes of surgery by J. Parker Maynard¹ of

Boston, when a student of medicine, in January, 1847, although, as pointed out by Kahlbaum, Schoenbein, the discoverer of gun cotton, suggested the surgical use of an ethereal solution in 1846 (*Nat. Drug.*, 1902, 8). It is employed for holding together the edges of incised wounds, for covering ulcers, abraded or diseased surfaces, chilblains, chapped nipples, etc., with an impervious film not acted upon by water, and for encasing parts which require to be kept without relative motion. It is applied brushed over the part, or by means of strips of muslin. In whatever way applied, the solvent quickly evaporates, and leaves the solid adhesive material, which is soluble neither in water nor in alcohol. The rigid film thus formed contracts with a good deal of force. This property adapts collodium for certain purposes, such as drawing together the edges of wounds, exciting pressure on buboes, etc. When, however, the surgeon desires simply to protect a surface, a flexible, non-contracting film is preferable, and the official flexible collodium should be used. Collodium has been variously medicated, and thus made the vehicle of several important medicines for external application. *Iodized collodium* has been proposed by C. Fleming, for the purpose of obtaining the specific effects of iodine in a rapid manner, especially on tumors. It is made by dissolving from ten to twenty grains of iodine in a fluidounce of collodium. Aran has proposed a *ferruginous collodium*, made of equal parts of collodium and tincture of ferric chloride, as a remedy in *erysipelas*. A *caustic collodium* may be prepared by dissolving 4 parts of corrosive sublimate in 30 of collodium. Macke of Sorau, has used this preparation for destroying *nævi materni*. The eschar formed is one or two lines in thickness, and separates in from three to six days, leaving but a trifling cicatrix. (See A. J. P., May, 1858, for formulas in which collodium is made the vehicle of iodine, belladonna, sulphur, etc.) All these medicated collodiums are best applied by means of a camel's-hair brush.²

one or two hours; then pour off the acids, wash the cotton till the washings cease to affect litmus paper, and dry thoroughly. The gummy matter thus formed is now to be dissolved in ether of the sp. gr. about .750, or in a mixture of three parts of pure ether and one part of alcohol of 95 per cent. Two ounces of cotton will make about a pint of collodium. (B. M. S. J., 1866, p. 39.)

² *Pavesi's Styptic Collodium.*—Collodium, 100 parts; phenol, 10 parts; pure tannin, 5 parts; benzoic acid, 3 parts. Agitate till thoroughly mixed. On evaporation it leaves a brown pellicle, adhering strongly to tissues, and effecting instant coagulation of the blood and albumin.

Belladonna Collodium (Collodium Belladonnæ).—Mix 10 fluidounces each of fluidextract of belladonna leaves and ether, and set aside for 12 hours. Decant and dissolve therein 130 grains camphor, 183 grains pyroxylin, 365 grains Canada balsam, 183 grains castor oil. (Naylor.)

Iodoform Collodium is made, according to Moleschott, by dissolving 1 part of iodoform, in fine powder, in 15 parts of flexible collodium. It is recommended for relieving pain caused by gout, and for *orchitis*, *pericarditis*, etc.

Core Collodium (Gesow's) may be made by dissolving 8 grains of extract of Indian hemp in 30 minims of strong alcohol and adding this to a solu-

¹ Maynard recommended the following formula. Take of sulphuric acid of sp. gr. 1.850 two parts, and of nitric acid of sp. gr. 1.450 one part. Mix them, and, having permitted the heat to fall to about 100° F., add raw cotton to saturation. Let it macerate for

COLLODIUM CANTHARIDATUM. U. S. (Br.)

CANTHARIDAL COLLODION [Blistering Collodium]

(côl-lô'di-ûm càn-thâr-î-dă-tûm)

Collodium Vesicans, Br.; Blistering Collodium; Collodium Cantharidale, *s. Vesicans*; Collodium vésicant (cantharidé), *Fr.*; Collodium Cantharidatum, *P. G.*; Spanischfliegen-Kollodium, Blasenziehendes Collodium, *G.*

* "Cantharides, in No. 60 powder, *sixty grammes* [or 2 ounces av., 51 grains]; Flexible Collodium, *eighty-five grammes* [or 3 ounces av.]; Chloroform, a sufficient quantity, to make *one hundred grammes* [or 3 ounces av., 231 grains]. Pack the Cantharides firmly in a cylindrical percolator and gradually pour Chloroform upon it until the powder is exhausted. Recover the Chloroform by distillation from a water-bath and evaporate the residue in a tared evaporating dish on a water-bath, until it weighs *fifteen grammes* [or 231 grains]. Dissolve this in the Flexible Collodium, and set it aside in a securely corked bottle, and in a cool place, to become clear by settling. Finally, pour off the clear portion from any sediment which may have deposited, and transfer it to bottles, which should be well corked and sealed. Keep the Cantharidal Collodium in a cool place, remote from lights or fire." *U. S.*

"Blistering Liquid, 20 *fl. ounces* (Imperial measure) or 200 cubic centimetres; Pyroxylin, $\frac{1}{2}$ ounce (Imp.) or 5 grammes. Add the Pyroxylin to the Blistering Liquid in a stoppered bottle; shake them together until the Pyroxylin is dissolved." *Br.*

The official process does not differ materially from that of the *U. S. P.* 1890. Chloroform is used to extract the cantharidin from the powdered cantharides, by percolation; the chloroform is afterwards recovered by distillation, and the oily residue containing the vesicant is dissolved in the collodium. The efficiency of chloroform as a solvent of cantharidin was demonstrated by Procter. The original process of Ilisch was to exhaust, by percolation, a pound of cantharides, with a mixture consisting of a pound of ether and three ounces of acetic ether, and in two ounces of this liquid to dissolve 25 grains of gun cotton. Procter stated that it had been found more advantageous to exhaust the flies with ether, distil off the ether, and mix the oily residue with collodium already prepared of the proper consistence (*A. J. P.*, xxiv. 303); but at the present time owing to the cheapness of chloroform and its advan-

tage over the very inflammable and dangerous ether the official process is greatly preferred. Charles S. Rand (*A. J. P.*, xxii. 18) states that Ilisch's preparation, made with double the proportion of ether, vesicates equally well, and proposes the addition of about 1 per cent. of Venice turpentine, which he has found to prevent the disagreeable and sometimes painful contraction of the collodium upon drying. The preparation may be kept indefinitely, without change, in an opaque glass stoppered bottle, but on exposure to the light, the greenish coloring matter of the flies bleaches, and the liquid becomes yellowish. *Cantharidized collodium* may be made from cantharidin by dissolving four grains of cantharidin in one thousand grains of flexible collodium.

Cantharidal collodium is a very convenient epispastic remedy. It may be applied to the surface by means of a camel's-hair brush, and after the evaporation of the ether, which takes place in less than a minute, may be reapplied if the surface should not be well covered. It produces a blister in about the same time as the ordinary cerate, and has the advantages that it is applied with greater facility, is better adapted to cover uneven surfaces, and retains its place more certainly. According to Rand, if the evaporation of the ether be restrained by a piece of oiled silk immediately after its application, it will act much more speedily.

COLLODIUM FLEXILE. *U. S., Br.*

FLEXIBLE COLLODION

(côl-lô'di-ûm flêx'i-lê)

Collodium élastique, *Fr.*; Collodium elasticum, *P. G.*; Elastisches Collodium, Kollodium, *G.*; Collodio elastico, *It.*; Collodion elastico, *Sp.*

* "Collodium, *nine hundred and twenty grammes* [or 32 ounces av., 198 grains]; Canada Turpentine, *fifty grammes* [or 1 ounce av., 334 grains]; Castor Oil, *thirty grammes* [or 1 ounce av., 25 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Weigh the ingredients, successively, into a tared bottle, and mix them thoroughly. Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire." *U. S.*

"Collodium, 12 *fl. ounces* (Imperial measure) or 480 cubic centimetres; Canada Turpentine, $\frac{1}{2}$ ounce (Imp.) or 20 grammes; Castor oil, $\frac{1}{4}$ ounce (Imp.) or 10 grammes. Mix." *Br.*

The contractility of the collodium film has long been felt as a drawback to its use simply for the purposes of protection. C. S. Rand of Philadelphia, proposed to obviate this by dissolving one part of gun cotton and three of Venice turpentine in twenty parts of ether. To give more flexibility to the film, Sourisseau of Kaiserberg, suggested the addition of one part of elemi to twelve of collodium. According to Startin of London, opacity and elasticity may be imparted at the same time by adding from half a drachm to a drachm of lard, or

tion of 45 grains of salicylic acid in 300 minims of flexible collodium. This is applied with a camel's-hair brush.

Benzoinated collodium (Collodium Benzoinatum) is made by mixing 60 Cc. of compound tincture of benzoin, with 5 Cc. of glycerin and 120 Cc. of collodium.

Croton Oil Collodium may be made by mixing equal weights of croton oil and flexible collodium. (*Report on Revision of U. S. Pharm., A. Ph. A., 1880.*)

some similar fatty matter, previously dissolved in ether, to an ounce of collodion. The qualities of softness and elasticity may also be given by combining collodion with castor oil, in the proportion of thirty parts to two, agreeably to the plan of Guersant, who found it useful, thus modified, in erysipelas; and the proportion of castor oil may be increased if thought desirable. This is the method preferred by the French Codex. An elastic collodion, somewhat similar, in which, besides castor oil, Venice turpentine and white wax are ingredients, has been proposed by E. Laurus. (*P. J.*, xii. 303.) According to Cap and Garot, the most successful way for obtaining an elastic collodion is to mix two parts of glycerin with one hundred of collodion. *Glycerized collodion* is exceedingly supple, does not crack and scale off from the skin, and accommodates itself to the motions of the part. In order to imitate the color of the skin, an ethereal tincture of turmeric or saffron may be added, so as to produce the desired tint. Meller has proposed a solution of shellac in highly rectified alcohol, so as to have a gelatinous consistence, as a substitute for collodion. Of all these plans, probably that followed in the official directions is the best. Tournie recommends, in superficial *cervical adenitis* with redness, painting the part with several layers of flexible collodion every two days. (*M. T. G.*, 1874, p. 540.)

Off. Prep.—Collodium Cantharidatum, *U. S.*

COLLODIUM STYPTICUM. *U. S.*

STYPTIC COLLODION

(cōl-lō'dī-ŭm stŭp'tī-cŭm)

Collodium Hæmostaticum, Styptic Colloid, Xylo-styptic Ether; Collodion styptique, Collodion au tannin, *Fr.*; Tannin Collodium, *G.*

* "Tannic Acid, twenty grammes [or 308.6 grains]; Alcohol, five cubic centimeters [or 81 minims]; Ether, twenty-five cubic centimeters [or 406 minims]; Collodion, a sufficient quantity, to make one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Introduce the Tannic Acid, Alcohol and Ether into a graduated bottle, agitate the mixture until the Tannic Acid is thoroughly incorporated and partially dissolved, then add enough Collodion to make up the volume to one hundred cubic centimeters [or 3 fluidounces, 183 minims], and shake occasionally, until the Tannic Acid is completely dissolved. Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire." *U. S.*

This collodion is a modification of the *styptic colloid* of B. W. Richardson of London (*P. J.*, 1867, p. 29), a preparation which has had considerable use, particularly in hospitals. Experience has shown, however, that Richardson's formula contained too little tannin; the quantity has been increased in the *U. S.* process to 20 per cent., but this is more than will usually

dissolve. The manipulation in the official formula might be improved by directing the tannic acid to be rubbed into a smooth paste in a mortar with sufficient alcohol, before introducing into the bottle. This would enable the pharmacist to prepare it extemporaneously. When applied on wounded or abraded surfaces, it soon loses the ether and alcohol, and a firm coating is left, in which, besides the tannin and colloidal substance, are the coagulated blood and secretions from the surface, forming a covering for the part by which the air is excluded. The liquid is applied with a camel's-hair brush, or by means of cotton saturated with it, to the edges of wounds closed by stitches, to ulcerated surfaces and bleeding parts. If it be desired to make a special impression on the diseased surface, phenol, creosote, iodine, morphine, etc., may be incorporated with the styptic fluid.¹

COLOCYNTHIS. *U. S. (Br.)*

COLOCYNTH [Bitter Apple]

(cōl-ō-cŭn'thīs)

"The peeled dried fruit of *Citrullus Colocynthis* Schrader (Fam. *Cucurbitaceæ*)." *U. S.*
 "The dried pulp of the fruit of *Citrullus Colocynthis*, *Schrad.*, freed from seeds." *Br.*

Colocynthis Pulpa, Br., Colocynth Pulp, Bitter Gourd, Apple, or Cucumber, Poma Colocynthis; Colocynthe, *Fr. Cod.*; Pulpe de Colocynthe, *Fr.*; Fructus Colocynthis, *P. G.*; Colocynthenapfel, Koloquintenmark, Koloquinten, *G.*; Colocynthide, *It.*; Colocynthida, *Sp.*

Citrullus Colocynthis (L.), Schrader, Engler and Prantl. *Cucumis Colocynthis*, Willd., *Sp. Plant.* iv. 611; Woodv., *Med. Bot.*, 189, t. 71. The bitter cucumber is an annual plant, bearing considerable resemblance to the common water-melon. The stems, which are herbaceous and beset with rough hairs, trail upon the ground, or rise upon neighboring bodies, to which they attach themselves by their numerous tendrils. The leaves, which stand alternately on long petioles, are triangular, many-cleft, variously sinuated; obtuse, hairy, of a fine green color on the upper surface, rough and pale on the under. The flowers are yellow, and appear singly at the axils of the leaves. The fruit is a globular pepo, of the size of a small orange, yellow and smooth when ripe, and contains, within a hard, coriaceous rind, a white, spongy pulp, enclosing numerous ovate, compressed, white or brownish seeds.

The plant is a native of Turkey, and abounds in the islands of the Archipelago. It grows also in various parts of Africa and Asia. Burekhardt, in his travels across Nubia, found the country covered with it; Thunberg met

¹ **Carbolized Styptic Colloid.**—In this preparation advantage is taken of the antiseptic and styptic properties of phenol, and a very effective hæmostatic results. It is made by adding ten per cent. of phenol to official styptic collodion.

with it at the Cape of Good Hope, and Ainslie says that it grows in many parts of Lower India, particularly in sandy places near the sea. It is said to be cultivated in Spain, the island of Cyprus, Morocco and in the neighboring countries, and even to have been collected in Japan. Colocynth from the maritime plain between the mountains of Palestine and the Mediterranean is chiefly shipped from Jaffa, and is known as *Turkish colocynth*. It is said to be of superior quality. The fruit is gathered in autumn, when it begins to become yellow, and, having been peeled, is dried quickly in a stove or in the sunshine. Thus prepared, it is imported from the Levant. Small quantities are said to be imported into England from Mogador in the form of brown, unpeeled globular gourds. The so-called *Persian colocynth* of the London markets is very small, and has apparently been compressed in a fresh state, so that the position of the seeds is perceptible through the dry pulp. The microscopic structure and the proportion of the pulp to the seed appear to be the same as in other colocynths. (*P. J.*, xvi. 107.) Colocynth has been grown in New Mexico, but, according to Sayre, the American colocynth possesses only about two-thirds the cathartic action of the Trieste variety.

Properties.—As found in commerce, colocynth is in the shape of whitish balls about the size of an orange, very light and spongy, and abounding in seeds which constitute three-fourths of their weight. The seeds are somewhat bitter, but possess little activity, and, according to Captain Lyon, are even used as food in the north of Africa.¹ When the medicine is prepared for use, they are separated and rejected, the pulpy or medullary matter only being employed. This has a very feeble odor, and a nauseous and intensely bitter taste. The U. S. Pharmacopeia thus describes colocynth: "Globular, from 5 to 10 Cm. in diameter, white or yellowish-white, light, spongy, separable longitudinally into three carpels, each containing near the outer surface numerous ovoid, compressed, whitish or light brown seeds; odor slight; taste intensely bitter. The seeds should be separated and rejected." U. S. "It should not yield the characteristic reactions with the tests for starch, and only traces of fixed oil should be removed from it by ether. It yields, when dried at 212° F. (100° C.) and incinerated, at least 9 per cent. of ash (indicating absence of seeds)." Br. Barclay considers the estimation of ash in powdered colocynth useful in proving its freedom from seeds.

The pulp yields from 8.6 to 14 per cent. of ash, the seeds from 2 to 4 per cent., the whole apple 4.6 per cent. (*Am. Drug.*, 1896, 152.) Water and alcohol extract the virtues of colocynth. It is a matter of importance to be able to determine whether the drug miller who usually powders colocynth is careful to reject the seeds. If the seeds have been ground with the dried pulp, the microscope will show the presence of numerous albuminous granules derived from the cotyledons. (W. T. Clark, *P. J.*, vii. 509.) These are best found by putting a small amount of the powder on the glass slide, adding a drop of water, and gently rubbing the cover glass over it; fragments of the double-walled embryo sac show on the outer side elongated, more or less hexagonal, thin-walled cells, and on the inner side irregular, tabular, thick-walled cells. If powdered colocynth contains a large number of starch granules it has probably been adulterated. Vauquelin obtained the bitter principle of colocynth in a separate state, and called it *colocynthin*. According to Meissner, 100 parts of the dry pulp of colocynth contain 14.4 parts of colocynthin, 10.0 of extractive, 4.2 of fixed oil, 13.2 of a resinous substance insoluble in ether, 9.5 of gum, 3.0 of pectic acid (pectin), 17.6 of gummy extract derived from the lignin by means of potassium hydroxide, 2.7 of calcium phosphate, 3.0 of magnesium phosphate, and 19.0 of lignin, besides water.² Colocynthin is obtained by boiling the pulp in water, evaporating the decoction, treating the extract thus procured with alcohol, evaporating the alcoholic solution, and submitting the residue, which consists of the bitter principle and potassium acetate, to the action of a little cold water, which dissolves the latter and leaves the greater part of the former untouched. Bastick obtained it by exhausting the pulp with cold water, heating the solution to ebullition, adding lead subacetate so long as a precipitate was produced, filtering the liquor when cold, adding diluted sulphuric acid gradually until it no longer occasioned a precipitate, boiling to expel free acetic acid, filtering to separate lead sulphate, evaporating cautiously nearly to dryness, extracting the colocynthin from the residue by strong alcohol, which left the salts, and finally evaporating the alcoholic solution.

The following process, employed by Walz, yields it in a purer state. Colocynth is exhausted by alcohol of sp. gr. 0.84, the tincture evaporated to dryness, the residue treated with water, and the solution precipitated first with lead acetate and afterwards with lead subacetate. The yellow filtered liquor is then treated with hydrogen sulphide to separate the lead,

¹ Nachtigal confirms this statement of Captain Lyon's, but with the qualification that, before being eaten, the seeds are deprived of their coating by some mechanical means, and the kernels are heated to the boiling point, then washed with cold water, dried, and powdered. Flückiger found a bitter principle in the testa, which accounts for its rejection as food, though rendering improper the rejection of the seed in preparing the extract. He found in the kernels about 45 per cent. of fixed oil and 18 per cent. of albumen. (*A. J. P.*, 1872, 538.)

² Walz supposed that he had found another peculiar principle, *colocynthinin*. It was obtained by treating with ether the alcoholic extract previously exhausted by water, decolorizing the ethereal solution with animal charcoal, evaporating to dryness, and dissolving the residue in anhydrous alcohol, which deposited it in crystals on spontaneous evaporation. It is white and tasteless, and is probably a resin. (*N. Jahrbuch der Pharm.*, xvi. 10.)

and, after filtration, with solution of tannic acid, which throws down a compound of tannic acid and colocynthin. This is dissolved in alcohol, the tannin thrown down by lead subacetate, the excess of lead separated, and the liquid digested with animal charcoal, filtered, and evaporated. The residue, washed with anhydrous ether, is pure colocynthin. This is yellowish, somewhat translucent, brittle and friable, fusible by a heat below 100° C. (212° F.), inflammable, more soluble in alcohol than in water, but capable of rendering the latter intensely bitter. Mouchon states that it is insoluble in ether. It is neither acid nor alkaline; but its aqueous solution gives with infusion of galls a copious white precipitate. Its formula, according to Walz, is $C_{58}H_{42}O_{23}$. Upon the same authority it is a glucoside, being resolved by the action of sulphuric acid into sugar and a peculiar resinous substance termed *colocyntheïn*, to which he gives the formula $C_{44}H_{32}O_{13}$. Henke doubts the probability of colocynthin being a glucoside, and states that it is uncrystallizable; he reviews the methods of previous investigators, and obtained by his own process but 0.66 per cent. of colocynthin. (*A. Pharm.*, 1883, p. 200; *A. J. P.*, 1883, p. 301.) According to Johannson, colocynthin, when heated with diluted sulphuric acid, yields colocyntheïn, elaterin, and bryonin. (*A. J. P.*, 1885, p. 451.)¹ An infusion of colocynth, made with boiling water, gelatinizes upon cooling. Neumann obtained from 768 parts of the pulp, treated first with alcohol and then with water, 168 parts of alcoholic and 216 of aqueous extract. (See also paper by George Wagner, *Proc. A. Ph. A.*, 1893, 179.)

Uses.—The pulp of colocynth is a powerful drastic, hydragogue cathartic, producing, when given in large doses, violent griping, and sometimes bloody discharges, with dangerous inflammation of the bowels. Death has resulted from a teaspoonful and a half of the powder. (Christison.) Even in moderate doses it sometimes acts with much harshness, and it is therefore seldom prescribed alone. By some writers it is said to be diuretic. It was frequently employed by the ancient Greeks and the Arabians, though its drastic nature was not unknown to them. Among the moderns it is occasionally used in obstinate dropsy, and in various affections depending on disordered action of the brain. In combination with other cathartics it loses much of its violence, but retains its purgative energy, and in this form is extensively employed. The compound extract of

colocynth is a favorite preparation with many practitioners, and, combined with calomel, extract of jalap, and gamboge, it forms a highly efficient and safe cathartic, especially useful in congestion of the portal circle and torpidity of the liver. (See *Pilulæ Catharticæ Compositæ*.) It is best administered in minute division, effected by trituration with gum or farinaceous matter. The active principle has sometimes been employed, and, in the impure state in which it is prepared by the process of Emile Mouchon, may be given in the dose of a grain (0.065 Gm.).

Thunberg states that the fruit of *C. Colocynthis*, at the Cape of Good Hope, is rendered so mild by being properly pickled that it is eaten both by the natives and by the colonists; but, as it is thus employed before attaining perfect maturity, it is possible that the drastic principle may not have been developed.

Dose, one to five grains (0.065 to 0.32 Gm.).

Off. Prep.—*Extractum Colocynthis, U. S.*; *Extractum Colocynthis Compositum, U. S.* (from extract), *Br.*; *Pilula Colocynthis Composita, Br.*; *Pilula Colocynthis et Hyoseyami, Br.* (from compound pill).

CONFECTIO PIPERIS. Br.

CONFECTION OF PEPPER

(cōn-fēc'ti-ō pīp'ē-rīs)

Electuarium Piperis; Electuaire de Poivre, Fr.; *Pfefferlatwerge, G.*

"Black Pepper, in fine powder, 2 ounces (Imperial) or 40 grammes; Caraway Fruit, in fine powder, 3 ounces (Imp.) or 60 grammes; Clarified Honey, 15 ounces (Imp.) or 300 grammes. *Mix.*" *Br.* This preparation was intended as a substitute for *Ward's Paste*, which acquired some reputation in Great Britain as a remedy in piles and ulcers of the rectum. To be of service, it must be continued, according to Brodie, for two, three, or four months. Its stimulating properties render it inapplicable to cases attended with much inflammation.

Dose, from one to two drachms (3.9 to 7.7 Gm.), repeated two or three times a day.

CONFECTIO ROSÆ. U. S. (Br.)

CONFECTION OF ROSE

(cōn-fēc'ti-ō rō'sæ)

Confectio Rosæ Gallicæ, Br.; *Confection of Roses; Conserva Rosarum; Conserve de Rose, Fr. Cod.*; *Conserve de Rose rouge, Fr.*; *Rosen-Conserve, G.*

* "Red Rose, in No. 60 powder, eighty grammes [or 2 ounces av., 360 grains]; Sugar, in fine powder, six hundred and forty grammes [or 22 ounces av., 252 grains]; Clarified Honey, one hundred and twenty grammes [or 4 ounces av., 102 grains]; Stronger Rose Water, one hundred and sixty cubic centimeters [or 5 fluidounces, 197 minims], to make about one thousand grammes [or 35 ounces av., 120

¹ According to Ernst Johannson (*In. Dis.*, Dorpat, 1884) colocynthin can readily be found in the saline discharges and in the body, after poisoning by it, by the following test: $\frac{1}{16}$ milligramme will give with concentrated sulphuric acid a reddish-yellow color, deepening into red; Froehde's reagent strikes with $\frac{1}{16}$ milligramme a cherry-red color; one part of ammonium vanadate in 200 parts of concentrated sulphuric acid makes with $\frac{1}{16}$ milligramme a blood-red spot surrounded by a bluish tint; alcohol with sulphuric acid strikes a yellow color, not altered by warming; selenosulphuric acid (H_2Se_3SO) does the same; basic lead acetate and tannic acid precipitate by weak solutions.

grains]. Rub the Red Rose with the Stronger Rose Water previously heated to 65° C. (149° F.), then gradually add the Sugar and Clarified Honey, and beat the whole together until a uniform mass results." *U. S.*

"Fresh Red-Rose Petals, *one pound* (Imperial) or 500 grammes; Refined Sugar, *three pounds* (Imp.) or 1500 grammes. Beat together in a stone mortar." *Br.*

This preparation does not differ from that formerly official.

In the British process the unblown petals only are used, and these should be deprived of their claws; in other words, the rose-buds should be cut off a short distance above their base, and the lower portion rejected. In the last four editions of the U. S. Pharmacopœia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex. We have been informed, however, that confection of rose is still made in Philadelphia on a large scale from the fresh petals of the hundred-leaved rose and others, by beating them into a pulp with sugar, as in the British process. An excuse for this deviation from the official formula is, that the confection thus made has greater adhesiveness than the official, and is therefore better fitted for the formation of pills. Confection of Rose is slightly astringent, but is used almost exclusively as a vehicle, or to impart consistence to the pilular mass.

CONFECTIO SENNÆ. U. S., Br.

CONFECTION OF SENNA

(cōn-fēc'ti-ō sēn'na)

Electuarium Sennæ Compositum, Electuarium Lentivum; Electuaire de Séné composé, *Fr. Cod.*; Electuaire lentif, *Fr.*; Electuarium e Senna, *P. G.*; Sennalutwerge, *G.*; Electuario lentivo, *It.*

* "Senna, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Cassia Fistula, bruised, *one hundred and sixty grammes* [or 5 ounces av., 282 grains]; Tamarind, *one hundred grammes* [or 3 ounces av., 231 grains]; Prune, sliced, *seventy grammes* [or 2 ounces av., 205 grains]; Fig, bruised, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Sugar, in fine powder, *five hundred and fifty-five grammes* [or 19 ounces av., 252 grains]; Oil of Coriander, *five grammes* [or 77 grains]; Water, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Digest the Cassia Fistula, Tamarind, Prune and Fig with *five hundred cubic centimeters* [or 17 fluidounces] of Water in a covered vessel, by means of a water-bath, for three hours. Separate the coarser portions and rub the pulpy mass, first through a coarse hair sieve, and then through a muslin cloth. Mix the residue with *one hundred and fifty cubic centimeters* [or 5 fluidounces] of Water, and, having digested the mixture for a short time, treat it as before, and add the product to the pulpy mass first obtained. Then, by means of a

water-bath, dissolve the Sugar in the pulpy liquid, and evaporate the whole in a tared vessel, until it weighs *eight hundred and ninety-five grammes* [or 31 ounces av., 250 grains]. Lastly, add the Senna and the Oil of Coriander, and incorporate them thoroughly with the other ingredients while they are yet warm." *U. S.*

"Senna, in fine powder, *7 ounces* (Imperial) or 140 grammes; Coriander Fruit, in fine powder, *3 ounces* (Imp.) or 60 grammes; Figs, *12 ounces* (Imp.) or 240 grammes; Tamarinds, *9 ounces* (Imp.) or 180 grammes; Cassia Pulp, *9 ounces* (Imp.) or 180 grammes; Prunes, *6 ounces* (Imp.) or 120 grammes; Extract of Liquorice, *1 ounce* (Imp.) or 20 grammes; Refined Sugar, *30 ounces* (Imp.) or 600 grammes; Distilled Water, *a sufficient quantity*. Boil the Figs and Prunes gently with *twenty-four ounces* (Imp.) or four hundred and eighty grammes of Distilled Water in a covered vessel for four hours; add more Distilled Water to make up the quantity to its original volume, and then incorporate the Tamarinds and Cassia Pulp; digest for two hours; rub the softened pulp of the fruits through a hair sieve, rejecting the seeds and other hard parts; to the pulp thus obtained add the Refined Sugar and Extract of Liquorice, dissolving them by the aid of gentle heat; while the mixture is still warm, add to it gradually the mixed Senna and Coriander powders; mix the whole thoroughly; make the weight of the resulting Confection *seventy-five ounces* (Imp.) or fifteen hundred grammes, either by evaporation or by the addition of more Distilled Water." *Br.*

Confection of Senna, when correctly made, is an elegant preparation, and keeps well if properly protected. The present U. S. process differs from that of 1860 in preparing the pulps, as suggested in former editions of this Dispensatory, instead of taking them already prepared. The present preparation contains about 10 per cent. more sugar than that official in 1880. An improvement was made in the process of the U. S. P. 1890 by replacing the coriander seed of the former Pharmacopœias with oil of coriander; it is almost impossible to powder coriander fine enough to avoid hard particles except by drying it to such an extent as to deprive it injuriously of its volatile oil, and the plan of using the oil directly has therefore been adopted. The oil of coriander should be dropped upon a portion of the powdered senna contained in a mortar or suitable vessel and this lightly triturated with the rest of the powdered senna so as to distribute it uniformly; the mixture should then be added to the pulpy mass and the official directions then carried out. It was formerly not uncommon to omit the cassia pulp in this preparation, as the pods were not always to be found in the market; but, as this is next to senna the most active ingredient, the omission was to be regretted. Cassia fistula is now readily procured in commerce, and there can be no excuse for its omission. It has also been proposed to substitute

the fluidextract of senna for the crude drug (*A. J. P.*, xliii. 123); but, as the fluidextract is of such uncertain quality, the leaves themselves are preferable.

A very good, pleasant laxative, admirably adapted to cases of habitual costiveness, especially in pregnant women, and in persons affected with piles.

Dose, one to two drachms (3.9 to 7.7 Gm.), at bedtime.

CONFECTIO SULPHURIS. Br.

CONFECTION OF SULPHUR

(cōn-fēc-tī-ō sūl'phū-rīs)

Electuarium Sulphuris; Electuaire de Soufre, *Fr.*; Schwefellatwerge, *G.*

"Sublimed Sulphur, 4 ounces (Imperial) or 100 grammes; Acid Potassium Tartrate, in powder, 1 ounce (Imp.) or 25 grammes; Tragacanth, in powder, 18 grains (Imp.) or 1 gramme; Syrup, 2 fl. ounces (Imp. meas.) or 50 cubic centimetres; Tincture of Orange, $\frac{1}{2}$ fl. ounce (Imp. meas.) or 12.5 cubic centimetres; Glycerin, $1\frac{1}{2}$ fl. ounces (Imp. meas.) or 37.5 cubic centimetres. Mix." *Br.*

This is merely a mode of administering the two laxatives, sulphur and potassium bitartrate, and the relative proportion of the latter is so small that it can have little effect. The addition of tragacanth is due to a suggestion of Peter Boa, who found that without it a syrupy layer of liquid formed on top of the confection. (*P. J.*, 1882, 682.) The syrup of orange peel, formerly directed, has been replaced in the *Br. Pharm.* (1898) by syrup and tincture of orange, evidently because the syrup of orange peel did not keep well, while the glycerin serves to retain the proper consistence of the confection.

Dose, one to two drachms (3.9 to 7.7 Gm.) or more.

CONFECTIONES.

CONFECTIONS

(cōn-fēc-tī-ō'nēs)

Electuaries; Conserves, Électuaires, Saccharolés mous, *Fr.*; Conserven, Latwergen, *G.*; Elettuaro, *It.*; Electuario, *Sp.*

Under the general title of Confections, the Pharmacopœias include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. But two confections have been retained in the Eighth Revision of the U. S. Pharmacopœia. The old division into Conserves and Electuaries has been abandoned; but, as there is some ground for the distinction, we shall make a few general remarks upon each division before proceeding to the consideration of the individual preparations.

Conserves consist of undried vegetable substances and refined sugar beaten into a uniform

mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now used are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be in fine powder.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for official direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary be found, after having been kept for a short time, to swell up and emit gas, it should be beaten over again in a mortar, so that any portion of the sugar which may have crystallized may be again accurately incorporated with the other ingredients. Should it, on the contrary, become dry and hard from the mutual reaction of its constituents, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup, and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose, but its taste might be objectionable. Some employ honey, but this is not always acceptable to the stomach. Glycerin and syrupy glucose might sometimes be used with advantage.¹

¹ *Confectio Aromatica, Aromatic Confection, Electuarium Aromaticum; Electuaire (Confection) aromatique, Fr.*; Aromatische Latwerge, Getwürzlatwerge, *G.*—"Take of Aromatic Powder four troy-ounces; Clarified Honey four troy-ounces, or a sufficient quantity. Rub the Aromatic Powder with Clarified Honey until a uniform mass of the proper consistence is obtained." *U. S.* 1870. This confection affords a convenient means of administering the spices contained in it, and an agreeable vehicle for

CONII FOLIA. Br.

HEMLOCK LEAVES

(cō-nī fō'li-ā)

"The fresh leaves and young branches of *Conium maculatum*, Linn., collected when the fruit begins to form." Br.

CONIUM [Poison Hemlock]

(cō-nī'ūm)

"The full-grown, but unripe fruit of *Conium maculatum* Linné (Fam. *Umbelliferae*), carefully dried and preserved, and yielding, when assayed by the process given below, not less than 0.5 percent. of coniine. After being kept for more than two years, Conium is unfit for use." U. S. "The dried, full-grown, unripe fruits of *Conium maculatum*, Linn." Br.

Conii Fructus, Br., Hemlock Fruit, Conium Seed; Cigué ordinaire, Grande Cigué (Fruit), Fr. Cod.; Gefleckter Schierling, Schierlingsfrüchte, G.; Frutti di cicuta maggiore, It.; Fruto di cicuta, Sp.

Conium maculatum, Willd., *Sp. Plant.* i. 1395; Bigelow, *Am. Med. Bot.*, i. 113; Woodv., *Med. Bot.*, p. 104, t. 42.—This is an umbelliferous plant, having a biennial spindle-shaped whitish root, and an herbaceous branching stem, from three to six feet high, round, hollow, smooth, shining, slightly striated, and marked with brownish-purple spots. The lower leaves are tripinnate, more than a foot in length, shining, and attached to the joints of the stem by sheathing petioles; the upper are smaller, bipinnate, and inserted at the division of the branches; both have channelled footstalks, and incised leaflets, which are deep green on their upper

surface and paler beneath. The flowers are very small, white, and disposed in compound terminal umbels. The general involucre consists of from three to seven lanceolate, reflected leaflets, whitish at their edges; the partial involucre of three or four leaflets, oval, pointed, spreading, and on one side only. There are five petals, cordate, with their points inflexed, and nearly equal. The stamens are spreading, and about as long as the corolla; the styles diverging. The fruit, commonly called seed, is roundish-ovate, a line and a half or rather less in length by a line in breadth, striated, and composed of two plano-convex, easily separable parts, which have on their outer surface five crenated ribs separated by slightly wrinkled furrows. On cross section the absence of oil ducts becomes apparent, and a deep furrow upon the commissural face of the albumen gives a reniform appearance. As kept in the shops, the mericarps are usually separated. They are thus officially described: "Broadly ovoid, greenish-gray, the two carpels of most of the fruits separated, each about 3 Mm. long and about 1.5 Mm. in diameter, ovoid, somewhat curved, the inner, flattened side marked by a deep longitudinal groove, the outer, convex side with five pale yellow, somewhat crenate ribs, the intervening surfaces wrinkled but otherwise smooth; pericarp without oil-tubes; odor slight, but when triturated with a solution of potassium hydroxide, strong, disagreeable, and mouse-like; taste characteristic, disagreeable, afterwards somewhat acrid." U. S.

Conium is a native of Europe, and has become naturalized in the United States, where it is also cultivated for medicinal purposes. It grows usually in clusters along the roadsides or in waste grounds, and is found most abundantly near old settlements. It flowers in June and July. The whole plant, especially at this period, exhales a fetid odor, compared by some to that of mice, by others to that of the urine of cats, and narcotic effects result from breathing for a long time air loaded with the effluvia. The plant varies in narcotic power according to the weather and climate, being most active in hot and dry seasons and in warm countries. The hemlock of Greece, Italy, and Spain is said to be much more energetic than that of the north of Europe. As a rule, those plants are most active which grow in a sunny exposure. The term *cicuta*, which has often been applied to this plant, belongs to a different genus. The leaves and fruit are official in the British Pharmacopœia while the fruit alone is official in the U. S. Pharmacopœia. The proper season for gathering the leaves is when the plant is in flower, and Fothergill asserts, from experiment, that they are most active about the time that the flowers begin to fade. The footstalks¹ should be rejected, and the leaflets quickly dried, either in the hot sun, or on

other medicines. The confection is given in debilitated states of the stomach. The dose is from ten to sixty grains (0.65 to 3.9 Gm.).

Confectio Aurantii Corticis, *Confection of Orange Peel*, Conserva Aurantii; Conserve d'Ecorce d'Orange, Fr.; Apfelsinenschalen-Conserve, G.—"Take of Sweet Orange Peel, recently separated from the fruit by grating, twelve troyounces; Sugar [refined] thirty-six troyounces. Beat the Orange Peel with the Sugar, gradually added, until they are thoroughly mixed." U. S. 1870. This confection is not used as frequently as it deserves to be. It is, when well made, a grateful aromatic vehicle or adjuvant for tonic and purgative powders.

Confectio Opii, *Confection of Opium*, which was the modern substitute for the medieval preparations known as *theriaca* and *mithridate*, has been finally dropped from both Pharmacopœias. One grain of opium was contained in about thirty-six grains of the former United States confection, and in about forty grains of the British. The following is the U. S. Pharmacopœia (1870) formula: "Take of Opium, in fine powder, two hundred and seventy grains; Aromatic Powder six troyounces; Clarified Honey fourteen troyounces. Rub the Opium with the Aromatic Powder, then add the Honey, and beat the whole together until thoroughly mixed." U. S. 1870.

¹ Manlius Smith of Manlius, N. Y., has demonstrated that the footstalks are almost destitute of the active alkaline principle. (*Ann. Ther.*, 1873, p. 39.)

tin plates before a fire, or by a stove-heat not exceeding 120° F. They should be kept in boxes or tin cases, excluded from the air and light, by exposure to which they lose their fine green color and become deteriorated. The same end is answered by pulverizing them, and preserving the powder in opaque and well stoppered bottles. But little reliance can be placed on the dried leaves, as, even when possessed of a strong odor and a fine green color, they may be destitute of the narcotic principle. When rubbed with potassium hydroxide they should exhale the odor of coniine. The fruit retains its activity much longer than the leaves. Christison found them to have sustained no diminution of power after having been kept eight years. Hirtz inferred from experiment that extract of the seeds was ten times stronger than that of the leaves. Commercial conium occasionally contains other umbelliferous plants, or it may be almost wholly composed of such plants, and even anise has been used as an adulterant to the fruit. The presence of such impurities is to be recognized by physical examination.

Properties.—The dried leaves of the hemlock have a strong, heavy, narcotic odor, less disagreeable than that of the recent plant. Their taste is bitterish and nauseous; their color a dark green, which is retained in the powder. A slight degree of acrimony possessed by the fresh leaves is said to be dissipated by drying. The seeds have a yellowish-gray color, a feeble odor, and a bitterish taste. Their form has already been described. Water distilled from the fresh leaves has the odor of hemlock, and a nauseous taste, but does not produce narcotic effects. The decoction has little taste, and the extract resulting from its evaporation is nearly inert. From these facts it is inferable that the active principle, as it exists in the plant, is not volatile at 100° C. (212° F.) and, if soluble in water, is injured by a boiling heat. Alcohol and ether take up the narcotic properties of the leaves, and the ethereal extract, which is of a rich dark green color, is stated by A. T. Thompson to have the odor and taste of the plant in perfection, and in the dose of half a grain to produce headache and vertigo. Upon destructive distillation, the leaves yield a very poisonous empyreumatic oil. Geiger was the first who obtained the active principle in a separate state, and proved it to be alkaline. It appears that there are two volatile substances in hemlock; one of them an oil, which is in very small quantity, and is obtained by simple distillation; the other, the volatile alkaloid coniine, or *conine*, which is the active principle. As it exists in the plant in combination with an acid, it is not readily volatilized, but it freely comes over with the distillate when an alkali has been previously added. The acid of conium Peschier believed to be peculiar, and named *coniic acid*. Other observers assert that it is *malic acid*. Geiger obtained coniine by the following process. He distilled fresh hem-

lock with potassium hydroxide and water, neutralized with sulphuric acid the alkaline liquid which came over, evaporated this liquid to the consistence of syrup, added anhydrous alcohol so long as a precipitate of ammonium sulphate was afforded, separated this salt by filtration, distilled off the alcohol, mixed the residue with a strong solution of potassium hydroxide, and distilled anew. The coniine passed over with the water, from which it separated, floating on the surface in the form of a yellowish oil. According to Christison, an easier process is to distil cautiously a mixture of a strong solution of potassium hydroxide and the alcoholic extract of the unripe fruit. J. Schorm suggests an improvement in the process, which yields a purer coniine, in *Ber. d. Chem. Ges.*, 1881, 1765; also *N. R.*, Dec. 1881. As obtained by the above process, coniine is in the state of an hydroxide, containing one-fourth of its weight of water and a little ammonia. From the former it may be freed by calcium chloride; from the latter, by exposing it under an exhausted receiver until it ceases to emit bubbles of gas.

The fresh leaves or seeds should be employed in the preparation of coniine, as the alkaloid undergoes decomposition by time and exposure. The seeds contain most of this principle; but even in these it exists in very small proportion. From 6 pounds of the fresh and 9 of the dried seeds, Geiger obtained about an ounce of coniine, while from 100 pounds of the fresh herb only a drachm, and from the dried leaves none. Christison recommends the full grown fruit while yet green, and states that 8 pounds will yield half an ounce of coniine hydroxide, and contain much more. In relation to the relative strength of different parts of the plant, Manlius Smith of New York, gives as the result of a series of carefully conducted experiments that the unripe fruit of the conium is far preferable to the dried leaves, and is even stronger than the full grown fruit, that it may be dried without serious injury, and that a very active preparation may be made from it. He also found that full grown fruit collected in August, and dried in the dark, retained its activity unimpaired for several years. This would appear to contradict in some measure previous opinions of the injurious effects of time. (*P. J.*, Feb. 1869, 491-2.) Farr and Wright (*P. J.*, 1896, 273) confirm the views of Harley and Manlius Smith, and affirm that green fruits are alone reliable. The volatility and tendency to undergo decomposition of coniine probably has its effect even in the dried unripe seed, otherwise it is difficult to explain the fact that in thirteen analyses of commercial conium fruit made by Farr and Wright, the average alkaloidal contents were 0.674; while the average of sixteen analyses of samples collected by themselves was 2.13. (*P. J.*, Feb., 1904.) For a method of assaying conium fruit, by Schwickerath, see *Ph. Rec.*, 1893, 282. The U. S. P. (8th Rev.) adopted the following

assay process, requiring that conium should yield not less than 0.5 per cent. of coniine.

Assay. U. S. (8th Rev.).—"Conium, in No. 60 powder, *ten grammes*, Ether, Alcohol, Ammonia Water, Normal Sulphuric Acid V.S., Sodium Carbonate T.S., Distilled Water, Hydrochloric Acid Solution (5 percent. HCl), each, a *sufficient quantity*. Place the Conium in a 200 Cc. Erlenmeyer flask, add 100 Cc. of a mixture of ether 98 parts, alcohol 8 parts, and ammonia water 3 parts (by volume), insert the stopper securely, and shake the flask at intervals during four hours. After the powder has settled, decant 50 Cc. of the clear liquid into a beaker (representing 5 Gm. of Conium), and add sufficient normal sulphuric acid V.S. to produce a distinctly acid reaction. Evaporate the ether at a gentle heat by the aid of a water-bath; then add 15 Cc. of alcohol, and set the beaker aside in a cool place for two hours to allow the ammonium sulphate to deposit. Filter the liquid; wash the residue and filter with a little alcohol, and add the washings to the filtrate; neutralize any excessive amount of acid with sodium carbonate T.S., being careful to retain a slight acidity. Concentrate the liquid to 3 Cc. by the aid of a gentle heat on a water-bath, add 3 Cc. of distilled water and 2 drops of normal sulphuric acid V.S. Add 15 Cc. of ether to remove traces of fatty matter, pour off the ether-solution and repeat the washing with 15 Cc. of ether. Then transfer the acid liquid to a separator, introduce a small piece of red litmus paper, and add sufficient sodium carbonate T.S. to render the liquid slightly alkaline; then shake out with successive portions of 15, 15, and 10 Cc. of ether. To the combined ether-solutions in a tared beaker, add, drop by drop, sufficient hydrochloric acid solution (5 percent.) to insure an excess of acid, and then evaporate the ether by a gentle heat on a water-bath. Remove the excess of hydrochloric acid by adding to the residue 3 Cc. of alcohol and heating gently to evaporate the liquid, repeat this operation once, and dry the residue at a temperature not exceeding 60° C. (140° F.) until the weight, after cooling in a desiccator, remains constant. The weight of the residue multiplied by 0.777, and this product by 20, gives the percentage of coniine contained in the Conium." U. S.

Coniine, $C_8H_{17}N$, has been thoroughly studied by Hofmann (1881), who established the correct formula as given, instead of $C_8H_{15}N$, as it was formerly assumed, and Ladenburg (1886), effected its synthesis from *allyl pyridine* by reduction with sodium in alcoholic solution:

This reaction gives *a-normal propyl piperidine*, which is optically inactive, but by the crystallization of its tartrate splits into *coniine* (dextro-rotatory) and a very similar *laevo-rotatory coniine*, just as racemic acid splits into dextro-rotatory and laevo-rotatory tartaric acid.

Coniine is in the form of a yellowish oily liquid, of sp. gr. 0.862, of a very acrid taste, and a strong penetrating odor, compared to that of the urine of mice, and recalling the odor of fresh hemlock, though not identical with it. In volatility it resembles the essential oils, readily rising with the vapor of boiling water, but when unmixed requiring for ebullition a temperature of 166° C. (330.8° F.). It is freely soluble in alcohol, ether, and the fixed and volatile oils, and slightly so in water. It unites with about one-fourth of its weight of water to form a hydroxide. It reddens turmeric, and neutralizes the acids, forming with them soluble salts, some of which are crystallizable. With tannic acid it forms an insoluble compound. Like ammonia, it occasions a white cloud when approached by a rod moistened with hydrochloric acid; and the resulting hydrochloride is crystallizable, and not in the least deliquescent. The hydrochloride may also be obtained as a brilliant crystalline mass by dissolving coniine in anhydrous ether and passing dry hydrochloric acid gas through the solution. The salt is very soluble in water and alcohol, but insoluble in ether. It can be heated to 90° C. without decomposition, and melts at 218° C. Coniine coagulates albumin, and precipitates the salts of aluminum, copper, zinc, manganese, and iron. It also precipitates silver nitrate, but in excess redissolves the precipitate. Most of its salts are decomposed by evaporation. When exposed to the air, it speedily assumes a deep brown color, and is ultimately converted into a resinous matter, and into ammonia, which escapes. Under the influence of heat this change takes place with much greater rapidity. The presence of coniine may be detected in an extract or other preparation of hemlock by rubbing it with potassium hydroxide, which instantly develops its peculiar odor.¹ It is a most energetic poison.

In association with coniine in the hemlock are found also the following bases: *Ethyl-piperidine*, $C_7H_{15}N$ or $C_8H_{10}(C_2H_5)N$; *Methyl-coniine*, $C_9H_{19}N$ or $C_8H_9(C_3H_7)N(CH_3)$; *Conhydrine*, $C_8H_{17}NO$ or $C_8H_9(CHOH.CH_2CH_3)NH$; *Pseudo-conhydrine*, $C_8H_{17}NO$ or $C_8H_9(CH_3.CHOH.CH)NH$; *Methyl-coniine*, first obtained by Kekulé and von Planta in commercial coniine, is of minor importance.

Conhydrine is crystallizable, fusible below 100° C. (212° F.), and volatilizable at a higher temperature, diffusing the peculiar odor of

¹ Orfila gives the following additional chemical characters of coniine. Heated in a porcelain dish, it forms white vapors having a strong odor of celery and of the urine of mice. Weak tincture of iodine gives a white precipitate, becoming olive with excess of the tincture. Pure concentrated sulphuric acid does not alter it; but when the mixture is heated, it becomes first brown, then blood-red, and finally black. Nitric acid imparts a topaz color, not changed by heat. Platinum and gold chlorides give yellow precipitates, and corrosive sublimate a white one. Potassium permanganate is immediately decolorized. Neutral lead acetate gives no precipitate, nor does the subacetate. The parts of this note in italics indicate the means of distinguishing this alkaloid from nicotine. (See P. J., xi. 89.)

coniine, or one very much like it. Water dissolves it considerably, ether and alcohol freely; and the solution has a strong alkaline reaction. Its formula is given as $C_8H_{17}NO$. By the action of P_2O_5 or fuming hydrochloric acid upon conhydrine is obtained *coniceine*, $C_8H_{15}N$, and water. It may be separated from coniine by exposing the mixed alkaloids to a freezing mixture, expressing, and then repeatedly crystallizing from ether. (*Gmelin*, xiii. 169.) E. Merck obtained a small quantity of a new alkaloid from the high boiling portion of crude coniine. The isolation was accomplished by fractional distillation *in vacuo* and recrystallization. The alkaloid crystallizes in needles, is easily soluble in water, alcohol, ether, benzene, and chloroform, fuses at about $98^\circ C$, and boils at 230° to $232^\circ C$. According to Ladenburg, the alkaloid is an isomer of conhydrine, having the formula $C_8H_{17}NO$, and for this reason the name *pseudo-conhydrine* was selected. (*Chem. Cb.*, 1891, 414; see also *P. J.*, 1891, 1170.)

Paraconiine.—Coniine was supposed to have been artificially produced by Hugo Schiff. From the reaction of *butyric aldehyde* with an alcoholic solution of ammonia, he obtained two bases, one of which, *dibutyraldine*, yielded, on distillation, first a neutral oily substance, and afterwards a strong alkaline base, which proved to have the physiological properties of natural coniine, but was optically inactive, while true coniine is dextro-rotatory. Since the change in the formula of true coniine it will be seen that the base *paraconiine*, which is $C_8H_{15}N$, is not even isomeric with coniine.

Uses.—Hemlock is supposed to be the narcotic used by the Athenians to destroy the life of condemned individuals, and by which Socrates and Phocion died. It was also used by the ancients as a medicine, but fell into entire neglect until Störck employed and extravagantly praised it. Though fatal to some animals, hemlock is eaten with impunity by others, as horses, goats, and sheep. Anodyne, soporific, antispasmodic, antaphrodisiac, deobstruent, and diuretic properties have been ascribed to it, but it possesses none of them.

Modern research has, however, greatly limited the use of the medicine, rendering its possession of alternative properties extremely doubtful. When taken internally in sufficient dose it produces very profound muscular weakness, associated, it may be, with vertigo and disordered vision. After toxic doses the muscular prostration is extreme, the eyelids droop from weakness, the voice is suppressed, the pupils dilated, the sight almost lost; consciousness is usually preserved to the last, and life finally is extinguished without a struggle. In some cases there have been convulsive movements, and violent cardiac palpitation has been noted. The chief action of the poison is upon the motor nerves, which it paralyzes; the efferent or sensitive nerves are also affected, but to a much less extent. Conium probably

exerts no direct influence upon the cerebral centres, but there is some reason for believing that it is a spinal depressant. At present conium is rarely employed by the general practitioner, except in spasmodic affections, such as *chorea* and *whooping cough*. Probably the most frequent use of it is by alienists for the production of calm in cases of *maniacal excitement*.

The juice of the fresh leaves of conium is much used in England, but the fluidextract of the U. S. Pharmacopœia, made from the fruit, is the best of all preparations. The powdered leaves may be given in the dose of three or four grains (0.20 to 0.26 Gm.) twice a day gradually increased until the occurrence of slight vertigo or nausea indicates that it has taken effect. To maintain a given impression, it is necessary to increase the dose even more rapidly than is customary with most other narcotics, as the system becomes very speedily habituated to its influence. In some instances the quantity administered in one day has been augmented to more than two ounces. The strength of the preparations of hemlock is exceedingly unequal, and caution is therefore necessary, when the medicine is given in very large quantities, to employ the same parcel, or, if a change be made, to commence with the new parcel in small doses, so as to obviate any danger which might result from its greater power. Unpleasant consequences have followed a neglect of this precaution. There is also an official tincture, besides the fluidextract, both of which, when properly made, are considered efficient preparations, but the alcoholic extract formerly official was dropped at the 8th Revision because of its uncertain action. The expressed juice of the fresh plant, with a little alcohol for its preservation, is one of the most reliable forms in which the leaves can be used. The powdered seeds should be given in a dose considerably smaller than that of the leaves.¹ The fresh leaves are sometimes used externally as an anodyne cataplasm, and the extract, and an ointment prepared from the leaves, are applied to the same purpose. A plaster made from the extract has also been employed.²

Coniine acts precisely as does hemlock, and may be used for the same purposes. The dose is from one-sixth to one-fourth minim (0.01 to 0.015 Cc.). A solution of one part in one hundred of very dilute alcohol has been used with advantage in certain cases of *scrofulous ophthalmia* with photophobia, applied several times

¹ The root, while containing a small proportion of coniine, is too feeble, according to the experiments of John Harley of London, to be used practically with advantage. Harley has found in the root three new proximate principles, one a very bitter resin, which he names *conamarine*, and the two others crystallizable bodies, named respectively *rhizocoinin* and *rhizocolein*. They are all neutral, and, so far as known, medicinally inert. (See *P. J.*, Aug. 1867.)

² The following formula of Planché has been approved by the Society of Pharmacy of Paris. Take of extract of hemlock 90 parts, of purified elemi 20 parts, of white wax 10 parts. Melt the resin and wax with a gentle heat and incorporate the extract with the mixture. (*J. P. C.*, Juillet, 1862, p. 46.)

daily by friction about the eyelids. (*J. P. C.*, 3e sér., xix. 219.) Mauthner of Vienna, recommends it especially in the spasmodic contraction of the orbicularis oculi in scrofulous children, using a solution containing half a grain of conium in a drachm of almond oil, which he applies by a pencil to the eyelids twice or thrice daily. As a collyrium, from one to three drops may be added to six drachms of pure water, and two drachms of mucilage of quince seeds, the whole should then be carefully strained.

Conium hydrochloride has been recommended for exhibition by G. C. Close, as preferable to the uncombined alkaloid. From half a grain he experienced no sensible effects, but a grain produced the characteristic symptoms of coniine in an even unpleasant degree. These doses are probably dangerous, and not more than a sixth of a grain (0.01 Gm.) should be given as a commencing dose. (*A. J. P.*, 1869, p. 62.) Harley has prepared an acid *coniine benzoate* by adding two molecules of the acid to one of the base, and found the resulting salt effectual in the dose of half a grain. (*P. J.*, Jan. 1871, p. 585.) According to Mourrut, one of the best crystallizable salts of coniine is the *hydrobromide*. The alkaloid is treated with aqueous hydrobromic acid, which causes, especially with the brown variety of coniine, an elevation of temperature, and a disengagement of white fumes of the odor of coniine; the mixture then turns green, and finally blackish-red. The crystals, which form after some time, may be obtained quite colorless by repeated crystallizations. They are colorless prismatic needles, soluble in water and alcohol, less so in ether and chloroform, inodorous and almost tasteless, and are not deliquescent. They should be kept in the dark, otherwise they assume a red tint. The salt has been used by various practitioners with great success in the treatment of *whooping cough*, in doses of about one-twelfth of a grain (0.005 Gm.), if necessary, every hour, for a child three years of age; or one-thirtieth of a grain (0.002 Gm.) for a child of one year; or one-sixth of a grain (0.01 Gm.) for adults. In *sciatica* it has been employed hypodermically in quantities of one-twelfth of a grain (0.005 Gm.) with good results. (*Répert. de Pharm.*, 1876, p. 369; *N. R.*, 1876, 1879, pp. 18, 178.) For an account of Harley's experiments, to determine the relative value of different preparations of conium, see *U. S. D.*, 18th ed. p. 451. He concluded that the green fruit, as the basis of tinctures and extracts, is superior to any other part of the plant, and the spirituous extract of the green fruit should be substituted for the almost worthless extract of the *Br. Pharm.* (*P. J.*, 1871, p. 585.)

Dose, of conium, three to five grains (0.2 to 0.32 Gm.).

CONVALLARIA. U. S.

CONVALLARIA [Lily-of-the-Valley]

(cōn-vāl-lā'ri-q)

"The dried rhizome and roots of *Convallaria majalis* Linné (Fam. *Liliaceæ*)." *U. S.*

Lilium Convallium; Muguet, *Fr. Cod.*; Maiblumen, *G.*; Convallaria, *Mughetto, It.*; Convalaria, *Lirio de los valles, Sp.*

The ordinary lily of the valley of the gardens is a low, perennial herb, having slender running root-stocks, which send up each spring from the scaly sheathing bud two oblong, bright green, smooth leaves, whose long sheathing petioles are so enrolled as to appear like a stalk, and producing in late spring or early summer a one-sided raceme of beautiful, sweet-scented, nodding, bell-shaped flowers, placed upon an angular scape. It is primarily a native of Europe, but may be found in America escaped from gardens, and a plant which grows wild in the higher Alleghanies from Central Virginia to South Carolina seems to be identical with it. The root-stock of the lily of the valley occurs in pieces two to three inches long, covered with a mass of contorted, fine, almost fibrous rootlets. It is much thicker at one end, to which are attached the remains of the petioles and scape, and rapidly or sometimes almost abruptly tapers towards the slender end. The thick end is much gnarled and wrinkled, with leaf-scars. It is officially described as follows: "Rhizome of horizontal growth, somewhat branched, length variable, 1 to 3 Mm. thick, cylindrical, whitish or pale-brown, marked with few circular stem-scars and at each joint with a circle of root-scars or thin, tortuous and branched roots; fracture fibrous but weak; internally whitish; odor distinct; taste sweetish, bitter, and slightly acrid." *U. S.* G. F. Walz found in lily of the valley *convallarin* and *convallamarin*. (*A. J. P.*, 1859, p. 577.) *Convallarin* is in colorless rectangular prisms, scarcely soluble in water, but sufficiently so as to render the solution acid and to cause it when shaken to foam like soap and water. It is easily dissolved by alcohol. Its composition is represented by the formula $C_{34}H_{52}O_{11}$, and it is decomposed by long boiling with diluted acids into sugar and *convallaretin*. It is a glucoside. *Convallamarin* is a white powder, very bitter and afterwards sweetish, soluble in water and alcohol, but not in ether. This also is a glucoside. Its composition is $C_{23}H_{44}O_{12}$, and it is decomposed by heating with diluted sulphuric acid into sugar and *convallamaretin*, the formula of which is $C_{20}H_{36}O_8$. For preparing *convallamarin* Tanret modifies Walz's method, as follows. An alcoholic tincture made from the whole plant is precipitated with lead subacetate and filtered; the excess of lead is removed with diluted sulphuric acid, avoiding the use of more than is necessary, and, after neutralizing, the tincture is distilled, the last portion of alcohol being

driven off in the open air, then the cooled and filtered liquor is treated with tannin, care being taken to keep the liquid neutral by cautiously adding a diluted solution of sodium carbonate. A compound of tannin and convallamarin is precipitated, which, after washing, is dissolved in 60° alcohol, the solution decolorized with charcoal, decomposed with zinc oxide, filtered, and evaporated to dryness. In this way convallamarin is obtained nearly white, and having the appearance of ordinary digitalin. To free it from the salts that are sometimes carried down by the tannin precipitate, it is a good plan to redissolve it in 90° alcohol, filter, and then evaporate. One kilogramme of the fresh plant collected in the first days of August yielded two grammes of convallamarin. (P. J., 1882, p. 423.) Taken internally the flowers are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in *epilepsy* and against *worms*. The root, which is also bitter, has similar purgative properties, and in powder is said to be sternutatory. Hænsel obtained 0.058 per cent. of an aromatic volatile oil from the leaves of *Convallaria majalis* (Ph. Centralh., 1901, 495).

Uses.—The lily of the valley is stated to have been long used in Russia for the relief of *dropsy*, and in 1880 Troitzky and Bojowlewsky commended it highly to the notice of the profession in valvular *heart disease*. The effects on the system of convallarin and convallamarin have been investigated by H. Marmé of Germany, with the following results: *Convallarin*, in doses of 3 to 4 grains, acts as a purgative without observable inconvenience to the animals acted on; *convallamarin*, even in small doses, produces active vomiting, whether given by the mouth or injected into the subcutaneous tissue or directly into the veins. The latter principle acts especially on the heart, at first diminishing the number of its pulsations, and afterwards rendering them more frequent and irregular, and causing death in a few minutes after the introduction of the poison. The heart appears to be paralyzed, and cannot be excited after death. The principle acts on the heart through the vagi nerves. From 6 to 8 milligrammes (one-tenth to one-eighth of a grain) cause death when injected into the cervical vein in rabbits. (N. Y. M. J., 1867; S. Jb., 1867, v.) The physiological action of convallamarin has been investigated by a number of observers, with contrary results. Sée finds that in the dog it slows the action of the heart and increases the blood pressure decidedly, while Leubuscher states that its medicinal use does not elevate the arterial pressure. Ott, Coze, and Simon find that the heart is arrested in systole; Sée, that the arrest is diastolic; while Löwenthal, using the same preparation in exactly the same manner and dose upon different animals of the same species, obtained diverse results. Nathanson asserts that the confusion is largely due to the impurity

and lack of genuineness in the products used, even Merek having admitted the impurity of his commercial convallamarin. Nathanson found that convallarin produced in man, when given in doses of 0.06 to 0.12 gramme, three or four times daily, only nausea, diarrhoea, and gastric pain, while convallamarin administered in daily amounts, gradually increasing from 0.03 to 0.3 gramme, reduced the rate of the pulse and markedly increased the flow of urine, only in very rare cases causing nausea or vomiting. J. H. Andrews (Ph. Rev., March, 1898) reports a case in which a teaspoonful of the fluidextract of convallaria produced, in a child two years old, stupor with tremors and convulsions, dilated pupils, fall of temperature, rapid feeble pulse, rapid respiration, without gastric intestinal irritation, diuresis and diaphoresis; the patient recovered. In cardiac dropsy Sée gives, of an aqueous extract of the whole plant, 15 to 23 grains a day; Bojowlewsky each day 50 to 100 grains of the plant in infusion. (See *Fluidextractum Convallariæ*.)

Dose (U. S. P.), seven and a half grains (0.5 Gm.), but the root is never used medicinally.

Off. Prep.—Fluidextractum Convallariæ, U. S.

COPAIBA. U. S., Br.

COPAIBA [Balsam of Copaiba, Copaiva]

(co-pā'ī-bā)

"An oleoresin derived from one or more South American species of *Copaiba*¹ (Fam. *Leguminosæ*)." U. S. "The oleo-resin obtained from the trunk of *Copaifera Lansdorfii*, Desf., and other species of *Copaifera*, Linn." Br.

Balsamum Copaiferarum; Balsam Copaiba. Balsam Capivi; Copahu, Fr. Cod.; Oleo-résine (Baume) de Copahu, Fr.; Balsamum Copaivæ, P. G.; Copaiva; Copaiabalsam, G.; Balsamo di copaive, It.; Copaiba, Balsamo de copaiva, Sp.

Copaiba was first noticed in a work published by Purchas, in England, in 1625. The next reference to it was by Cristoval d'Acuña, in 1638. In 1648, Maregraf and Piso gave a detailed account of the tree which produces it, and the methods of gathering it. Jacquin in 1763 described a species of *Copaifera*, growing in Martinique, which he named *C. officinalis*. As this was believed to be the same plant with the one observed by Maregraf in Brazil, it was adopted in the Pharmacopœias, but their identity was denied; and Desfontaines proposed for Jacquin's species the title of *C. Jacquinii*, in honor of that botanist. It is now known that many species of *Copaifera* exist in South America, and all of them, according to Martius,

¹ The change of the generic name from *Copaifera* to *Copaiba* is another sacrifice to botanical reform. H. H. Rusby very properly says that this reform, as embodied in Kuntze's *Revisio Generum*, "will cause complete confusion." The generic records are said to be as follows: *Copaiba*, Mill., *Gard. Dict.* (1739); *Copaiva*, L., *Mat. Med.* (1749), *Adæ O. Kuntze*; *Copaifera*, L., *Gen.* (1762), *Adæ O. Kuntze*. It is to be hoped that the next Botanical Congress will decide upon names which will stand a reasonable length of time.

yield copaiba. Besides *C. officinalis* or *C. Jacquinii*, the following are described by Hayne: *C. guianensis*, *C. Langsdorffii*, *C. coriacea*, *C. Beyrichii*, *C. martii*, *C. bijuga*, *C. nitida*, *C. laxa*, *C. cordifolia*, *C. Jussieu*, *C. Sellowii*, *C. oblongifolia*, and *C. multijuga*. Hayne believed that *C. bijuga* was the plant seen by Maregraf and Piso. The four species to which in the Pharmacographia the production of copaiba is especially attributed are *C. officinalis*, L., *C. guianensis*, Desf., *C. coriacea*, Mart., and *C. Langsdorffii*, Desf.

C. officinalis is a native of Venezuela, and grows in the province of Carthagena, mingled with the trees which afford the balsam of Tolu. It grows also in some of the West India islands, particularly Trinidad and Martinique. Though recognized in earlier editions of the U. S. Pharmacopœia as a source of copaiba, it probably yields little of that now in use. According to Hayne (x. t. 17 f. c.), the species from which most of the copaiba of commerce is derived is *C. multijuga*, growing in the Brazilian province of Para. It was recognized by the U. S. P. 1870; but Bentham, after examining the only specimens extant, asserted that it is not a Copaifera at all. It is probable that *C. guianensis*, which inhabits the neighboring territory of Guiana, especially in the vicinity of the Rio Negro, affords also considerable quantities; and *C. Langsdorffii* and *C. coriacea*, which are natives of the province of Sao Paulo, are thought to yield most of the juice collected in that section of Brazil. *C. nitida*, inhabiting the province of Minas Geraes, probably also contributes to the commercial supplies through the port of Rio Janeiro.

Numerous varieties of true South American copaiba exist in commerce, known under the name of the various ports of shipment. The most important of these varieties are Bahia, Carthagena, Maracaibo, Maranhã, Para, Cayenne. Each one of these varieties has been referred (see *P. J.*, 1901, lxvi. 325) to a special species of the genus *Copaiba*, but there is little reason for supposing that this reference is accurate, and there is much reason for believing that various trees contribute to a single variety of copaiba. The following table according to the researches of Umney and Bennett shows the specific gravities and percentage of oil of the five most important of these copaibas:

Name.	Sp. gr.	Per cent. of oil.	Resin.
Bahia	0.988	49.7	Soft.
Carthagena	0.970	41.3	Brittle.
Maracaibo	0.969	42.5	{ Firm, but not easily pulverized.
Maranhã	0.990	41.8	Brittle.
Para	0.920	62.4	Very soft.

All of the above varieties answered to the solubility and Gurjun balsam tests.

It will be noticed at once that the Para and Bahia specimens examined by Umney failed to comply with the tests of the U. S. Pharmacopœia (1890), and yet, supposing that the

oil represents the chief therapeutic principle of copaiba, these varieties lead all the others. The German Pharmacopœia requires that the specific gravity shall be 0.98 to 0.99, and that the acid number shall fall between 75.6 and 84, and the ester number be not more than 8.4. Dieterich. (*P. J.*, April, 1899, and March, 1900.) *Surinam copaiba* is a yellowish or brownish-yellow liquid, varying from thick to thin in consistence; it may be distinguished from Maracaibo copaiba by the fact that one drop of it dissolved in 1 Cc. of acetic anhydride gives a fine blue color on the addition of a drop of sulphuric acid. (*P. J.*, Nov. 1904.)

According to E. Keto, copaiba of Maracaibo has a density of 0.999; a coefficient of acidity of 85.4; of etherification of 6.7; while that of Para has a density of 0.92; a coefficient of acidity of 19.4; of etherification of 7.4.

The juice is obtained by making a square chamber in the stems of the trees, reaching to the very centre; and the operation is said to be repeated several times during the same season. It is asserted that a single tree will yield about eighty-four English Imperial pints. As it flows from the wound, it is clear, colorless, and very thin, but it soon acquires a thicker consistence, and a yellowish tinge. It is most largely collected in the provinces of Para and Maranhã, in Brazil, and is brought to this country from the port of Para, in small casks or barrels. Large quantities of it come from Maracaibo, in Venezuela, and from other ports on the Caribbean Sea, whence it is brought in casks, demijohns, cans, jugs, etc. The drug is also exported from Angostura, Cayenne, Rio Janeiro, and some of the West India islands.

Properties.—Copaiba is a clear, transparent liquid, usually of the consistence of olive oil, of a pale yellow color, a peculiar not unpleasant odor, and a bitterish, hot, nauseous taste. Its sp. gr. varies ordinarily from 0.950 to 1.000, but has been known to be as low as 0.916. (Procter, *A. J. P.*, xxii. 292; "from 0.916 to 0.993." *Br.*) It is insoluble in water, but entirely soluble in absolute alcohol, ether, and the fixed and volatile oils. Strong alkaline solutions dissolve it perfectly; but the resulting solution becomes turbid when largely diluted with water. With the alkalies and alkaline earths it forms saponaceous compounds, in which the resin of the copaiba acts the part of an acid. It dissolves magnesia, especially with the aid of heat, and even disengages carbon dioxide from the carbonate of that earth. If triturated with a sixteenth of its weight of magnesia and set aside, it gradually assumes a solid consistence, and a similar change is produced with calcium hydroxide. *Solid Copaiba* or *Mass of Copaiba* was official in the U. S. P. 1890.¹ The essential constituents of copaiba are

¹ *Massa Copaibæ*, U. S. P. (1890), *Mass of Copaiba* [*Solidified Copaiba*]; *Pilulæ Copaibæ*, U. S. 1870; *Pilules de Copahu*, *Fr.*; *Copaiva-Pillen*, *G.*—"Copaiva, ninety-four grammes [or 3 ounces av., 138 grains]; Magnesia, six grammes [or 93 grains]; Water, 1

volatile oil and resin,¹ with at times small quantities of acids. As it contains no benzoic acid, it cannot with propriety retain its old title of *balsam of copaiba*. The substances which it most closely resembles, both in composition and in properties, are the turpentine. (See *Oleum Copaibæ*.) For a description of an apparatus for distilling the volatile oil, see a paper by R. A. Cripps in *C. D.*, 1892, 282. Cripps found commercial copaiba to contain the following percentages of volatile oil: 40.95, 45, 45.3, 46.4, 47.8, 48.2, 49.6, 50.4, 50.8, 53.3, 59.6. J. C. Umney (*A. J. P.*, 1893, 544) found in African copaiba 39 per cent. of an oil of 0.918 specific gravity and with a rotation of $+20^{\circ}$ $42'$, the last character distinguishing it from the other varieties which yield lævo-rotatory oils.

"A pale yellow to brownish-yellow, more or less transparent and viscid liquid, sometimes fluorescent; having a peculiar, aromatic odor and a persistent, bitter and acrid taste. Specific gravity: 0.950 to 0.995 at 25° C. (77° F.). Insoluble in water; soluble, or showing at most a slight opalescence, in absolute alcohol, carbon disulphide, petroleum benzin, and in fixed and volatile oils; completely soluble in chloroform and ether. When heated on a water-bath, it should evolve no odor of turpentine, and after forty-eight hours should leave a resinous mass weighing not less than 50 percent. of its original weight. One Gm. of Copaiba, when dissolved in 50 Cc. of alcohol, should require not less than 2.3 Cc., and not more than 2.8 Cc. of half-normal alcoholic potassium hydroxide for neutralization, using 1 Cc. of phenolphthalein T.S. as indicator (presence of a normal proportion of *acid resin*)."

When 4 drops of nitric acid (sp. gr. 1.40) and 1 Cc. of glacial acetic acid are mixed in a test-tube, and 4 drops of Copaiba are carefully poured on top of the liquid, no reddish zone should appear; nor should the fluid assume a red or purple color after being shaken

(absence of *gurjun balsam*). If 5 Cc. of Copaiba be shaken with 15 Cc. of alcohol, and heated to boiling for one minute, no drops of oil should separate after cooling and standing for an hour (absence of *paraffin oils*). If 20 drops of Copaiba be boiled with 1 Cc. of an alcoholic potassium hydroxide solution (1 in 10) for two minutes and cooled, and then twice its volume of ether be added to the liquid, no gelatinization should occur (absence of *fixed oils*). If 1 Gm. of Copaiba be shaken with 10 Cc. of ammonia water in a stoppered vial, and allowed to stand for twenty-four hours, the liquid will become turbid, but it should not gelatinize, nor should a firm mass be formed (limit of *resin*)."
U. S. "The volatile oil should be present to the extent of at least 40 per cent., should rotate the plane of a ray of polarized light from 28° to 34° to the left (absence of African copaiba), and should not boil under 482° F. (250° C.)." Br.

The resinous mass which remains after the distillation of the oil is hard, brittle, translucent, greenish brown, and nearly destitute of odor and taste. By mixing it with the oil in proper proportion, we may obtain a liquid identical or nearly so with the original juice. This resinous mass is of an acid character, and yields a series of amorphous salts; it may be obtained pure by exposing a mixture of 9 parts of copaiba and 2 parts of aqueous ammonia (sp. gr. 0.95) to a temperature of 10° C. In this way crystals of *copaivic acid*, $C_{20}H_{30}O_2$, are obtained. This acid agrees with the *abietic acid* of resin in composition, but not in properties. Copaivic acid is readily soluble in alcohol, and especially in warmed copaiba itself; much less soluble in ether. When recrystallized from alcohol, copaivic acid fuses at 116° to 117° C. (241° to 242.6° F.). (*A. J. P.*, 1879, p. 305.)

An analogous substance, *oxycopaivic acid*, $C_{20}H_{28}O_3$, was found in 1841 by H. von Fehling in Para copaiba, and Strauss in 1865 extracted *meta-copaivic acid*, $C_{22}H_{34}O_4$, from Maracaibo copaiba. Copaivic acid forms crystallizable salts with alkalies, and *sodium copaivate*, $NaC_{20}H_{30}O_2$, made by combining molecular quantities of the acid and soda, is asserted by Zlamál and Roquette to be more efficient than any other preparation of copaiba. Tschirch (*Harze und Harzbehälter*, 1900, p. 297) obtained from Maracaibo balsam a crystalline resin acid corresponding in many respects with Strauss's metacopaivic acid, to which, however, he gave the formula $C_{11}H_{18}O_2$ finding a melting point 89° to 90° C. as against 205° to 206° for Strauss's acid. Para balsam was found by Tschirch to contain two crystallizable resin acids together with several uncrystallizable ones. African copaiba balsam he found to contain a characteristic acid to which he gave the name *Illurinic acid* and the formula $C_{14}H_{20}O_2$ or possibly $C_{21}H_{30}O_3$. Keto, who worked out the preceding results jointly with Tschirch, has since published some additional results (*J.*

sufficient quantity. Triturate the Magnesia with a little Water, in a capsule, until the powder is uniformly dampened throughout. Then gradually incorporate with it the Copaiba, so that a uniform mixture may result, place the capsule on a water-bath, and heat during half an hour, frequently stirring. Lastly, transfer the mixture to a suitable vessel, and set this aside until the mass has acquired a plular consistence." U. S. 1890. See U. S. D., 18th ed. p. 854.

¹ *Resina Copaibæ*, U. S. P. (1890), *Resin of Copaiba*. "The residue left after distilling off the volatile oil from Copaiba." U. S. Schweitzer first obtained from Copaiba resin *copaivic acid*, which, analyzed by H. Rose, was found to have the formula $C_{20}H_{30}O_2$. When crystallized from alcohol the acid fuses at 116° to 117° C. (240.8° to 242.6° F.). Another acid, *oxycopaivic*, was obtained by von Fehling, and still a third, *metacopaivic acid*, by Strauss. The first of these has the formula $C_{20}H_{28}O_3$, and the second $C_{22}H_{34}O_4$. It is officially described as "a yellowish or brownish-yellow, brittle resin, having a slight odor and taste of copaiba. Soluble in alcohol, ether, chloroform, carbon disulphide, benzol, or amyl alcohol." U. S. 1890. Bernatzik exhibited nearly four drachms of this resin in five hours, causing violent gastro-intestinal irritation, with vomiting and purging, besides renal disturbance. The resin is eliminated by the urine, and exerts some influence upon the genito-urinary mucous membrane. It is, however, inferior to either the volatile oil or the balsam. Dose, from ten to twenty grains (0.65 to 1.3 Gm.).

P. C., 1902, p. 381). He finds in Para balsam the two crystallizable acids referred to above, one of which he names *paracopaibic acid* with the formula $C_{20}H_{32}O_3$ and fusing point 142° to 145° C., and the other *homoparacopaibic acid*, $C_{18}H_{28}O_3$, fusing at 111° to 112° C. To *illurinic acid* mentioned by Tschirch he gives the formula $C_{20}H_{32}O_3$ and the melting point 128° C.

Copaiba, upon exposure to the air, acquires a deep color, a thicker consistence, and greater density, and, if spread out upon an extended surface, ultimately becomes dry and brittle. This change is owing partly to the volatilization and partly to the oxidation of the essential oil. As it is the soft resin that results from the oxidation of the oil, it follows that the proportion of this resin increases with age. Considerable diversity must, therefore, exist in the drug, and in its physical properties and in the proportions of its ingredients, according to its age and degree of exposure. Similar differences also exist in the copaiba procured from different sources. Thus, that of the *West Indies*, when compared with the *Brazilian*, which is the variety above described, and in common use, is of a thicker consistence, of a deeper or darker yellow color, less transparent, and of a less agreeable, more terebinthinate odor; and specimens obtained from the ports of Venezuela and Colombia were found, upon examination by Vigne, to differ from each other not only in physical properties, but also in their chemical relations. (*J. P. C.*, N. S., i. 52.) The same is true, as observed by Buignet, of their action on polarized light, in which they differ not only in degree, but sometimes also even in direction. (*J. P. C.*, Oct. 1861, pp. 266-7.) It is not impossible that differences may exist in the juice according to the circumstances of its collection. The species of *Copaifera* from which the juice is collected, as well as the age of the tree, its position, and the season of collection, must also have influence over the product. It is highly probable that the resinous matter results from the oxidation of the oil in the cells of the plant, and that the less elaborated the juice may be, the larger proportion it will contain of the oil. It is said that a volatile oil flows abundantly from a tree near Bogota, which is employed to adulterate the copaiba collected in that vicinity and shipped from Maracaibo and other neighboring ports.¹

¹ *African Copaiba*, or *Balsam of Illurine*, which reached the London market first in 1891, from West Africa, is a brownish substance, having a consistency similar to the Maracaibo copaiba, and a greenish fluorescence. Its aromatic odor is entirely different from that of copaiba; its taste is biting, with an after-taste of bitterness. According to Keto (*J. P. C.*, 1902, 381) its density is 0.9905; its coefficient of acidity 55.5; of etherification 8.3. It is soluble in chloroform and petroleum benzin, also in ether, with which it makes an opalescent liquid. Its solution in absolute alcohol, or alcohol of 95 percent, is not limpid. From it Keto separated *illurinic acid*. Its volatile oil is of a pale yellow color, with a strong odor entirely different from that of copaiba. The residue which remains after the distillation consists of two resins, one soluble, the other insoluble, in alcohol. This oleoresin probably shares the medicinal proper-

Adulterations.—Copaiba is often adulterated² with a fixed oil, especially castor oil, which, in consequence of its solubility, cannot, like the others, be detected by alcohol. Various plans have been proposed for recognizing the castor oil. The simplest is to boil a drachm of the copaiba in a pint of water until the liquid is wholly evaporated. If the copaiba contains a fixed oil, the residue will be more or less soft, according to the quantity present; otherwise it will be hard. Magnesium carbonate, potassium hydroxide, and sulphuric acid have also been proposed as tests. In the late Edinburgh Pharmacopœia it was stated that copaiba "dissolves a fourth part of its weight of magnesium carbonate, with the aid of a gentle heat, and continues translucent." The presence of a small proportion of any fixed oil renders the mixture opaque. One part of potassium hydroxide dissolved in two of water forms a clear solution with nine parts of pure copaiba, and the liquid continues clear when moderately diluted with water or alcohol; but the presence of one-sixth of fixed oil in the copaiba occasions more or less opacity in the liquid, and half the quantity causes the precipitation of white flakes in a few hours. (Stolze.) Turpentine, which is said to be sometimes added to copaiba, may be detected by its odor, especially if the copaiba be heated. According to Redwood, most of the proposed tests of the purity of copaiba are liable to fallacy, and the best measure of its activity is the quantity of volatile oil it affords by distillation. Castor oil, Venice turpentine, linseed oil, or gurgum balsam may be detected by means of petroleum benzin, which makes a clear solution with pure copaiba, but if either of the substances mentioned be present a milky mixture, which soon settles into two layers, is formed, the copaiba solution being on top (*A. J. P.*, July, 1873; *Proc. A. Ph. A.*, xxiv. 191, xxvi. 286). Maisch has found that ten volumes of petroleum benzin, instead of three as proposed by Wayne, must be added to one of copaiba to get the best results from this test. Indeed; it has been shown that pure copaiba will sometimes show turbidity when mixed with petroleum benzin. (*A. J. P.*, 1877, p. 131.) Hager recommends the use of absolute alcohol, which he says completely dissolves, without turbidity, all the varieties of copaiba except the Para, whose solution on standing clears itself by the deposition of a few white flakes. J. M. Fulton asserts that some pure copaibas are not entirely dissolved by absolute alcohol. (*A. J. P.*, 1877.) For additional tests and criticisms by Beckurts and Brueche, see *A.*

ties of true copaiba, being the product of *Hardwickia Mannii*, a tree closely allied to the true *Copaibas*.

² Some years since, a substance was imported into New York, under the name of *red copaiba*, which did not possess a single characteristic of the genuine drug. It was of a thick, semi-fluid consistence, not unlike that of balsam of Tolu, as it often reaches us, of a brown color similar to that of the same balsam, though darker, and of an unpleasant yet somewhat aromatic odor, recalling that of Liquidambar, but less agreeable. Its origin is unknown.

Pharm., 1891, p. 90; also *Proc. A. Ph. A.*, 1892, 635. For Hager's test, see *C. D.*, 1894, 740. Dodge and Oleott (*Am. Drug.*, 1895, 5) describe a test to detect gurjun balsam in copaiba, which Kebler regards as the most reliable yet proposed; it is as follows. Four drops of the suspected sample, dissolved in half a fluidounce of glacial acetic acid, will, if pure, remain colorless and clear, or but slightly cloudy, if from four to six drops of pure nitric acid be dropped into the solution. If the sample be pure gurjun balsam, the mixture will have a deep purple color; if a mixture of the two balsams, the depth of color will vary according to the amount of the adulterant, as small a proportion as 2 per cent. being discoverable; this test is now official. (See also *A. J. P.*, 1896, 143, and 1897, 394.) For a valuable paper on Copaiba by A. R. L. Dohme see *Proc. A. Ph. A.*, 1904, 322.

Uses.—Copaiba is gently stimulant, diuretic, laxative, and in very large doses often actively purgative. It produces, when swallowed, a sense of heat in the throat and stomach, and extends an irritant action not only throughout the alimentary canal, but also to the urinary passages, and in fact, in a greater or less degree, to the whole mucous membrane, for which it appears to have a strong affinity. The urine acquires a peculiar odor during its use, and its odor may be detected in the breath. It sometimes occasions an eruption upon the skin resembling that of measles, and attended with disagreeable itching and tingling, or even violent pemphigus. (*N. Y. M. J.*, Jan. 1873, p. 416.) Nausea and vomiting, painful purgation, strangury and bloody urine, and a general state of fever are caused by excessive doses. As a remedy it has been found most efficient in diseases of the mucous membrane, particularly those of a chronic character. Thus, it is given with occasional advantage in *leucorrhæa*, *chronic cystitis*, *chronic dysentery*, *diarrhæa*, *hemorrhoids*, *chronic bronchitis*, and *psoriasis*. The complaint, however, in which it is most employed is *gonorrhæa*. It should not be administered in the first stages, when the inflammation is severe and acute, nor is it applicable to very chronic forms of the disorder, such as gleet. It was formerly much esteemed as a vulnerary, and as an application to *ulcers*, but it is now seldom used externally. Ruschenberger recommends it locally in *chilblains*. (*Med. Examiner*, i. 77.)

Both the volatile oil and the resin are eliminated by the kidneys in an altered condition; if to the urine of a person taking the drug, nitric acid be added, a precipitate is thrown down, which may be mistaken for albumin. The volatile oil is more active than is the resin, which is not, however, inert. Wilks of Guy's Hospital, London, speaks of the resin with great confidence as a hydragogue diuretic in obstinate *dropsy*, given in the dose of fifteen or twenty grains three times a day.

Dose, of copaiba, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.) three times a

day, or a smaller quantity repeated more frequently. It may be given dropped on sugar, but in this form is often so exceedingly offensive as to render some concealment of its nauseous qualities necessary. A less disagreeable form is that of emulsion, prepared by rubbing the copaiba first with mucilage, or the yolk of an egg, and sugar, and afterwards with some aromatic water, as that of mint or cinnamon. The *volatile oil*, which is official, may be given in the dose of ten or fifteen minims (0.6 to 0.9 Cc.) in emulsion, or, as is almost universally preferred, in capsules.

CORIANDRUM. U. S. (Br.)

CORIANDER [Coriander Seed]

(cō-rī-ăn'drūm)

"The dried ripe fruit of *Coriandrum sativum* Linné (Fam. *Umbellifere*)."
U. S. "The dried ripe fruit of *Coriandrum sativum*, Linn." Br.

Coriandri Fructus, Br.; Coriander Fruit; Coriandre, Fr. Cod.; Korlander, G.; Coriandro, It.; Cilantro, Sp.

Coriandrum sativum, Willd., *Sp. Plant.* i. 1448; Woodv., *Med. Bot.*, 137, t. 53.—This is an annual plant, with an erect, round, smooth, branching stem rising about two feet, and furnished with compound leaves, of which the upper are thrice ternate, with linear pointed leaflets, the lower pinnate, with the pinnæ cut into irregular serrated lobes like those of parsley. The flowers are white or rose-colored, and in compound terminal umbels; the fruit globular, and composed of two concave hemispherical portions. *C. sativum* is a native of Italy, but at present grows wild in most parts of Europe, having become naturalized in consequence of its extended cultivation. The flowers appear in June, and the fruit ripens in August. It is a singular fact that all parts of the fresh plant are extremely fetid when bruised, while the fruit becomes fragrant by drying. This is the official portion. It is brought to us from Europe.

The fruit of the coriander is globular, about an eighth of an inch in diameter, obscurely ten-ribbed, with minute indications of secondary ribs in the furrows, of a grayish or brownish-yellow color, and separable into the two mericarps (half-fruits), which are only bound together by the membranous pericarps. Each half-fruit is provided with two oil tubes on the conjoining face. The whole fruit has the persistent calyx at its base, and is sometimes surmounted by the adhering conical style. Coriander is thus described by the U. S. Pharm.: "Nearly globular, brownish-yellow, smooth, 4 to 5 Mm. in diameter, crowned with the calyx teeth and a short stylopodium; mericarps usually united, each with five prominent, straight primary ribs and four indistinct secondary ribs, the inner surface deeply concave and with two oil-tubes; odor and taste agreeably aromatic." U. S. The aromatic taste and odor depend on a *volatile oil*, which may

be obtained separate by distillation. One pound of the seeds yields forty-two grains of the oil. (Zeller.) This is colorless or pale yellow, with an agreeable odor of coriander, a mild aromatic taste, and a sp. gr. varying from 0.87 to 0.88. Its main constituent, according to Semmler (*Ber. d. Chem. Ges.*, xxiv. 206), is what was first called *coriandrol*, is now recognized as right rotatory *linalool*, $C_{10}H_{18}O$, boiling between 194° and 198° C. Besides this, about 5 per cent. of *dextro-pinene* was isolated, boiling between 156° and 160° C. It is one of the most permanent volatile oils, long resisting oxidation. The fruit's virtues are imparted to alcohol by maceration, and less readily to water.

Uses.—Coriander is a rather feeble aromatic. It is almost exclusively employed in combination with other medicines, either to cover their taste, to render them acceptable to the stomach, or to correct their griping qualities. It was well known to the ancients.

Dose, twenty to sixty grains (1.3 to 3.9 Gm.).

CREOSOTUM. U. S., Br.

CREOSOTE

(crê-q-sô'tûm)

"A mixture of phenols and phenol derivatives, chiefly guaiacol and creosol, obtained during the distillation of wood-tar, preferably of that derived from the beech, *Fagus silvatica* Linné or *Fagus ferruginea* Aiton (Fam. *Fagaceæ*)." *U. S.* "A mixture of guaiacol, creosol, and other phenols; obtained in the distillation of wood-tar." *Br.*

Creosotum, *Br.* (1885); Creasote; Créosote du Goudron de Bois, *Fr. Cod.*; Créosote, *Fr.*; Kreosotum, *P. G.*; Kresot, Buchenholztheerkresot, *G.*; Creosoto, *It.*; Creosota, *Sp.*

This is a substance discovered in 1830 by Reichenbach in the products of the distillation of wood. This distillation of wood yields products very analogous to one fraction of the coal tar obtained by the destructive distillation of bituminous coal. This fraction is the heavy oil of coal tar, which comes over between 165° C. (329° F.) and 200° C. (392° F.): it is often called "*coal tar creosote*," and contains a group of phenols, including carbolic acid, now known officially as *phenol*, C_6H_5O , boiling at a temperature not higher than 188° C. (370.4° F.), *cresylic acid*, or *cresol*, C_7H_8O , boiling at from 195° to 205° C. (383° to 401° F.), and *xylénol*, or *dimethyl phenol*, $C_8H_{10}O$, boiling at 211° C. (411.8° F.). Wood tar is a complex mixture of phenoloid bodies. These are chiefly the acid methylic ethers of catechol (or pyrocatechin) and its homologues. For chief constituents, see table page 403.

Preparation.—Creosote is obtained either from wood tar or from crude pyroligneous acid.

When wood tar is used, it is distilled until it has attained the consistence of pitch. The distilled liquid divides itself into three layers, an aqueous between two oily layers. The inferior oily layer, which alone contains the creosote, is separated, and saturated with sodium carbonate to remove acetic acid. The liquid is allowed to rest, and the new oil which separates is decanted from it. This oil is distilled, and yields products lighter than water, and a liquid heavier. The latter alone is preserved, and, after having been agitated repeatedly with weak phosphoric acid to neutralize ammonia, is allowed to remain at rest for some time. It is next washed until it is free from acidity, and then distilled with a fresh portion of weak phosphoric acid, care being taken to cohobate from time to time. The oily liquid thus rectified is colorless, and contains much creosote, but also a portion of light oil distillate. To separate the latter, the liquid is mixed with a solution of sodium hydroxide of the density 1.12, which dissolves the creosote, but not the light oil. The oil, which floats from its levity, is then separated, and the alkaline solution of the creosote is exposed to the air, until it becomes brown in consequence of the decomposition of a foreign matter, and is then saturated with sulphuric acid. This sets free the creosote, which is decanted, and again distilled. The treatment by solution of soda, sulphuric acid, etc., is to be repeated until the creosote no longer becomes brown by exposure to the air, but only slightly reddish. It is then dissolved in a stronger solution of soda, and distilled again, and finally redistilled for the last time, rejecting the first portion which comes over, on account of its containing much water, and collecting the next portion; care being taken not to push the distillation too far. The product collected is creosote.

When creosote is extracted from pyroligneous acid, the first step is to dissolve sodium sulphate in it to saturation. The oil which separates and floats above is decanted, and, having been allowed to remain at rest for a few days, is saturated by potassium carbonate with the assistance of heat, and distilled with water. The oleaginous liquid obtained is of a pale yellow color, and is to be treated as above detailed, in relation to the treatment of the corresponding oil obtained from wood tar.

Properties.—Creosote, when pure, is a colorless oleaginous liquid, of the consistence of oil of almonds, slightly greasy to the touch, volatilizable by heat, and having a caustic, burning taste, and a penetrating, disagreeable odor, like that of smoked meat, and analogous to, yet different from, that of phenol. As met with in commerce, it has frequently a brownish tinge. It burns with a sooty flame. Applied in a concentrated state to the skin, it corrugates and then destroys the cuticle, causing a white spot. On paper it leaves a greasy stain, which disappears in a few hours, or in ten minutes if heated to 100° C. (212° F.). Its sp.

gr. is not below 1.072 at 25° C. (*U. S.*), and not below 1.079 at 15.5° C. (*Br.*). It boils between 200° and 220° C., and remains fluid at -27° C. It is a non-conductor of electricity, and refracts light strongly. It is devoid of acid or alkaline reaction. Mixed with water, it forms two layers, one consisting of one part of creosote and about eighty of water, the other, of one part of water and ten of creosote. It dissolves a large proportion of iodine and phosphorus, and a considerable amount of sulphur, especially when assisted by heat. Allen states that in Rhenish creosote guaiacol predominates, while a sample of Morson's creosote from "Stockholm tar," examined by him, boiled at about 217° C., and consisted chiefly of cresol.

The U. S. Pharm. describes creosote as "an almost colorless, yellowish (not pinkish), highly refractive, oily liquid, having a penetrating, smoky odor, and a burning, caustic taste; it should not become brown in color on exposure to light. Specific gravity not below 1.072 at 25° C. (77° F.). Its solution in about 140 parts of water at 25° C. (77° F.) is not perfectly clear. With 120 parts of hot water it forms a clear liquid, which, on cooling, becomes turbid from the separation of minute oily drops (distinction from, and absence of, both *phenol* and so-called '*coal-tar creosote*'). The filtrate from these separated oily globules yields a reddish-brown precipitate with bromine T.S. (distinction from *phenol* and so-called '*coal-tar creosote*,' both of which yield white precipitates). Soluble in all proportions in absolute alcohol, ether, chloroform, carbon disulphide, acetic acid, and fixed and volatile oils. When distilled, most of it comes over between 200° and 220° C. (392° and 428° F.). When cooled to -20° C. (-4° F.), it becomes gelatinous, but does not solidify (difference from *phenol*). It is inflammable, burning with a luminous, smoky flame. Creosote is neutral or only faintly acid to litmus paper. On stirring together equal volumes of Creosote and collodion in a dry test-tube, no permanent coagulum should form (difference from *phenol* and so-called '*coal-tar creosote*,' and limit of the former). If 1 volume of Creosote be mixed with 1 volume of 95 percent. glycerin, a clear mixture will result, from which a creosotic layer, equal to or greater in volume than the Creosote employed, will separate on the addition of one-fourth volume of water (difference from, and limit of, *phenols*). On adding to 10 Cc. of a saturated aqueous solution of Creosote 1 drop

of ferric chloride T.S., the liquid develops a clear violet-blue color, which is very transient; it then clouds almost instantly, the color passing rapidly from a grayish-green into a muddy brown, with finally the formation of a brown precipitate (difference from *phenol* and so-called '*coal-tar creosote*,' and limit of the former). If 1 Cc. of Creosote be mixed with 10 Cc. of a solution of potassium hydroxide in absolute alcohol (1 in 5), a solid crystalline mass will form (difference from *phenol* and so-called '*coal-tar creosote*,' and limit of the former). On mixing 2 Cc. of Creosote with 10 Cc. of normal sodium hydroxide V.S., a clear, pale yellow liquid results, which remains unclouded on diluting with 50 Cc. of water (absence of *neutral oils*). If 1 Cc. of Creosote be cautiously and gently shaken with 2 Cc. of petroleum benzin and 2 Cc. of freshly prepared barium hydroxide T.S. until a uniform mixture is produced, upon complete separation three distinct layers are visible, the middle one of which contains the Creosote, unaltered in appearance; while the petroleum benzin should not be blue or muddy, and the aqueous layer should not have acquired a red tint (absence of *cærolignol* and some other high-boiling constituents of wood-tar)." *U. S.*

The British Pharm. describes Creosote as "a colorless or yellowish highly refractive liquid, having a strong empyreumatic odor and acrid taste; neutral or only faintly acid to litmus. It is dissolved by about 150 parts of water at ordinary temperatures, and is more soluble in hot water. It is freely soluble in alcohol (90 per cent.), ether, chloroform, glycerin, and glacial acetic acid. Specific gravity, not below 1.079. It distils between 392° F. (200° C.) and 428° F. (220° C.). A 1 per cent. solution in alcohol (90 per cent.), or a half per cent. solution in water, with a drop of the test-solution of ferric chloride, yields a green coloration, rapidly changing to a reddish brown. It rotates the plane of a ray of polarized light to the left. Dropped on white filtering paper and exposed to a temperature of 212° F. (100° C.), it leaves no translucent stain (absence of less volatile liquids). It is miscible with an equal volume of collodion without gelatinization; and, when shaken with 5 times its bulk of solution of ammonia, its volume should not be diminished materially (distinction from *phenol*)." *Br.*

Creosote instantly dissolves ammonia, and retains it with great force. Strong nitric and sulphuric acids decompose it, the former giving

(Allen's *Chem. Org. Anal.*, 2d ed., vol. II. p. 565.)

rise to reddish vapors, the latter to a red color, which becomes black on the addition of more of the acid. Diluted nitric acid converts it into a brown resin, which, treated with ammonia, and then dissolved in boiling alcohol, gives, by evaporation, certain salts of ammonia, two of which contain new acids, discovered by Laurent. Hydrochloric acid produces no change in it. Morson of London, gives a test based on the solvent power of glycerin over phenol, which is dissolved by it in all proportions, while pure creosote is insoluble or nearly so, and, consequently, if any liquid assumed to be creosote dissolves largely in glycerin, it probably consists in the whole, or in large part, of phenol. Subsequent experiments appear to show that this test succeeds best with Morson's creosote; beech-wood creosote, although pure, sometimes mixes with glycerin without turbidity. Hager modified Morson's test by using a mixture of 3 parts absolute glycerin and 1 part water. With this fairly good results are obtained, according to Allen. A still better test, according to John A. Clark, is an alcoholic solution of iron perchloride (*Tinct. Ferri Perchlor.*, Br.), which with an alcoholic solution of creosote produces a deep greenish-blue color, but with phenol a light brown. (*A. J. P.*, June, 1873, 269.) Creosote dissolves a large number of metallic salts, and reduces some of them to the metallic state, as, for example, silver nitrate and acetate. *Froehde's reagent* (a solution of 1 part of molybdic acid in 100 parts of sulphuric acid) is recommended by E. W. Davy as a distinguishing test for phenol (*P. J.*, 1878, 1022). A drop or two of the doubtful liquid is to be agitated with two fluidrachms of distilled water, the whole filtered, and a drop or two of the test solution added. Pure creosote gives a brown or reddish-brown reaction on standing or slight warming, passing to a light yellowish brown; with phenol, the brown passing to a maroon soon develops a more or less intense purple. Of all the properties of creosote, the most remarkable is its power of preserving meat. It is this property which has suggested its name, derived from *κρέας*, *flesh*, and *σώζω*, *I preserve*.

Impurities and Adulterations.—Creosote is sometimes adulterated with rectified oil of tar and the fixed and volatile oils. All these substances are detected by strong acetic acid, which dissolves the creosote, and leaves them behind, floating above the creosote solution. Creosote from beech-wood tar, however, is only partially dissolved by hot acetic acid of ordinary strength. Fixed oils are also discovered by a stain on paper not discharged by heat. Any trace of the matter which produces the brownish tinge is detected by the liquid becoming discolored by exposure to sunshine. Commercial creosote sometimes contains phenol and cresol, from coal tar; and, indeed, much of what has been sold for creosote was nothing more than impure phenol. (See *Phenol*.) It has been already stated that phenol strongly resembles creosote;

but, as the effects of the two on the system are very different, it is highly desirable to be able to distinguish between them. Tests for this purpose have been given above, and, with those quoted from the *Pharmacopœia*, are sufficient for the purpose. The large doses in which creosote is now sometimes given makes the sale of the so-called "coal tar creosote" dangerous, for there would be a strong probability that a patient might be given a large dose of phenol with disastrous effects; Merck & Co. have publicly announced that they have ceased to label or market "coal tar creosote."

Uses.—The constitution of even genuine beech-wood creosote varies very greatly in the proportion of guaiacol and cresol and in the amount of monophenols, and it would seem impossible to get under the name of creosote a fixed medicament. Nevertheless, for practical therapeutic purposes creosote is sufficiently constant in its composition, the physiological and therapeutic action of its various constituents being apparently so closely allied as to make variability in the proportion of these constituents of little importance; indeed, our knowledge of the physiological effects of creosote is very imperfect. It rivals phenol in its antiseptic power. It is, when applied locally, a paralyzant to the nerves, and probably to all higher tissues; and it was formerly generally believed to be almost identical in the range and powers of its activity with phenol. If it be true, however, as stated in *S. M.*, July, 1891, that Bouchard has administered it in doses of two and a half drachms without evil result, it cannot be physiologically equivalent to phenol. The correctness of this view is further indicated by the rarity of cases of creosote poisoning in the records of medicine. Freudenthal (*N. Y. M. R.*, April, 1892) reports the case of a woman who took 600 drops of creosote in a very short time, the ingestion being followed almost immediately by unconsciousness, with intense trismus, contracted immobile pupils, and general cyanosis, but in which recovery was made practically without the administration of remedies. He further states that subsequently this same patient, by increasing the dose of creosote, was able to take 500 drops daily without ill effect. Creosote was originally administered in *phthisis* with the idea of destroying the tubercle bacillus. There is, however, no reason for believing that it directly affects the growth of this organism, although it undoubtedly is a very effectual remedy in the disease. Its value is almost in direct proportion to the amount of expectoration,—i.e., to the activity of the catarrhal processes. It acts by influencing the pulmonic catarrh, which, although a secondary result of the bacillus, favors greatly their growth. It is at least of equal service in cases of chronic *non-tubercular inflammation* of the bronchial tubes, and even of the lung structure itself when the disease is of a catarrhal type. To be effective it must be given in as large doses

as the stomach can bear, and its use must be continually kept up for weeks and even months. It may be given in cod liver oil or emulsion, but is usually best tolerated in capsules (three to five minims each). Two of these may be administered at first four times a day, the dose being gradually increased until from thirty to forty minims a day are taken, or some evidences of disagreement with the digestion appear. The remedy should be taken after meals, or the ingestion should be immediately preceded by a glass of milk. Creosote has also been used hypodermically in phthisis. Thus, Perom employed a 10 per cent. solution given in oil of sweet almonds, two injections of eighty minims each being given daily. Dor administered, by intra-tracheal injections, a 5 per cent. solution in recently boiled olive oil, holding that the drug reached the pulmonic alveoli and attacked the disease locally. On account of its local action as a powerful paralyzant of nerve-tissue, creosote is frequently employed with great advantage in cases of *nausea, vomiting, or diarrhæa* dependent upon excessive irritability, without acute inflammation, of the gastric or intestinal mucous membrane; it has also been successfully used in the *vomiting of pregnancy* or of *hysteria*, in *cholera morbus, cholera infantum, bacillary diarrhæa, typhoid fever*, and even in *dysentery*. When in these cases there is a tendency to fermentation of the contents of the stomach or bowels, creosote is especially valuable, and may often be combined advantageously with an alkali or chalk. Externally, creosote has been employed for exactly the same diseases as has phenol. Indeed, the latter remedy, on account of its greater cheapness, has almost entirely supplanted creosote. The skin diseases to the treatment of which creosote has been supposed to be best suited are those of a scaly character. In *burns* its efficacy has been insisted on, especially in those attended with excessive suppuration and fungous granulations. In *chilblains* also it is stated to be a useful application. Mixed with four parts of lard, it is said to have proved very serviceable in *erysipelas*. When applied to wounds it acts as a hæmostatic, stopping the capillary hemorrhage, but possesses no power to arrest the bleeding from large vessels. Accordingly, creosote water has been applied locally in *menorrhagia*, and to arrest *uterine hemorrhage* and the bleeding from leech-bites. The ulcers in the treatment of which it has been found most useful are those of an indolent and gangrenous character, in which its several properties of escharotic, stimulant, and antiseptic are usefully brought into play. In all these cases, should the remedy cause irritation, it must be suspended, or alternated with emollient and soothing applications. Injected into fistulous ulcers, it proves a useful resource, by exciting the callous surfaces and disposing them to unite. Wherever there are foul ulcers, gangrenous surfaces, or inflamed serous, mucous, or glandular tissues giving rise to fetid dis-

charges, creosote may be substituted for phenol; as examples may be mentioned fetid *leucorrhæa*, puerperal *metritis*, fetid *otorrhæa*, putrid or *diphtheritic sore throat*, chronic *empyema*. The strength of the application may vary from that of pure creosote, to a single drop in a fluidounce of water, according to the delicacy of the part and the severity of the disease. On account of its local anæsthetic and antiseptic influence, it is much employed by dentists for the obtunding of sensitive dentine and as an ingredient of pastes for the destruction of nerves. One or two drops of the pure substance must be carefully introduced into the hollow of the tooth on a little cotton, avoiding contact with the tongue or cheek. To render it effectual, the hollow of the tooth must be well cleansed before it is applied. A mixture of 15 parts of creosote and 10 of collodion is said to have a jelly-like consistence, and to be usefully applied to carious teeth, which it protects from the air; but, as pure creosote does not coagulate collodion, this remark applies properly to the impure phenol before stated to be commonly sold under the same name.

In an overdose creosote acts as a poison, producing giddiness, obscurity of vision, depressed action of the heart, convulsions, and coma. H. A. Hare has found that sulphuric acid and the soluble sulphates are antidotal to creosote as they are to phenol. Medicinal treatment consists in evacuation of the poison and administration of ammonia and other stimulants.

Under the name of Vapor Creosoti (*Inhalation of Creosote*), the British Pharmacopœia (1885) formerly directed a preparation consisting of 12 minims of creosote and 8 fluid-ounces of boiling water, which were directed to be mixed in an inhaling apparatus, so arranged that the air should be made to pass through the solution, and then inhaled. It may be used in chronic inflammation of the air passages.

Dose, of creosote, five to ten minims (0.3 to 0.6 Cc.).

CRESOL. U. S.

CRESOL

(crēs'ol)

$C_7H_7.OH = 107.25$

"A mixture [$C_6H_4(CH_3)OH$] of the three isomeric Cresols obtained from coal-tar, freed from phenol, hydrocarbons, and water. It should be preserved in amber-colored bottles, protected from light." *U. S.*

Cresolum, Cresolum Parum; Cresylic Acid, Tricresol, Methylphenol, Oxytoluene; Cresol, *Fr.*; Euterol, Trikresol, Kresol, *Gr.*

Preparation.—Cresol was introduced into the U. S. P. (8th Rev.) mainly for use in making the official compound solution of cresol

(*Liquor Cresolis Compositus*), an antiseptic solution well adapted for external uses because of its miscibility with water. Crude carbolic acid is an impure form of cresol. Cresol is prepared from coal tar by collecting the distillates coming over between 140° C. and 220° C., and purifying these by treatment with solution of sodium hydroxide and hydrochloric acid.

Properties.—There are three isomeric cresols: *orthocresol*, melting at 31° C. and boiling at 188° C.; *metacresol*, a liquid boiling at 201° C., but not solidifying even at -80° C.; and *paracresol*, forming colorless prisms, melting at 36° C. and boiling at 198° C. These cresols are all obtainable by fractional distillation from that portion of coal tar boiling between 190° and 210° C.¹ Cresol of the U. S. P. is "a colorless or straw-colored refractive liquid, having a phenol-like odor, and turning yellowish-brown on prolonged exposure to light. Specific gravity: 1.038 at 25° C. (77° F.). Cresol is soluble in 60 parts of water at 25° C. (77° F.); miscible in all proportions with petroleum benzin, benzene, alcohol, ether, and glycerin; miscible with alkali hydroxide solutions. It boils at from 195° to 205° C. (383° to 401° F.). If 1 Cc. of Cresol be mixed with 1 Cc. of an aqueous solution of sodium hydroxide (1 in 10), it should dissolve with no appreciable liquid residue (absence of, or limit of, *hydrocarbons*). If 1 Cc. of Cresol be mixed with 1 Cc. of glycerin, a clear solution should be produced, from which, on the addition of 1 Cc. of water, the Cresol should completely separate (absence of, and distinction from, *phenol*)." U. S.

Uses.—It is generally believed that cresol is much more active as a germicide than phenol. The statement that it is less toxic than is phenol is probably not correct, although the difficulty of the absorption of cresol makes it act more slowly than does phenol, and it is certainly less caustic. The symptoms of poisoning by it have been identical with those of phenol poisoning. Internally cresol has been used to some extent given in capsules, but is inferior to phenol and has the same range of application. For further information see Cresol preparations, PART II.

Dose, 2 to 3 minims (0.12 to 0.2 Cc.).

Off. Prep.—*Liquor Cresolis Compositus*, U. S.

CRETA PRÆPARATA. U. S., Br.

PREPARED CHALK

(crē'ta præ-pa-rā-ta)

$\text{CaCO}_3 = 99.35$

"Native Calcium Carbonate, freed from most of its impurities by elutriation." U. S., Br.

Creta Lavigata; Craie lavée, Craie préparée, Fr.; Präparirte Kreide, Schlämmkreide, G.; Creta præparata, Sp.

¹ *Tri-kresol* is a mixture of orthocresol 35 per cent., metacresol 40 per cent., and paracresol 25 per cent.

Preparation.—Calcium carbonate, in the extended meaning of the term, is the most abundant of simple minerals, constituting, according to its state of aggregation and other peculiarities, the different varieties of calcareous spar, common and shell limestone marble, marl, and chalk. It occurs also in the animal kingdom, forming the principal part of shells, and a small proportion of the bones of the higher orders of animals. It is present in small quantity in most natural waters, being held in solution by the carbon dioxide which they contain. In the waters of limestone districts it is a very common impregnation, and causes purging in those not accustomed to its use. In all such cases, boiling the water, by expelling the carbon dioxide, causes the carbonate to be deposited. It has been shown, however, that calcium carbonate is itself in a slight degree soluble in water; so that a small proportion remains in limestone water which has been long exposed to boiling. That the carbonate is not held in solution by free carbon dioxide is shown by the fact that lime water causes no precipitation. (*J. P. C.*, 4e sér., iii. 147.) Besides being official in the state of chalk, calcium carbonate is also ordered as it exists in marble and oyster shell, and as obtained by precipitation. Chalk occurs abundantly in the south of England and the north of France. It exists massive in beds, and very frequently contains nodules of flint, and fossil remains of land and marine animals. According to F. V. Hayden, chalk beds identical with those of Europe extend for 400 miles along the Missouri River in Dakota. Chalk is an insipid, inodorous, insoluble, opaque, soft solid, generally white, but grayish white when impure. It is rough to the touch, easily pulverized, and breaks with an earthy fracture. It soils the fingers, yields a white trace when drawn across an unyielding surface, and when applied to the tongue adheres slightly. Its sp. gr. varies from 2.3 to 2.6. It is never a perfectly pure calcium carbonate, but contains, besides gritty silicious particles, small portions of alumina and ferric oxide. If pure, it is entirely soluble in hydrochloric acid, but usually a little silica is left. If this solution be not precipitated by ammonia, it is free from alumina and iron. Chalk, on account of the gritty particles which it contains, is unfit for medicinal use until it has been reduced to a very fine powder. The mineral, previously pulverized, should be rubbed with a little water upon a porphyry slab, by means of a muller of the same material. Having been thus very minutely divided, it is agitated with water, which upon standing a short time deposits the coarser particles, and, being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation*, the latter *elutriation*. The soft mass which remains after the decanting of the clear liquor is made to fall upon an absorbent surface in small portions, which when dried have a conical

shape.¹ Practically, prepared chalk is generally made on the large scale from *whiting* by the manufacturer. (See *P. J.*, vii. 146.)

Properties.—"A white to grayish-white, very fine amorphous powder, often moulded into conical drops; odorless and tasteless; permanent in the air. Almost insoluble in water; insoluble in alcohol; soluble in diluted acetic, hydrochloric, or nitric acids, with copious effervescence, leaving not more than a trifling residue. When heated to full redness, Prepared Chalk gradually loses carbon dioxide, and is converted into calcium oxide." *U. S.*

Uses.—This is the only form in which chalk is used in medicine. It is an excellent antacid; and, as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to *diarrhæa* accompanied with acidity. It is also sometimes used in acidity of stomach attending *dyspepsia* and *gout*, when a laxative effect is to be avoided, and it is one of the best antidotes for oxalic acid. It has been employed as an application to *burns* and *ulcers*, which it moderately stimulates, while it absorbs the ichorous discharge and thus prevents it from irritating the diseased surface or the sound skin. It is given internally in the form of powder, or suspended in water by the intervention of gum arabic and sugar. (See *Mistura Cretæ*.) Lozenges of chalk were also official under the name of *Trochisci Cretæ* in the *U. S. P.* 1890. Prepared chalk is better fitted for chalk mixture than the precipitated calcium carbonate, in consequence of its more impalpable character and greater powers of adhesion.

Dose, from ten to forty grains (0.65 to 2.6 Gm.).

CROCUS. Br.

SAFFRON

(cro'cūs)

"The dried stigmas and tops of the styles of *Crocus sativus*, *Linn.*" *Br.*

Stigmata Croci, Spanish Saffron; Safran, *Fr. Cod.*; Crocus, *P. G.*; Safran, *G.*; Zafferano, *It.*; Azafran, *Sp.*

Crocus sativus, Willd., *Sp. Plant.* i. 194; Woodv., *Med. Bot.*, p. 763, t. 259.—The common cultivated saffron is a perennial plant, with a rounded and depressed bulb or corm, from which the flower rises a little above the ground,

upon a long, slender, white, and succulent tube. The flower is large, of a beautiful lilac or bluish-purple color, and appears in September or October. The leaves are radical, linear, slightly revolute, dark green upon their upper surface, with a white longitudinal furrow in the centre, paler underneath, with a prominent flattened midrib, and enclosed at their base, together with the tube of the corolla, in a membranous sheath, from which they emerge soon after the appearance of the flower. The style hangs out on one side between the two segments of the corolla, and terminates in three long convoluted stigmas, which are of a rich orange color, highly odorous, rolled in at the edges, and notched at the summit. The stigmas of the *Crocus orientalis* are used in the East.

C. sativus, or *autumnal crocus*, is believed to be a native of Greece and Asia Minor, where it has been cultivated from the earliest ages. There are three main varieties of it, the French, the Grecian, and the Chinese. The first of these is superior in color and flavor, the second in the amount of yield, while the third is said to unite these qualities. Saffron is also cultivated for medicinal use in Sicily, Spain, France, England, and other temperate countries of Europe. Large quantities of saffron are raised in Egypt, Persia, and Cashmere, whence it is sent to India. Much of the drug reaches the market of Constantinople from the neighborhood of Tiflis and the Caucasus. We cultivate the plant in this country chiefly as a garden flower, although some of the drug of very fine quality has been produced in Pennsylvania; the high cost of labor in America will probably prevent the possibility of its coming into commerce. It is liable to two diseases, which interfere with its culture,—one dependent on a parasitic fungus which attaches itself to the bulb, the other called by the cultivators in France *tacon*, by which the bulb is converted into a blackish powder. (*J. P. C.*, xviii. 41.) Wild saffron is found growing in uncultivated fields in Southern Russia; Tichomirow believes that these are varieties of *C. sativus* and *C. speciosus*, Marsh. Biebr., var. *β-Pallassii* (*C. Pallassii*, Marsh. Biebr.). He further states that wild saffron from these sources is in no way inferior to that which is official. (*A. Pharm.*, 1903, 656.)

In England the flowers appear in October, and the leaves continue green through the winter; but the plant does not ripen its seed, and is propagated by offsets from the bulb. These are planted in grounds prepared for the purpose, and are arranged either in rows or in small patches at certain distances. The flowers are gathered soon after they show themselves, as the period of flowering is very short. The stigmas, or summits of the pistils, together with a portion of the style, are separated from the remainder of the flower, and carefully dried by artificial heat, or in the sun. During this process they are sometimes made to assume

¹ "Take of Chalk a convenient quantity. Add a little water to the Chalk, and rub it into fine powder. Throw this into a large vessel nearly full of water, stir briskly, and, after a short interval, decant the supernatant liquor, while yet turbid, into another vessel. Treat the coarser particles of the Chalk, remaining in the first vessel, in a similar manner, and add the turbid liquid to that previously decanted. Lastly, set the liquor by, that the powder may subside, and having poured off the water, dry the powder." *U. S.* 1870.

the form of a cake by pressure; but the finest saffron is that which has been dried loosely. The two forms are distinguished by the names of *cake saffron* and *hay saffron*. Five pounds of the fresh stigmas are said to yield one pound of the dried. The English saffron, formerly most highly esteemed in this country, has disappeared from our market. What may be sold under the name is probably derived from other sources. Much of the drug is imported from Gibraltar, packed in canisters. Parcels of it are also brought from Trieste and other ports of the Mediterranean. The Spanish saffron is generally considered the best in the United States, although most European writers on *Materia Medica* give the preference to the French saffron. Genuine *cake saffron* is at present seldom found in commerce. The better grades of Spanish saffron are known as *Valencia saffron*, while *Alicante saffron* is said by Maisch to contain scarcely more than 50 per cent. of genuine saffron. According to Landerer, the stigmas of several other species besides those of *C. sativus* are gathered and sold as saffron in Greece and Turkey.¹

Properties.—Saffron has a peculiar, sweetish, aromatic odor, a warm, pungent, bitter taste, and a rich deep orange color, which it imparts

to the saliva when chewed. The stigmas of which it consists are an inch or more in length, expanded and notched at the upper extremity, and narrowing towards the lower, where they terminate in a slender, capillary, yellowish portion, forming a part of the style. They were officially described in the U. S. P. 1890 as "separate stigmas, or three, attached to the top of the style, about 3 Cm. long, flattish-tubular, almost thread-like, broader and notched above; orange-brown; odor strong, peculiar, aromatic; taste bitterish and aromatic. Saffron should not include the yellow styles. When pressed between filtering paper, it should not leave an oily stain. When chewed it tinges the saliva deep orange-yellow. When soaked in water, it should not deposit any pulverulent, mineral matter, nor show the presence of organic substances differing in shape from that described. On agitating 1 part of Saffron with 100,000 parts of water, the liquid will acquire a distinctly yellow color. No color is imparted to benzin agitated with saffron (absence of *picric acid* and some *other coal-tar colors*). On drying Saffron at 100° C. (212° F.), it should not lose more than 14 per cent. of its weight (absence of *added water*). When thus dried, and ignited with free access of air, 100 parts of the dry Saffron should not leave more than 7.5 per cent. of ash (absence of *foreign inorganic substances*)."
U. S. 1890. "Incinerated with free access of air, dried Saffron does not deflagrate (absence of nitrates), and yields about 7 per cent. of ash. It should not lose more than 12.5 per cent. of moisture when dried at 212° F. (100° C.)."
Br. Analyzed by Vogel and Bouillon-Lagrange, saffron afforded 65 per cent. of a peculiar extractive matter, and 7.5 of an odorous volatile oil, together with wax, gum, albumen, saline matter, water, and lignin. The extractive was named *polychroïte*, from the changes of color which it undergoes by the action of reagents. Weiss (Wiggers and Husemann, *Jahresbericht*, 1868, 35) considered *polychroïte* to be a glucoside, but later researches have shown that it is a mixture of the glucoside crocin, sugar, and essential oil. (Planchon, *Drogues Simples*, vol. i. 210.) Kayser obtained (*Ber. d. Chem. Ges.*, 1884, 2228) pure *crocin*, having the formula $C_{41}H_{70}O_{23}$, as a yellow powder, easily soluble in water and diluted alcohol, slightly soluble only in absolute alcohol, and giving with concentrated sulphuric acid a deep blue color, which turns violet, then cherry-red, and finally brown. It is easily decomposed by lime or baryta water into *crocin* and a right-rotating sugar which Kayser calls *croscose*. The *crocin* is a red powder, not soluble in water, but easily soluble in alcohol and ether. Its solution in alkalies shows an orange-yellow color, from which solution acids separate it again in orange-colored flocks. Its formula is $C_{54}H_{46}O_9$, or according to Schmuck and Marchlewski, $C_{15}H_{20}O_4$. Kayser also found a colorless bitter principle, to which he gave the name *picro-crocin* or *saffron bitter*, and the

¹ At the International Exhibition in London in the year 1862, Geo. B. Wood noticed a specimen of saffron from the island of Ceylon, closely resembling that from *Crocus sativus*. It consisted of the stigmas of the *Crocus orientalis*. According to Charles A. Heinitsh, saffron was formerly cultivated to a considerable extent in Lancaster County, Pa. The plant requires a rich soil, which should be deeply dug and heavily manured. The bulbs are planted in August, eight inches apart, and the growing plant should be kept free from weeds. The flowering period begins about the middle of September, and continues until the beginning of October. The flowers are picked early in the morning, and the stigmas separated and dried in the shade. This is done every day during the period of flowering. A plot of 72 square feet will produce 9000 stigmas, weighing 420 grains, or from 33 to 36 pounds to the acre. (*A. J. P.*, 1867, p. 38.) In the Apennines the bulbs, which have been left in the ground during the winter without protection, are removed in August, are planted again in September in rows, and four weeks later the collection of the flowers is begun. (See *A. Pharm.*, Aug. 1885.) For an account of the cultivation in England, see *P. J.*, June, 1887. Monthus, an experienced cultivator in France, prefers a dry calcareous soil; plants the bulbs 3 or 4 inches deep; after the harvest in October manures the ground; and renews the planting every three years. He thus prevents the diseases peculiar to the plant. Monthus recommends the *petals* of the flower as applicable to the same purposes as the stigmas, having found them to be possessed of aromatic properties. They demand no peculiar caution in drying; but to preserve them it is necessary to exclude light and moisture. Acids redden them with extreme facility, and alkalies turn them green. He therefore recommends a tincture to be made from them, as a substitute for syrup of violets. He prepares the tincture by macerating 10 parts of the dried flowers in 100 parts of alcohol of 40°, for 48 hours. A longer maceration would destroy the color. Paper may be stained with the tincture, and kept green or red, the former for acids, the latter for alkalies. (*J. P. C.*, Juillet, 1867, 54.) According to Heim, *Crocus aurea*, Pl., which is cultivated in Southern Africa as a dye-stuff, affords an excellent substitute for saffron, the dried petals giving, when treated with water, a brilliant yellow solution. The yellow coloring matter is more soluble in diluted alcohol and in alkaline solutions than in water, but is insoluble in absolute alcohol and in benzene. The partly dry aqueous extract gives with sulphuric acid a blue coloration, passing to violet, similar to that obtained from saffron.

formula $C_{25}H_{35}O_{17}$, which is also of glucoside character. It is to the essential oil, which, according to Henry, is present to the amount of 10 per cent., that saffron owes its activity. It may be partially separated by distillation. It has the formula $C_{10}H_{14}O$, boils at 208° to 210° C. (406.4° to 410° F.), is yellow, of a hot, acrid, bitterish taste, and heavier than water, in which it is slightly soluble.

Adulterations.—The high price of this medicine gives rise to frequent adulterations. Water is said to be very often added in order to increase its weight. Oil or glycerin is also added for the same purpose, or to improve the appearance. In some specimens the dyed corolla of the crocus with the attached stamens is abundant. Sometimes the flowers of other plants, particularly *Carthamus tinctorius*, or safflower, *Calendula officinalis*, or official marigold, and *arnica*, are fraudulently mixed with the genuine stigmas. They may be known by their shape, which is rendered obvious by throwing a portion of the suspected mass into hot water, to expand them. (See *Carthamus*, PART II.) A specimen of this adulteration has been introduced into the American market, by the name of *African Saffron*. (Maisch, A. J. P., March, 1872, p. 110.) Other adulterations are the fibres of dried beef, the stamens of the crocus, distinguishable by their yellow color, the stigmas previously exhausted in the preparation of the infusion or tincture, and various mineral substances, easily detected upon close examination. The flowers of a Brazilian plant named *Fuminella* have, according to M. J. L. Soubeiran, been employed for the adulteration of saffron. They may be detected by shaking, gently but repeatedly, a large pinch of the suspected saffron over a piece of paper. The flowers of *Fuminella*, being smaller and heavier, separate and fall, and may be seen to consist of very short fragments, with a color like that of saffron, but a rusty tint which the latter does not possess. (See *Ph. Rev.*, 1898, 258.) J. Müller recommends concentrated sulphuric acid as the most certain test of saffron. It instantly changes the color of pure saffron to indigo blue. (*Chem. Gaz.*, May, 1845.) An adulteration which has been largely practised appears to consist of yellow-colored chalk or barium sulphate, made into a thin paste, probably with honey, and attached to the stigmas, sometimes isolated, sometimes in groups of five or six, enveloping them almost completely. If this saffron be kept in a dry place, and often handled, the paste becomes partly broken up, and the colored powder spreads itself in the mass and the envelope. The chalk can at once be detected by shaking the suspected saffron with water, and treating the precipitated powder with hydrochloric acid, when effervescence will occur. A less than the ordinary brightness of color in the saffron should lead to suspicion of this adulteration. Much can be told as to the purity of saffron by agitating the suspected flowers in distilled water; if the

drug be pure the liquid will remain clear, slowly assuming a fine pure yellow tint; the saffron also will retain its red color for hours. Another excellent plan is to scatter a pinch of the flowers upon the surface of warm water, when the stigmas should spread out and display their proper form. Minute fragments of red saunders, which are often added to saffron, may be separated by agitating with water. For an elaborate discussion of adulteration, see A. J. P., 1885, 487.¹ Adulterations of crocus may sometimes be detected by remembering that the pollen grains should be covered with very numerous fine prickles and should have a diameter of close to 98.175 mikrons. In various European markets there has been offered a saffron largely adulterated with borates, chlorides, and other salts of sodium and potassium, and yet retaining the physical properties of saffron of high character. These and other adulterations with inorganic salts can be detected by the amount of ash left on burning, genuine saffron leaving from five to seven per cent. This saffron also yielded immediately to water an orange-yellow color. Further, some of it at least was hygroscopic, so that when rubbed up between the fingers into a ball it retained that form instead of being elastic as is true saffron.

Attention has been called to a product of the Cape of Good Hope, named *Cape saffron*, which has a remarkable resemblance to genuine saffron, having a similar odor, and yielding a similar color to water, though the flowers themselves are differently colored. It is the flower of a small plant very abundant at the Cape, belonging to the family of *Scrophulariaceæ*, and

¹ B. S. Procter has proposed a seemingly efficient color test. One grain of saffron is to be agitated with two drachms of ether, which should become fairly yellow (any over-coloring of the ether indicates aniline or other dye); ether decanted; saffron dried, then agitated with two drachms of rectified spirit, and heated short of ebullition, for about one hour; next dried with two drachms of water in the same manner; this alternate use of spirit and water is to be continued until the solvent ceases to extract color and the fibres are nearly white; the total liquids being made up to exactly two fluidounces should have a color closely resembling that of fourteen grains of potassium dichromate in two ounces of water. In comparison, the best results are obtained by taking eight minims of the standard liquid and diluting it with an ounce of water, half filling a test tube about half an inch in diameter with this diluted standard, then adding to an ounce of water eight minims of the liquid obtained from the sample under examination, and having half filled a similar test tube with this, holding the two tubes side by side against a sheet of white paper. E. Vinassa recommends that saffron should always be steeped in petroleum before examination under the microscope, and the particles should then all present equality in coloration. Immersion in hydrated chloral and subsequent boiling with water enable the operator easily to detect admixtures of sandal or campeche wood and of safflower. Attention should also be paid to the pollen grains, hairs, and crystals present. Chemical examination shows that the amount of water should not exceed 16 per cent. and the ash 8 per cent. In a good sample, while the tinctorial power may be estimated by comparison with potassium dichromate solution. The capillary behavior of an aqueous solution of saffron is characteristic in that distinct zones of color are produced in strips of filtering paper dipped in the solution, the uppermost zone being terminated by a sharply defined light yellow line. (*Bull. Pharm.*, Nov. 1892.)

is said by Pappé of Cape Town, to possess medicinal virtues closely resembling those of true saffron. The flowers have been used successfully in the convulsions of children. (*P. J.*, vi. 462, 1865.)

Choice of Saffron.—Saffron should not be very moist, nor very dry, nor easily pulverized; nor should it emit an offensive odor when thrown upon live coals. The freshest is the best, and that which is less than a year old should, if possible, be selected. It should possess in a high degree the characteristic properties of color, taste, and odor. When agitated with water it should color it bright yellow, and it should not effervesce in the presence of a diluted acid. If it does not color the fingers when rubbed between them, or if it has an oily feel, or a musty flavor, or a black, yellow, or whitish color, it should be rejected. In the purchase of this drug in cakes, those should be selected which are close, tough, and firm in tearing; and care should be taken to avoid *cakes of safflower*.

As its activity depends, partly at least, on a volatile ingredient, saffron should be kept in well-stoppered vessels. Some recommend that it should be enclosed in a bladder and introduced into a tin case.

Uses.—Saffron was extensively used by the ancients and by mediæval physicians, as a highly stimulant antispasmodic and even narcotic emmenagogue, and is still employed to some extent upon the Continent; but in Great Britain and the United States it has fallen into well deserved and almost complete disuse. In domestic practice saffron tea is occasionally used in *exanthematous diseases*, to promote the eruption. At present it is chiefly used to impart color and flavor.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

CUBEBA. U. S. (Br.)

CUBEB

(cû-bé'ba)

"The dried unripe, but fully grown fruit of *Piper Cubeba* Linné filius (Fam. *Piperaceæ*)." *U. S.* "The dried full-grown unripe fruits of *Piper Cubeba*, Linn. fil." *Br.*¹

Cubebæ Fructus, *Br.*; Fructus (s. Baccæ) *Cubebæ*, *Piper* Caudatum; Cubebæ, Tailed Pepper; Cubèbe, Cubèbe ou Poivre à Queue, *Fr. Cod.*; Cubebæ, *P. G.*; Kubeben, *G.*; Pepe Cubebe, *Cubebe, It.*; Cubeba, *Sp.*; Kebabeh, *Ar.*

¹ The fruit of the *Piper Afzeli* of Lindley, *Cubeba Clusi* of Miquel, figured in the *P. J.* (xiv. 201), is known in commerce as *African cubeba*, *Ashantee pepper*, *Guinea pepper*, or *African black pepper*. It was formerly taken to Europe in considerable quantities by the Portuguese, but has been superseded by the more agreeable products of the East Indies. The fruit is one-third smaller than the official cubeb, is more compact, and has a taste more analogous to that of ordinary black pepper. Stenhouse has also shown that it is chemically more analogous to black pepper than

Piper Cubeba, Willd., *Sp. Plant.* i. 159; Woodv., *Med. Bot.*, 3d ed., v. 95.—*Cubeba officinalis*, Miquel.—This is a climbing perennial

to cubeb, as it contains piperin and not cubelin. (*Ibid.*, xiv. 364.) An alleged *African cubeba* which has been sent to London from Cape Coast Castle, in Africa, is the fruit of a plant belonging to the *Xanthoxylaceæ*, probably either a *Toddalia* or a *Vepris*. According to Archer, it is simply aromatic and stimulant, without any of the special virtues of cubeb. (*P. J.*, March, 1865, 463.)

Our knowledge of the false cubeb of commerce up to 1894 was epitomized in the 17th edition of the *U. S. D.*, p. 457. To this account the reader is referred for historical details. In 1894 the subject was much clarified by A. De Wevre, a long abstract of whose memoir may be found in the *P. J.*, xxv. 1894. It appears that the natives of Java recognize three varieties of the cubeb plant under the respective names of *Rinoe kateentjar*, *Rinoe badak*, and *Rinoe tjaroelock*. Of these the first is true cubeb. *Rinoe badak* yields a fruit strongly resembling the genuine cubeb, but having from eight to nine or even twelve rows of cells in the mesocarp, and yielding, when crushed with sulphuric acid, a yellow-brown or orange tone instead of the carmine-red color given by the true cubeb.

Rinoe tjaroelock is believed by De Wevre to be the *Piper crassipes* of Kirkby, and to be simply a variety of *Piper Cubeba*, so that its fruit must be considered to be a true cubeb, though it differs from the official drug in having its pedicel about twice as long as the fruit and flattened throughout, and in having an odor of mace and a more bitter and less burning taste than true cubeb, and yielding, when crushed with sulphuric acid, a brown color only. Its mesocarpic cells are in six or seven rows.

The large false cubeb of English commerce, commonly believed to be yielded by *Piper crassipes* of Korth, is a large, globular, brown or blackish fruit borne on a curved pedicel, usually at least twice as long as the fruit; the pedicel is not flattened, and is sometimes tapering, but never dilated, at its free extremity. The fruit measures from 7 to 8.5 Mm., and the pedicel 12 to 23 Mm. The taste is bitter, but does not leave a persistent burning sensation in the mouth. Sulphuric acid gives with the crushed fruit a yellow coloration. So far as De Wevre's examination went, *Piper crassipes* of Korth is identical with *Piper ribesoides*, Wallich.

A short pedicelled cubeb which occurs in commerce, in which the feebly aromatic fruit is from 4 to 5 Mm. in diameter and the pedicel 1 Mm., is especially characterized by a layer of small cells under the epidermis, like those of the epidermis, by a hypodermal layer of three or four rows of polygonal uniform stone cells, and by the cubical cells of the endocarp being cutinized in horseshoe fashion,—that is, having the outside wall thinner than the other three (the reverse of what occurs in black pepper).

Kebœ cubeb is much larger than the official, being about 7 Mm. in diameter, with a pedicel 16 Mm. long; the color is blackish or grayish black, the surface much wrinkled, the taste acrid, slightly bitter, and pungent, and the strong odor differently from that of cubeb. It is said to be yielded by *Piper (Pothomorphe) mollissimum*, Bl., and the *P. crassipes* of Brunotte.

The fruit of the *Daphnidium Cubeba*, a rather common adulteration of cubeb, has been shown to be identical with that of *Tetranthera citrata*. It is especially characterized by its endocarp, which consists of long, narrow, sclerenchymatous cells, crowded closely together in a single line and arranged radially. The taste of the fruit is slightly bitter and aromatic, but not burning. It has usually no pedicel, and the pericarp contains a plainly dicotyledonous seed without albumen, whereas in the cubeb the embryo is too small for the naked eye to distinguish the cotyledons, the mass of the seed consisting of albumen. The cells of the endocarp have a very narrow linear cavity, and are very distinct from those of cubeb. Even the powder of *Daphnidium Cubeba* is to be recognized from that of a *Piper* by the absence of small angular starch granules.

Among the other species of *Piper* whose berries have been found in cubeb,—in the African *P. Clusi*, D. C., and *P. guineense*, Schum., and in the Japanese *P. Lowong*, Bl., and *P. schvestre*, Lam.,—neither the endocarp nor the hypoderm contains sclerenchymatous cells; while in *P. mollissimum*, Bl., the endocarp is not sclerenchymatous and the hypoderm very sparingly so. De Wevre refers to a species of *Rhamnus*, certain adulterating berries which occur in the cubeb. These berries are nearly tasteless, with an

plant, with a smooth, flexuous, jointed stem, and entire, petiolate, oblong or ovate-oblong, acuminate leaves, rounded or obliquely cordate at the base, strongly nerved, coriaceous, and very smooth. The flowers are dioecious and in spikes, with peduncles about as long as the petioles. The fruit is a globose, pedicelled berry. This species of *Piper* is a native of Java, Penang, and probably other parts of the East Indies. It is extensively grown in the coffee plantations, supported by the trees which are used for shade, and has been introduced into Ceylon. The dried unripe fruit is the official portion.

Properties.—Cubeb is round, about the size of a small pea, of a blackish or grayish-brown color, and furnished with a short stalk, which is continuous with raised veins that run over the surface of the berry and embrace it like a network. The shell is hard, almost ligneous, and contains within it a single loose seed, covered with a blackish coat, and internally white and oleaginous. "From 10 to 13 Mm. long, the upper portion globoidal, 4 to 5 Mm. in diameter, contracted at the base into a slender stem-like portion, about 6 or 8 Mm. long, pericarp reticulately wrinkled, blackish-gray, about 0.3 Mm. thick; internally light brown, smooth, oily, one-seeded; brittle; of a strongly aromatic, somewhat camphoraceous odor and taste. The powder contains few or no starch grains, and on treatment with sulphuric acid the fragments become wine-colored." *U. S.* "A transverse section of the pericarp exhibits two layers of sclerenchymatous cells, one near the outer, the other near the inner surface, those of the latter being radially elongated. The crushed fruit imparts a crimson color to sulphuric acid." *Br.*

odor somewhat resembling that of *Daphnidium Cubeba*, are rounded and compressed laterally, with two rather deep furrows, separating the fruit into halves, and have, internally, two cells. Their powder is characterized by the presence of a great number of stone cells, entirely different in form from those of cubebes.

E. M. Holmes and E. D. Gravill (*P. J.*, vol. xv.) give the following tests which may be available in detecting powdered false cubeb. After being crushed, the genuine cubeb gives on a porcelain slab with concentrated sulphuric acid a deep crimson with a distinct carmine tint in it. *P. crassipes* strikes a reddish-brown color, *Daphnidium Cubeba* a yellowish brown color. Iodine gives with a decoction of genuine cubeb a pure blue tint, and with spurious cubeb a dull purple tint. One cubic centimeter of the tincture of true cubeb treated with ten cubic centimeters of strong sulphuric acid (sp. gr. 1.843) develops a deep violet color, the false cubeb similarly treated a deep red-brown. On diluting these mixtures with four fluidounces of distilled water and allowing them to stand, the true cubeb becomes opalescent and changes to a deep blue; that made from the false becomes opalescent and changes to a dirty yellow. In applying these tests to adulterated cubeb, the color developed will, of course, be dependent upon the amount and character of the adulteration. An important conclusion reached by De Wevre is, that it is not possible to detect by microscopic examination with certainty the freedom of a powdered cubeb from adulteration with various berries, especially those yielded by different species of the genus *Piper*, although the presence of numerous polygonal stone cells would indicate adulteration, while the peculiar prismatic sclerenchymatous cells of the true cubeb indicate genuineness. It would seem to be essential for the pharmacist to buy his cubeb whole, and examine the fruit before powdering.

The odor of the berry is agreeably aromatic; the taste warm, bitterish, and camphorous, leaving in the mouth a peculiar sensation of coolness, like that produced by oil of peppermint. The pericarp of the cubeb berry consists of three layers, the exterior of which is composed of an interrupted row of small, thick-walled cubical sclerenchymatous cells arranged in irregular groups of three or four. The middle layer of the pericarp is composed of loose, undeveloped tissue, interspersed with large oil cells, and contains quantities of starch and sometimes groups of needle-shaped crystals. The inner layer is free from starch, and is formed of four rows of parenchymatous cells. At the junction of the inner and middle layers there are usually from ten to twelve distinct woody bundles, chiefly composed of narrow spiral vessels along with a few dotted vessels. The mesocarp is composed of compressed parenchymatous cells, of which there are usually four rows, while the endocarp is formed of long sclerenchymatous cells arranged radially,—i.e., on their ends. The testa consists of one row of large, thick-walled cells. The perisperm is surrounded by red membrane, formed of rather large cells, and is composed of angular parenchymatous cells containing starch and oil. On allowing thin sections to stand in glycerin for a few weeks, crystals are formed both in the pericarp and in the perisperm. The chief characteristics of the powder are described as being a dark-colored and oily aspect, and it is microscopically characterized by the presence of prismatic sclerenchymatous cells.

The most obvious constituent of cubeb is the volatile oil, the proportion of which yielded by the drug varies from 4 to 13 per cent. It is, as shown by Ogialoro, a mixture of an oil, $C_{10}H_{16}$, boiling at 158° to 163° C. (316.4° to 325.4° F.), which is present in very small amount, and is probably pinene or camphene, some dipentene, and two oils of the formula $C_{15}H_{24}$, boiling at 262° to 265° C. (503.6° to 509° F.). One of these, known as *cadinene*, is strongly levogyrate, and yields a crystallized compound having the formula, $C_{15}H_{22}2HCl$, and melting at 118° C., while the other is less levogyrate, and does not combine with HCl.

The oil distilled from old cubeb on cooling at length deposits large transparent inodorous octahedra of *camphor of cubeb*, $C_{15}H_{22}O$. E. Schmidt found that this camphor melts at 66.5° C.; simply by standing over sulphuric acid, more rapidly on heating, it gave up water and passed into that fraction of cubeb oil which boils at 260° C., of which it is, therefore, simply the hydroxide. Another constituent of cubeb is *cubebin*. This is an inodorous substance, crystallizing in small needles or scales, melting at 125° C. (257° F.), having a bitter taste in alcoholic solution; it dissolves freely in boiling alcohol, but deposits on cooling, and is abundantly soluble in chloro-

form. Its composition, according to Weidel (1877), is $C_{10}H_{10}O_3$, and its structural formula,

sium hydroxide it yields proto-catechuic acid. The resin extracted from cubeb consists of an indifferent portion, nearly 3 per cent., and of *cubebic acid*, $C_{13}H_{14}O_7$, amounting to about 1 per cent. (*Pharmacographia*, 2d ed., p. 587.)

The formula of cubebic acid as just given is that of Schmidt. Schultze (*Jahresbericht*, 1873, p. 863), on the other hand, gives to it the formula $C_{22}H_{30}O_7 + H_2O$. According to Capitaine and Soubeiran, *cubebin* is best obtained by expressing cubeb from which the oil has been distilled, preparing from the mere an alcoholic extract, treating this with a solution of potassium hydroxide, washing the residue with water, and purifying it by repeated crystallizations in alcohol. In the official oleoresin of cubeb a deposit takes place consisting chiefly of cubebin, which may be obtained by washing the deposit with a small quantity of cold alcohol to remove adhering resin and oil, and then dissolving repeatedly in boiling alcohol, and crystallizing until the product is white.¹ The volatile oil is official. (See *Oleum Cubebæ*.) By practical trial Bernatzik has satisfied himself that the peculiar virtues of cubeb as a remedy in gonorrhœa depend not on the cubebin or the volatile oil, but on the cubebic acid. When the ethereal extract of cubeb is deprived of its volatile oil by evaporation on a water bath, and of cubebin and wax by deposition, a soft resin is left, the *cubebic acid* of Bernatzik, in which, according to F. V. Heydenreich, who experimented with it as a physiological agent, the diuretic properties reside, the cubebin being without apparent effect, and the volatile oil, though stimulant and carminative, having no diuretic action. The soft resin, which was of the consistence of honey, of a dark olive-green color, and some remaining odor of cubeb, when taken in the dose of ten grains every two hours for six hours, acted as a laxative, and gave the urine a peculiar odor, without increasing its quantity; but in the dose of a drachm, once repeated at an interval of three hours, while it produced the same effects as the smaller dose, it considerably augmented the urine. In still larger doses it produced decided irritation of the urinary passages. (*A. J. P.*, Jan. 1868.) Heydenreich's experiments are confirmatory of Bernatzik's conclusion as to the peculiar active principles of cubeb. Cubeb gradually deteriorates by age, and in powder becomes rapidly weaker, in con-

sequence of the escape of its volatile oil. It should be kept whole, and pulverized when dispensed. The powder is said to be sometimes adulterated with that of pimenta.

Uses.—Cubeb is generally stimulant, with a special direction to the urinary organs. In considerable quantities it excites the circulation, increases the heat of the body, and sometimes occasions headache and giddiness. At the same time it frequently produces an augmented flow of the urine, to which it imparts a peculiar odor. Among its effects are also occasionally nausea and moderate purging, and it is said to cause a sense of coolness in the rectum during the passage of the fæces. We have no evidence that it was known to the ancients. It was probably first brought into Europe by the Arabians, and was formerly employed for similar purposes as black pepper, but it was found much less powerful and fell into disuse. In India it has long been used in *gonorrhœa* and *gleet*, and as a grateful stomachic and carminative in disorders of the digestive organs, and it is at present very frequently given both in this country and in Europe in *gonorrhœa*, after the subsidence of the first active inflammatory symptoms. It has been given also in *leucorrhœa*, *cystorrhœa*, the *urethritis* of women and female children, *abscess of the prostate gland*, *piles*, and *chronic bronchial inflammation*. In connection with copaiba it has been especially recommended in affections of the neck of the bladder and the prostatic portion of the urethra. It is best administered in powder, of which the dose in gonorrhœa is from one to three drachms (3.9 to 11.6 Gm.) three or four times a day. The volatile oil may be substituted, in the dose of ten or twelve minims (0.6 to 0.7 Cc.), suspended in water by means of sugar, though, if the experiments of Bernatzik and Heydenreich are to be relied on, the oil is much less efficient than the soft resin as a remedy in gonorrhœa and in diseases of the urinary passages generally. An alcoholic extract is directed by the U. S. P., and is much used, and, as it contains soft resin or cubebic acid, it is no doubt very efficient. (See *Oleoresina Cubebæ*.) An infusion, made in the proportion of an ounce of cubeb to a pint of water, has been employed as an injection in discharges from the vagina.

Dose, of powdered cubeb, ten grains to one drachm (0.65 to 3.9 Gm.).

CUPRI SULPHAS. U. S., Br.

COPPER SULPHATE [Cupric Sulphate]

(cū'prī sūl'phās)

"It should contain not less than 99.5 per cent. of pure Copper Sulphate [$SO_4.O_2Cu +$

¹ E. Schaer calls attention to the similarity in reaction between cubebin and veratrine, acetonine, morphine, and digitalin. (*A. Pharm.*, 1887, p. 531.)

5H₂O].” U. S. “This salt, CuSO₄·5H₂O, may be obtained by the interaction of water, sulphuric acid, and copper or cupric oxide.” Br.

Cuprum Vitriolatum; Blue Vitriol, Roman Vitriol, Blue Stone; Sulfate de Cuivre, Fr. Cod.; Vitriol bleu, Couperose bleu, Fr.; Cuprum Sulfuricum, P. G.; Schwefelsaures Kupfer, Kupfersulfat, Kupfervitriol, Blauervitriol, Blauer Galltzenstein, G.; Solfato di rame, Vitriolo di rame, It.; Sulfato cuprico, Vitriolo azul, Sp.

Preparation.—Copper sulphate occasionally exists in nature, in solution in the water which flows through copper mines. In this case the salt is procured by merely evaporating the waters which naturally contain it. Another method of obtaining it is to roast the native sulphide in a reverberatory furnace, whereby it is made to pass, by absorbing oxygen, into the state of sulphate. The roasted mass is lixiviated, and the solution obtained evaporated that crystals may form. The salt procured by either of these methods contains a little ferric sulphate, from which it may be freed by adding either an excess of cuprous oxide, which precipitates ferric oxide, or recently precipitated copper subcarbonate, which causes the deposition of the iron as a carbonate. (A. J. P., xxxiv. 507.) A third method is to dissolve copper scales to saturation in sulphuric acid contained in a wooden vessel lined with sheet lead. The scales consist of metallic copper mixed with oxide, and are produced in the process for annealing sheet copper.

Most of the copper sulphate produced at present is obtained as a by-product by the gold, silver, and copper refiners. The production of copper sulphate in the United States is very large. In 1901 the exportations of sulphate amounted to 49,223,183 lbs., valued at \$2,324,738, and in 1904 to 26,077,087 lbs., valued at \$1,133,686.

In the U. S. Pharmacopœia copper sulphate is presumed to be obtained pure from the manufacturer; the British Pharmacopœia suggests the method in which it may be prepared, without entering into the details of the process. The German Pharmacopœia has two kinds official, *Cuprum sulfuricum*, which corresponds with the former *Cuprum sulfuricum purum*, and *Cuprum sulfuricum crudum*, or commercial sulphate.

Properties.—Copper sulphate has a rich deep blue color, and a strong metallic, styptic taste. It reddens vegetable blue, and crystallizes in “large, transparent, deep blue, triclinic crystals; odorless; of a nauseous, metallic taste; slowly efflorescent in dry air. Soluble in about 2.2 parts of water, 400 parts of alcohol, and 3.5 parts of glycerin at 25° C. (77° F.), and in 0.5 part of boiling water. When heated to 30° C. (86° F.), the salt loses 2 of its 5 molecules of water (14.43 percent.), and is converted into a pale blue amorphous powder. Two more molecules of water are lost at 100° C. (212° F.), while the fifth is retained until 200° C. (392° F.) is reached, when a

white, anhydrous powder remains (63.9 percent. of the original weight). At a still higher temperature, sulphur dioxide and oxygen are given off, and a residue of black cupric oxide is left. The aqueous solution (1 in 20) has a blue color, and shows an acid reaction with blue litmus paper. If a drop of the solution be placed upon a bright piece of iron, a red film of metallic copper will be produced. With potassium ferrocyanide T.S. the solution yields a deep reddish-brown precipitate. Barium chloride T.S. produces in the solution a white precipitate, insoluble in hydrochloric acid. If ammonia water be added to the solution, drop by drop, a pale blue precipitate of cupric hydroxide is formed, which redissolves in an excess of ammonia water, forming a deep azure-blue solution. If hydrogen sulphide gas be passed through 10 Cc. of the aqueous solution of the salt (1 in 20), to which 1 Cc. of diluted hydrochloric acid has been added, until all of the copper is precipitated as sulphide, one-half of the colorless filtrate should not be colored or rendered turbid upon the addition of ammonia water, nor should the remaining portion of the filtrate yield, upon evaporation, a weighable residue (limit of iron, aluminum, etc.). If the aqueous solution of the salt (1 in 20) be heated to boiling with an excess of sodium hydroxide T.S., until all of the copper has been converted into black cupric oxide, it will yield a colorless filtrate, which, after acidulation with acetic acid, should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121).” U. S. “Soluble in 3.5 parts of cold water, forming a solution which strongly reddens litmus; very soluble also in glycerin, almost insoluble in alcohol (90 per cent.). It affords the reactions of copper and of sulphates. It should yield no characteristic reaction with the tests for lead, arsenium, zinc, or aluminium, and not more than the slightest reactions with the tests for iron.” Br. When heated, copper sulphate first melts in its water of crystallization, and then dries and becomes white. If the heat is increased, it next undergoes the igneous fusion, and finally, at a high temperature, loses its acid, cupric oxide being left. Four of the molecules of water of crystallization can be driven off at 100° C. (212° F.); but the fifth goes off only at a temperature of from 220° C. (428° F.) to 240° C. (464° F.), when the anhydrous salt remains. Potassium hydroxide, sodium hydroxide, and ammonia throw down from it a bluish-white precipitate of hydrated cupric oxide, which is immediately dissolved by an excess of the last mentioned alkali, forming a rich deep blue solution, called *aqua sappharina*. It is decomposed by the alkaline carbonates, and by borax, lead acetate and subacetate, ferric acetate, silver nitrate, mercuric chloride, potassium tartrate, and calcium chloride, and it is precipitated by all astringent vegetable infusions. If it becomes very green on the surface by the action of

the air, it contains ferric oxide. This oxide may also be detected by ammonia, which will throw it down along with the copper oxide, without taking it up when added in excess. When copper sulphate is obtained from the *dipping liquid* of manufacturers of brass or German silver ware, it is always contaminated with zinc sulphate, as pointed out by S. Piesse. This liquid is at first a mixture of sulphuric and nitric acids, but becomes, at last, nearly saturated with copper. When zinc is present in copper sulphate, it will be taken up by solution of potassium hydroxide added in excess, from which it may be thrown down, after filtration, in white flocks, by a solution of bicarbonated alkali.

Uses.—Copper sulphate is irritant or mildly escharotic, and when in diluted solution, stimulant and astringent. At one time it was given in *epilepsy* and other nervous diseases, but at present it is never used internally, except for its influence upon the gastro-intestinal mucous membrane. In *chronic diarrhœa* with ulceration it is often a useful remedy. In doses of 5 grains it acts as a powerful, prompt emetic, without causing general depression or much nausea, but is too irritant to be used freely. Externally it is employed in solution as a stimulant to ill-conditioned *ulcers*, as an escharotic for destroying *warts*, fungous *granulations*, and callous edges, and as a styptic to bleeding surfaces. It is found, in not a few instances, to promote the cicatrization of ulcers, and is not infrequently employed, with that view, as a wash for *chancres*. The preparation called *cuprum aluminatum* (*lapis divinus—pierre divine*) is made, according to the French Codex, by mixing, in powder, three ounces, each, of copper sulphate, potassium nitrate, and alum; heating the mixture in a crucible, so as to produce aqueous fusion, then mixing in a drachm of powdered camphor, and, finally, pouring out the whole on an oiled stone to congeal. The mass, when cold, is broken into pieces, and kept in a well-stoppered bottle. It is often desirable to employ copper sulphate, as a caustic, in the form of pencil. Its tendency to effloresce interferes with its use in this way in the pure state. Llovet recommends for the purpose a mixture of one part of potassa-alum and two of copper sulphate, which are to be first powdered, and then gradually melted together in a porcelain vessel, and poured into moulds made of bronze. (*Gaz. des Hôp.*, Juillet 28, 1863.) Another mode of preparing *pencils of copper sulphate* is to rub briskly together four parts of that salt and one of borax, and to mould the plastic mass which results, into the desired form. (*A. J. P.*, March, 1864, p. 106.) An elongated cone is the best form, made by selecting suitable crystals and turning them in a lathe to the desired form; or they may be made by filing the crystals, and finishing with sand-paper.

Dose, of copper sulphate, as an astringent, one-fourth of a grain (0.016 Gm.); as an

emetic, five grains (0.32 Gm.), repeated in fifteen minutes if necessary, but not oftener than once. As a stimulant wash, the solution may be made of the strength of two, four, or eight grains to the fluidounce of water. For its effects as a poison, see *Cuprum*.

CUPRUM.

COPPER

(cū'prūm)

Cu = 63.1

"Fine Copper wire, about No. 25 wire gauge, or about 0.02 inch." *Br.* 1885.

Cupreum Filum; Fil de Cuyvre, Cuivre, *Fr.*; Kupfer, Kupferdraht, *G.*; Rame, *It.*; Cobre, *Sp.*

This metal is very generally diffused in nature, and exists principally in four states; as native copper, as an oxide, as a sulphide, and as a salt. Its principal native salts are the silicate, carbonate, arsenate, and phosphate. In the United States it occurs in various localities, but especially in the neighborhood of Lake Superior, in Montana, Arizona, Alaska and East Tennessee. The principal producing copper mines of Europe are those of Spain and Portugal and of Mansfeld in Germany. Chili and Japan are also relatively large producers at present.

The total production of copper in the United States has increased very rapidly in recent years, and now is more than half of the world's annual production. It was, for 1902, 699,508,644 lbs., valued at \$90,936,124, and for 1903, 730,044,517 lbs., valued at \$94,905,787. The three most productive states are Montana, Michigan, and Arizona, in the order named. The consumption of copper in the United States for 1903 was 566,429,885 lbs., and the exports for the same year 310,729,524 lbs.

Properties.—Copper is a brilliant, sonorous metal, of a reddish color, and very ductile, malleable, and tenacious. It has a slightly nauseous taste, and emits a disagreeable odor when rubbed. Its texture is granular, and its fracture hackly. Its sp. gr. is 8.92 to 8.95, and its fusing point 1398° C. (2538° F.) according to Daniell, being intermediate between the fusing points of silver and gold. Its atomic weight is given at 63.5, or, according to the most accurate determinations, 63.1. Exposed to the air it undergoes a slight tarnish. Its combinations are numerous and important. With oxygen it forms two well characterized oxides, a red suboxide, better known as *cuprous oxide*, Cu₂O, and a black oxide, known as *cupric oxide*, CuO. While a cuprous chloride, iodide, and sulphide are known, it is the cupric oxide chiefly that unites with the several acids to form the copper salts. With metals copper forms numerous alloys, of which that with zinc, called brass, and that with tin, called bronze, are the most useful.

Characteristics.—Copper is recognized by its color, and the effects of tests on its solution in nitric acid. This solution, with potassium hydroxide, sodium hydroxide, and ammonia, yields a blue precipitate, soluble in excess of the latter alkali, with which it forms a deep azure-blue liquid. Potassium ferrocyanide occasions a brown precipitate of copper ferrocyanide, and a bright plate of iron immersed in the solution immediately becomes covered with a film of metallic copper.¹ Potassium ferrocyanide is a very delicate test for minute portions of copper in solution. Another test, proposed by Verguin, is to precipitate the copper in the metallic state on platinum by electrochemical action. For this purpose a drop of the (acid) liquid to be examined is placed on a slip of platinum foil, and a slip of bright iron is brought in contact with the platinum and the liquid. If copper be present it will be instantly precipitated on the surface of the platinum.

Action on the Animal Economy.—Copper in its pure state is nearly inert, but in combination it is highly deleterious. (For an account of the action of copper upon water see *Aqua*, page 162.) Nevertheless a minute portion of the metal has been found in the human body. According to Millon, copper, when it exists in the blood, is, like the iron, attached to the red corpuscles. To bring the copper into a state favorable for ready detection, he advises that the blood, as it escapes from a vein, be received in about three times its bulk of water, and the mixture poured into a bottle of chlorine and agitated. The whole, upon being rapidly filtered, furnishes a liquid in which copper is readily detected. Wackenroder found copper in the blood of man, but does not consider it a constant and normal constituent. He also detected this metal in the blood of domestic animals living on a mixed diet, but not in their blood when nourished on vegetable food only. (*Chem. Gaz.*, May 1, 1854.) It has been found in the feathers of certain birds, as of a grass-green paroquet from Australia, which is said to frequent districts of the country where copper is found. (*Ibid.*, Oct. 24, 1873, p. 212.) The soluble combinations of copper, when taken in poisonous doses, produce a coppery taste in the mouth; nausea and vomiting; violent pain in the stomach and bowels; frequent black and bloody stools; small, irregular, sharp, and frequent pulse; faintings; burning thirst; difficulty of breathing; cold sweats; paucity of urine, and burning pain in voiding it; violent headache; cramps, convulsions, and finally death. The best antidote is potassium ferrocyanide, given freely, which forms with the

poison the very insoluble copper ferrocyanide. Soap and alkalies are also antidotal. Before the antidote can be procured, large quantities of milk should be given and white of eggs mixed with water, which act favorably by forming copper caseinate and copper albuminate, but these compounds should be evacuated as soon as possible by vomiting and purging. Should vomiting not take place, the stomach tube may be employed. The symptoms of slow poisoning by copper are, according to Corrigan of Dublin, a cachetic appearance, emaciation, loss of muscular strength, colicky pains, cough without physical signs, and retraction of the gum, with a persistent purple edge, quite distinct from the blue edge produced by lead. (*Braithwaite's Retrospect*, Am. ed., xxx. 303.) But there is much doubt whether these symptoms can be produced by the metal. (See H. C. Wood's *Therapeutics*.)

In medico-legal examinations, where cuprous poisoning is suspected, Orfila recommends that the viscera be boiled in distilled water for an hour, and that the matter obtained by evaporating the filtered decoction to dryness be carbonized by nitric acid. The carbonized product will contain the copper. By proceeding in this way there is no risk of obtaining the copper which may happen to pre-exist in the animal tissues. This method of search is preferable to that of examining the contents of the stomach and intestines, from which copper may be absent, while it may have penetrated the different organs by absorption, especially the abdominal viscera.

Vessels of copper which are not coated with tin should not be used in pharmaceutical or culinary operations, for, although the metal uncombined is inert, yet the risk is great that the vessels may be acted on and a poisonous salt formed.

CUSPARIÆ CORTEX. Br.

CUSPARIA BARK

(cūs-pā'ri-æ cōr'tēx)

"The dried bark of *Cusparia febrifuga*, DC." Br.

Angustura, U. S. 1870; Angostura (Angostura) Bark, Carony Bark; Cortex Angusturæ; Angusture vrale, Fr. *Cod.*; Angusture, Fr.; Angusturarinde, G.; Corteccia dell' Angustura, It.; Corteza de Angostura, Sp.

This bark was dropped from the U. S. Pharmacopœia at the revision of 1880.

The subject of Angostura bark in its botanical relations has been involved in some confusion. The drug was at first supposed to be derived from a species of *Magnolia*, and was referred by some to *Magnolia virginiana* of this country. Humboldt and Bonpland were the first to throw light upon its true source. When at Angostura, a South American city on the Orinoco, they received specimens of the foliage of the plant from which the bark was obtained,

¹ Thoms (*Zeit. An. Chem.*, 94, 464) asserts that if to a solution too dilute to give a sensible reaction with potassium ferrocyanide be added a solution of potassium iodide, a yellow coloration is produced which becomes violet with starch paste. This test, in absence of deoxidizing agents, will show as little as 1 to 500,000.

and afterwards believed that they had found the same plant in a tree growing in the vicinity of Cumana. This latter they had the opportunity of personally inspecting, and were therefore enabled to describe accurately. Unable to attach it to any known genus, they erected it into a new one with the title of *Cusparia*, a name of Indian origin, to which they added the specific appellation of *febrifuga*. On their authority, *Cusparia febrifuga* was generally believed to be the true source of the medicine, and was recognized as such by the London College. A specimen having in the mean time been sent by them to Willdenow, the name of *Bonplandia* was imposed on the new genus by that celebrated botanist, and it was subsequently adopted by Humboldt and Bonpland themselves, in their great work on equinoctial plants. Hence the title of *Bonplandia trifoliata*, by which the tree is described in many works on *Materia Medica*. De Candolle, however, having found in the description all the characters of the genus *Galipea* of Aublet, rejected both these titles, and substituted that of *Galipea cusparia*, which was adopted by the London College, and for a time was retained in the British Pharmacopœia. But, after all these changes, it appears from the researches of Hancock, who resided for several months in the country of the Angostura bark tree, that it is doubtful whether the plant described by Humboldt and Bonpland is that which yields the drug, and not another species of the same genus. Among other striking differences between them is their different sizes, the tree described by Humboldt and Bonpland being at least sixty feet high, while that from which the bark is obtained is said to be never more than twenty feet. Hancock proposed for the plant of the Orinoco the title of *Galipea officinalis*, which was adopted in the U. S. P. 1870. This name was afterwards changed by Hancock to *Cusparia officinalis* (syn. *C. trifoliata*, H. et B., also (Willd.) Engl., and *Angostura Cusparia*, R. et Sch., of New Granada and Cumana), Fam. *Rutaceæ*; but at present the specific name *Angostura* of Richard seems to have precedence. *Bonplandia Angostura*, Rich., *Cusparia Angostura* (Rich.), Lyons.

Cusparia febrifuga, Humb.—*Cusparia officinalis*, Hancock, *Trans. Lond. Medico-Bot. Soc.—Galipea Cusparia*, St. Hilaire; B. & T., vol. i. 43.—This is a small tree, irregularly branched, rising to the medium height of twelve or fifteen feet, with an erect stem from three to five inches in diameter, and covered with a smooth gray bark. The leaves are alternate, petiolate, and composed of three leaflets, which are oblong, pointed at each extremity, from six to ten inches in length, from two to four in breadth, and supported upon the common petiole by short leafstalks. They are very smooth and glossy, of a vivid green color, marked occasionally with small whitish round spots, and, when fresh, of a strong odor resem-

bling that of tobacco. The flowers are numerous, white, arranged in axillary and terminal peduncled racemes, and of a peculiar unpleasant odor. The fruit consists of five bivalve capsules, of which two or three are commonly abortive. The seeds, two of which are contained in each capsule, one often abortive, are round, black, and of the size of a pea. The tree grows abundantly on the mountains of Carony, between the 7th and 8th degrees of N. latitude, and is well known in the missions near the Orinoco, upwards to two hundred miles from the ocean. It flourishes at the height of from six hundred to one thousand feet above the level of the sea. Its elegant blossoms, which appear in vast profusion in August and September, add greatly to the beauty of the scenery.

The bark is generally brought from the West Indies packed in casks; but, according to Brande, the original package as it comes from Angostura consists of the leaves of a species of palm, surrounded by a net-work of sticks.

Properties.—"Occurs in flattened or curved pieces, or in quills, generally about four or five inches (ten or twelve centimetres) long, an inch (twenty-five millimetres) wide, and one-twelfth of an inch (two millimetres) thick. The outer layer usually consists of a gray or yellowish cork which is often soft and easily removed, disclosing a hard, dark brown inner layer; the inner surface is light brown and frequently laminated. The fracture is short and resinous; on the fractured surface many white points are visible. A transverse section exhibits numerous cells filled with acicular crystals of calcium oxalate and small oil glands, but seldom any sclerenchymatous tissue other than small isolated groups of bast fibres. Odor musty; taste bitter." *Br.* Calcium oxalate raphides are abundant in the bark, but the most characteristic peculiarity is the presence of numerous cells a little larger than the other parenchymatous cells and completely filled with oil or a yellowish resin. The odor of Angostura bark is peculiar and disagreeable when fresh, becoming fainter with age; the taste is bitter and slightly aromatic, leaving a sense of pungency at the end of the tongue. According to Fischer, it contains volatile oil, bitter extractive, a hard and bitter resin, a soft resin, a substance analogous to caoutchouc, gum, lignin, and various salts. Oberlin and Schlagdenhauffen (1878) found in the bitter extractive an alkaloid, *angosturine*, $C_{10}H_{14}NO_{14}$, which melts at $85^{\circ} C.$, is crystallizable, and is turned red by pure sulphuric acid, and green by sulphuric acid with admixture of nitric acid. The volatile oil, which may be obtained by distillation with water, is of a pale yellowish color, lighter than water, of an acrid taste, and with the odor of the bark. Beckurts and Froeger (Gildemeister and Hoffman, *Ätherische Oele*, p. 601) found as its essential ingredient a sesquiterpene alcohol, $C_{15}H_{26}O$, to

which they give the name *galipol*. It boils between 260° and 270° C. and is optically inactive. *Cadinene*, $C_{15}H_{24}$, is also present and gives left rotatory character to the oil. A small quantity of an inactive sesquiterpene, *galipene*, is also present, as well as traces of a terpene which is probably *pinene*. The *cusparine* of Saladin has not been found by other investigators. Beckurts and Nehring (*A. J. P.*, 1892, 410) announced the discovery of four alkaloids in *Angustura* bark,—viz., *galipine*, $C_{30}H_{42}NO_3$, melting at 115.5° C. (240° F.) and crystallizing in slender lustrous needles of white color; *galipidine*, $C_{19}H_{19}NO_3$, melting at 111° C. (231.8° F.) and crystallizing in silky lustrous plates of white color; *cusparine*, $C_{30}H_{42}NO_3$ ($C_{19}H_{17}NO_3$, Körner), melting at 89° C. (192.2° F.) and readily soluble in alcohol, ether, chloroform, acetone, and benzene, more sparingly in light petroleum; and *cusparidine*, $C_{19}H_{17}NO_3$, melting at 78° C. (172.4° F.) and crystallizing in minute slender white needles. Its salts are less soluble than those of *galipine* and *galipidine*, but more readily than those of *cusparine*. The four alkaloids are tertiary bases. (See also *A. Pharm.*, 233 (1895, No. 6), 410.) Beckurts and Nehring also extracted the essential oil, amounting to 1.5 per cent. It had a sp. gr. at 15° C. (59° F.) of 0.956. Distilled under a pressure of 35 Mm. it commenced to boil at 153° C. (307.4° F.) and the greater part distilled between 200° and 220° C. (392° to 428° F.) the last portions becoming solid when artificially chilled. (See also *A. Pharm.*, 1897, 518.) They found the bitter principle *angosturine*, which when purified was white and melted at 58° C. (136.4° F.). A glucoside was also found, the solution of which fluoresced; but it was not fully investigated.

A. T. Thompson states that precipitates are produced with the infusion by the solutions of ferrous sulphate, antimony and potassium tartrate, copper sulphate, lead acetate and subacetate, mercuric chloride, silver nitrate, and pure potassium hydroxide, by nitric and sulphuric acids, and by the infusions of galls and yellow cinchona; but how far these substances are medicinally incompatible with the bark it would be difficult to determine.¹

¹ FALSE *ANGUSTURA* BARKS.—Under this title, European writers describe a poisonous bark which was introduced on the Continent mixed with true *Angustura* bark. It is distinguished by its greater thickness, hardness, weight, and compactness; by its resinous fracture; by the appearance of its epidermis, which is sometimes covered with a ferruginous efflorescence, sometimes in yellowish gray and marked with prominent white spots; by the brownish color and smoothness of its internal surface, which is not like that of the genuine bark, separable into laminae, by the yellowish white powder which it yields; by its total want of odor, and its intense tenacious bitterness. When steeped in water it does not become soft like the true *Angustura*. Pelletier and Caventou found it to contain *brucine*. (See *Nux Vomica*.) In consequence of the presence of this principle, a drop of nitric acid upon the internal surface of the bark produces a deep red spot. The same acid, applied to the external surface renders it emerald-green. In true *Angustura* bark a dull red color is produced by the acid on both surfaces. The false *Angustura* was at first supposed to be derived from

Uses.—*Angustura* bark has long been used by the natives² of South America and the West Indies as a stimulant tonic. In large doses it also evacuates the stomach and bowels, and is often employed for this purpose in South America. It is said to be peculiarly efficacious in bilious *diarrhoeas* and *dysenteries*, and has been recommended in *dyspepsia* and other diseases requiring a tonic treatment. The testimony, however, of practitioners in Europe and the United States is not strongly in its favor, and it is probably better adapted to tropical diseases than to those of temperate climates.

It may be given in powder, infusion, tincture, fluidextract, or extract.

Dose, of the extract, five to fifteen grains (0.32 to 1 Gm.), which, however, according to Hancock, is inferior to the powder or infusion. To obviate nausea, it is frequently combined with aromatics. (See *Infusum Cuspariæ*.)

Dose, in substance, ten to thirty grains (0.65 to 2.0 Gm.). In larger quantities it is apt to produce nausea.

Hagenia abyssinica, Gmelin, B. & T. 102.—*Brayera anthelmintica*,³ Kunth; De Cand., *Pro-*

Brucea ferruginea, L'Herit, B. *antidysenterica*, Lam., but at present is ascribed to *Strychnos Nux vomica*. (See also *A. J. P.*, 1892, 115, and P. J., 1895, 722.) An alkaloid, *brucamarine*, has been separated from *Brucea sumatrana*, Roxb.

Brazilian Angustura Bark, the product of *Esenbeckia febrifuga*, A. Juss, consists of slightly curved pieces 8 to 10 inches long, about $\frac{1}{4}$ of an inch in thickness, of a persistently bitter taste. The outer surface is usually ashen gray, and always marked with longitudinal red or black spots on a yellow ground; the inner surface is reddish with paler, distinct, elongated fibres. On maceration the bark does not swell. (Oberlin and Schlagdenhaufen, J. P. C., xxviii.)

Columbia Angustura Bark.—From time to time a false *angustura* bark, supposed to be a product of *Angustura brasiliensis* or *Cusparia trifoliata* from Columbia, has appeared in the London market. For minute description see P. J., August, 1903. In this bark, E. W. Pollard has found besides fixed and volatile oil, a bitter amorphous alkaloid, whose physiological activities have not been tested. This bark is especially distinguished from true *angustura* by the large and numerous concentrically arranged groups of sclerenchymatous cells, revealed by the microscope in its transverse section.

² According to *Indes Kewensis*, *Brayera anthelmintica*, Kunth, is the correct name. *Hagenia abyssinica*, Gmelin, the synonym, the genus *Hagenia* not being acknowledged.

drom., ii, 580; Pereira, *Mat. Med.*, 3d ed., ii, 1818.—*Bankia abyssinica*, Bruce.—This is a tree about twenty feet high, growing on the table-land of Abyssinia, at an elevation of from three thousand to eight thousand feet. The branches exhibit circular cicatrices, left by the fallen leaves. These are crowded near the ends of the branches, large, pinnate, sheathing at the base, with opposite, lanceolate, serrate leaflets, villose at the margin, and nerved beneath. The unisexual flowers are tinged with purple, pedicelled, with an involucre of four roundish, oblong, obtuse, membranous bracts, and are arranged in fours, upon hairy, flexuous, bracteate peduncles, with alternate branches. They are small and of a greenish color, becoming purple. These and the unripe fruit are the parts of the plant employed. The petals are apt to be wanting in the dried flowers. They are brought from Abyssinia packed in boxes, reaching Europe chiefly by way of Aden and Bombay. The Abyssinian name of the medicine has been variously spelled by European writers kosso, koosso, cusso, cosso, etc. The fruit of the tree is said to be used as an anthelmintic in Abyssinia, but Dragendorff failed to detect any active principle in it.¹

Properties.—The dried flowers are in unbroken though compressed clusters. The male flowers are usually collected, so that ordinarily the general color of the mass is greenish yellow or light brown; sometimes the female flowers constitute the bulk of the drug, which then has a distinct reddish tint, and is often known in commerce as *red kouso*. In accordance with our Pharmacopœia, this commercial variety should alone be used. The male flowers are often found mixed with the female flowers, when loose (not in bundles), as high as 12 per cent. of this adulteration having been noticed by Meyer and Sandlund. (*Ph. Ztg.*, 1893, No. 99.) The official description is as follows: "In rolls or compressed bundles from 25 to 40 Cm. long, reddish-brown, each branch arising from the axil of a sheathing bract, and each flower furnished at its base with two rounded bracts; calyx-tube top-shaped, pubescent, and bearing a circle, resembling an outer calyx, of five rigid, spreading, obovate, purple-veined bracts, which are larger than the five usually shrivelled and incurved oval calyx-lobes; the five caducous petals usually absent in the drug; carpels two; styles exserted and stigmas broad and hairy; odor slight; taste bitter. The large stems should be rejected." *U. S.* As the medicine, from its high price, is apt to be adulterated, it should be procured in the unpowdered state, in which the botanical characters of the flower will sufficiently test its genuineness. It has a fragrant balsamic odor, and the taste, slightly perceptible at first, be-

comes in a short time somewhat acrid and disagreeable. Analyzed by Wittstein, it was found to contain, in 100 parts, 1.44 of fatty matter and chlorophyll, 2.02 of wax, 6.25 of bitter acrid resin, 0.77 of tasteless resin, 1.08 of sugar, 7.22 of gum, 24.40 of tannic acid, 40.97 of lignin, 15.71 of ashes, with 0.14 part of loss. In 1855 it was studied by Clemens Willing (*Ch. Cb.*, 1855, 224), who found a small quantity of tannin, volatile oil, crystallizable acid, and a bitter resin. In 1858 Pavesi (*Viertelj. f. Prak. Pharm.*, viii, 505) made a further chemical study of the drug; but we are chiefly indebted to Bedall of Munich, for determining that the bitter acrid resin of Wittstein is equivalent to the *teniin* of Pavesi, and for the name of *kosin*. It may be obtained by treating kouso repeatedly with alcohol to which calcium hydroxide has been added; the residue is boiled with water, the liquids are mixed, filtered, and distilled, and the residue treated with acetic acid, which precipitates the kosin in a white flocculent form, soon becoming denser and resin-like, and, on drying, yellowish, or, at a higher temperature, brown. The product is 3 per cent. In bulk, kosin has an odor like that of Russian leather, a persistent bitter and acrid taste, a yellowish or yellowish-white color, and an indistinct crystalline appearance under the microscope. It is very sparingly soluble in water, but freely so in alcohol, ether, and alkaline solutions. (*A. J. P.*, 1872, 394.) Its formula, according to Flückiger, is $C_{31}H_{58}O_{10}$. It fuses at 142° C. (287.6° F.), and remains after cooling an amorphous yellow mass, but if touched with alcohol it immediately assumes the form of stellate tufts of crystals. This may be repeated at pleasure, kosin not being altered by cautious fusion. (*Pharmacog.*, 2d ed., 258.) Leichenring (*A. Pharm.*, 1894, 50) has re-examined kouso, and finds an inactive crystalline principle to which he gives the name *protokosine*, and an amorphous substance, *kossotoxine*, which he considers the active principle of the drug; the latter is a yellowish powder, fusing at 80° C., and not obtainable in a crystalline state. It is easily soluble in alcohol, ether, benzene, carbon disulphide, and insoluble in water.

Sodium kosinate has been recommended by Pavesi as a very eligible preparation for obtaining the virtues of kosin; a process is given in *Am. Drug.*, 1884, 96; *A. J. P.*, 1885.

Uses.—Kosso is highly valued in Abyssinia as a vermifuge. Bruce speaks of it in his travels, and gives a figure of the plant. Brayer, a French physician practicing in Constantinople, published a treatise on it at Paris in 1823. It was in his honor that Kunth adopted the generic title of the plant. Much attention has been attracted to this valuable medicine, and trials made with it have proved that it has extraordinary efficacy in the destruction and expulsion of the *tape-worm*. Its effects when taken internally are not very striking. In the ordinary dose it sometimes

¹It is stated that in Abyssinia, honey gathered directly after the flowering season from beehives in gardens planted with kouso plants, is used in doses of a teaspoonful as a very effective tenicide.

produces heat of stomach, nausea, and even vomiting, and shows a tendency to act on the bowels, though this effect is not always produced. It appears to act exclusively as a poison to the worms, and has been found equally effectual in both kinds of tape worm. The medicine is taken in the morning upon an empty stomach, a light meal having been made the preceding evening. A previous evacuation of the bowels is also recommended. The flowers are given in the form of powder, mixed with half a pint of warm water, the mixture being allowed to stand for fifteen minutes, then stirred up, and taken in two or three draughts at short intervals. The medicine may be preceded and followed by lemonade. The medium dose for an adult is half an ounce (15.5 Gm.), which may be diminished one-third for a child of twelve years, one-half for one of six years, and two-thirds for one of three years. Should the medicine not act on the bowels in three or four hours, a brisk cathartic should be administered. One dose is said to be sufficient to destroy the worm. Should the quantity mentioned not prove effectual, it may be increased to an ounce (31 Gm.).

Pure koin has been considerably used in Germany in doses of thirty grains (2 Gm.), taken in two or four powders; but Buchheim found pure koin less powerful as an anthelmintic than that which was not pure, while Arena (*Ph. Z. R.*, 1879, 655) believes that koin is not the active principle at all, but that the activity of kouso resides exclusively in the green, slightly bitter resin, which is soluble in alcohol and ether. If this view be correct, it explains the greater efficacy of freshly powdered kouso, for the green resin turns yellow by age and loses its power, and Arena's investigations further indicate that the amorphous koin of commerce is preferable to the pure principle. It is a yellowish-brown mass, which may be given in doses of from seven to fifteen grains (0.45 to 1.0 Gm.), repeated every half hour until four doses are taken, to be followed in an hour by a full dose of castor oil. So far as we know, no cases of poisoning by kouso or its active principle are on record, but it has been found by Rochebrune to be capable of causing centric convulsions in the lower animals.

Dose, of kouso, half an ounce (15.5 Gm.); of koin, seven to fifteen grains (0.45 to 1.0 Gm.).

CYPRIPEDIUM. U. S.

CYPRIPEDIUM [Lady's Slipper]

(cýp-ri-pě'di-üm)

"The dried rhizome and roots of *Cypripedium hirsutum* Miller (*Cypripedium pubescens* Willdenow) or of *Cypripedium parviflorum* Salisbury (Fam. *Orchidaceæ*)." U. S.

Rhizoma Cypripedii; Yellow Lady's Slipper Root, Yellow Indian Shoe, Yellow Moccasin Flower, Yellow Noah's Ark, Venus' Shoe, Male Nerveine, American Valerian; Racine de Cypripède jaune, Valériane américaine, Fr.; Gelbfrauenschuhwurzel, G.

Under the common name of *lady's slipper*, or *moccasin plant*, several species of *Cypripedium* inhabit the woods in different parts of the United States. They are small plants, with large, many-nerved, plaited leaves, sheathing at the base, and large often beautiful flowers, of a shape not unlike the Indian moccasin, whence they derive one of their common names. Their generic name of *Cypripedium* (Κύπρις, *Venus*, and πόδιον, *sock*) had a similar origin. Several of them have been used by American physicians, the root being the part employed. R. P. Stevens of Ceres, Pennsylvania, says of them that he has found the *C. reginæ*, Walt. (*C. spectabile*, Salisb.), and *C. acaule*, Ait., especially when growing in dark swamps, to be possessed of narcotic properties, and to be less safe than the *C. parviflorum*, Salisb., which is gently stimulant with a tendency to the nervous system, and is quite equal to valerian. He has employed it advantageously in *hysteria*, and in the pains of the joints, following scarlet fever. (*N. Y. Journ. Med.*, iv. 359.) E. Ives considers *C. hirsutum*, Mill., and *C. reginæ*, Walt., identical in their effects, but *C. reginæ* more powerful (*Trans. Am. Med. Assoc.*, iii. 312). The roots of the two species, *C. hirsutum* and *C. parviflorum* are indiscriminately found in commerce and sold under the same name.

Cypripedium hirsutum, Mill., *Gard. Dict.*, 1768.—*C. pubescens*, Willd., *Sp. Plant.*, 1805, iv. 142.—The *yellow lady's slipper*, as this plant is called from the color of its flowers, has a simple often flexuous, pubescent, leafy stem, from one to two feet high. The leaves are pubescent, ovate-lanceolate, acuminate, narrowing at the base, about four or five inches long by two in breadth, alternate, sessile, and sheathing. The flower is usually solitary and terminal, with four divisions of the perianth, the two outer cohering nearly to the apex, the inner longer, narrower, undulatory or twisted, and the lip an inch or two in length, swelling sac-like, and of a yellow color. The fruit is an oblong capsule, tapering at each end, recurved, pubescent, and peduncled. The plant is indigenous, growing abundantly in rich, moist woods throughout the United States.

Cypripedium parviflorum, Salisbury, *Lady's Slipper*. *Small-flowered Yellow Lady's Slipper*.—This is a perennial plant with a leafy stem, a foot or two in height, and comparatively small yellowish-green flowers, appearing in May. The specific character of the flower, which is that also of the plant, is that the lobe of the style is triangular and acute; the outer petals are oblong-ovate and acuminate; the inner linear and contorted; the lips shorter than the petals, and compressed. This species grows extensively through the United States, south of the Potomac, east and west of the Alleghanies, and in several of the Northern States, particularly New York, Michigan, Connecticut and Vermont.

"Rhizome of horizontal growth, curved, 3 to 10 Cm. long, 2 to 6 Mm. thick, orange-brown to dark-brown, the upper side beset with numerous circular, cup-shaped scars, closely covered below with simple wiry roots varying from 3 to 15 Cm. in length; fracture of rhizome short, white, that of roots somewhat fibrous; odor distinct, heavy, valerian-like; taste sweetish, bitter, and somewhat pungent." *U. S.* Maisch gives a distinctive description of the roots of the two species, of which the following is a condensed account. Of *C. hirsutum*, Mill., the rhizome is almost horizontal, in its greatest length nearly four inches, slightly bent with a shallow downward curve, from one-eighth to three-sixteenths of an inch thick, with numerous deeply concave scars left by the stems, having fully the width of the rhizome. The rootlets are numerous, several inches in length, sometimes even nine inches or more, about one-fourteenth of an inch thick, without branches, somewhat undulate, and, though attached to the rhizome on all sides, are abruptly turned downward, owing to its horizontal position in the ground. Their color is yellowish brown, becoming much darker on drying, which causes longitudinal wrinkles. The cortical part of both species is colored blue by iodine. The rhizome of *C. parviflorum* is altogether different from the former, being bent nearly at right angles three or four times, each section about $\frac{3}{4}$ of an inch long, and the whole length, while only about two inches in a straight line from end to end, is yet actually three inches along the course of the rhizome. This is about $\frac{1}{2}$ of an inch thick, and has stem-scars about the same in width, with about three in each bend. The rootlets, which are attached to all sides of the rhizome, are numerous, four to six inches long, less undular than those of *C. hirsutum*, Mill., and of a brighter color, being a decided orange-brown when fresh, and changing little on drying. (*A. J. P.*, 1872, 297.) Poisonous properties have been attributed to *C. reginae*, Salisb., and *C. hirsutum*, Mill. (see *Geol. Nat. Hist. Survey, Minnesota Bull.*, 9, part i.), but it has been shown that the secretion from the glandular hairs simply exerts an irritant action.

Senega and hydrastis roots are sometimes found accidentally mixed with those of cypripedium, probably from the plants having a common habitat.

Properties.—Cypripedium has a somewhat aromatic odor, which diminishes by time, and a bitter, sweetish, peculiar, and in the end somewhat pungent taste. It yields its virtues to water and alcohol. The root has been analyzed by Henry C. Blair, who found it to contain a volatile oil, a volatile acid, tannic and gallic acids, two resins, gum, glucose, starch, and lignin. (*A. J. P.*, 1866, p. 494.) The eclectic preparation *cypripedin* is said to be a resinoid, obtained by precipitating with water a concentrated tincture of the rhizome. The substance thus obtained is complex, and has no claim to the name given it, which ought to be

reserved for the active principle when discovered. It is probable that the virtues of the rhizome reside in a volatile oil and a bitter principle.

Uses.—Cypripedium appears to be a gentle nervous stimulant or antispasmodic, and has been used for the same purposes as valerian, though less powerful. E. Ives of New Haven, Conn., commends the remedy in *hypochondriasis* and *neuralgia*. It may be used in powder, infusion, or tincture.

Dose, of the powder, fifteen grains (1 Gm.), three times a day. The resinoid, obtained by precipitating the tincture, has been given in doses varying from half a grain to three grains (0.032 to 0.20 Gm.).

Off. Prep.—Fluidextractum Cypripedii, *U. S.*

DECOCTA. U. S.

DECOCTIONS

(dê-côc'tà)

Tisanes par décoction, Décoctions, *Fr.*; Abkochungen, *G.*; Decotti, *It.*; Cocimiento, *Sp.*

Decoctions are solutions of vegetable principles, obtained by *boiling* the substances containing these principles in water. Vegetables generally yield their soluble ingredients more readily, and in larger proportion, to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapor over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a rule, be long continued, as the ingredients of the vegetable are apt to react on one another, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fibre. Should the physician not happen to prescribe this preliminary comminution, the pharmacist should not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavorable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble or but slightly soluble in cold water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure, the preparation. In all these instances, infusion is preferable to

decoction. Besides, by the latter process more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place and the liquid is rendered turbid, and this constitutes the greatest objection to this class of preparations. When the active principle is thus dissolved in excess, the decoction should always be strained while hot, so that the matter which separates on cooling may be mixed again with the fluid by agitation at the time of administering the remedy. In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a rule, glass or earthenware vessels should be preferred, as those made of metal are sometimes corroded by the ingredients of the decoction, which thus become contaminated. Vessels of clean cast-iron or common tin, or of block tin, are preferable to those made of copper, brass, or zinc; but iron pots should not be used where astringent vegetable substances are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, when the weather is warm, for a longer period than forty-eight hours.

The tendency of modern medicine and pharmacy has been decidedly against the employment of decoctions; their nauseous taste, bulky dose, repulsive appearance, and non-permanent character have been powerful reasons for causing their retirement, while the use of tinctures and fluidextracts has largely increased. In the 1880 revision of the U. S. Pharmacopœia the number of official decoctions was reduced to two, and a general formula was appended for the guidance of the pharmacist. The U. S. P. 1890 reduced the strength of the general formula for decoctions from 10 per cent. to 5 per cent, and this strength was retained in the Eighth Revision of the U. S. P., as will be seen from the following: "An ordinary Decoction, the strength of which is not directed by the physician, shall be prepared by the following formula: Take of *The Substance, coarsely comminuted, *fifty grammes* [or 1 ounce av., 334 grains]; Water, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Introduce the Substance into a suitable vessel provided with a cover, pour upon it *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of cold Water, cover it well, and boil for fifteen minutes. Then allow it to cool to about 40° C. (104° F.), express, strain the expressed liquid, and pass enough cold

Water through the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].

Caution.—The strength of Decoctions of energetic or powerful substances should be specially prescribed by the physician." U. S.

The two decoctions of the U. S. P. 1890, *Decoctum Cetrariæ* and *Decoctum Sarsaparillæ Compositum*,¹ were both dismissed in the Eighth Revision and only the general formula retained.

¹*Decoctum Sarsaparillæ Compositum*, U. S. 1890. *Decoctum Sarsæ Compositum*, Br. 1885.—Under the name of *Lisbon Diet Drink* a preparation was at one time so largely used in chronic syphilis that its imitation under the above names was recognized both in the Br. and U. S. Pharmacopœia as Compound Decoction of Sarsaparilla. The formula of the U. S. Pharmacopœia of 1890 was as follows: "Sarsaparilla, cut and bruised, *one hundred grammes* [or 3 ounces av., 230 grains]; Sassafras, in No. 20 powder, *twenty grammes* [or 308 grains]; Gualacum Wood, rasped, *twenty grammes* [or 308 grains]; Glycyrrhiza, bruised, *twenty grammes* [or 308 grains]; Mezereum, cut and bruised, *ten grammes* [or 154 grains]; Water, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms.]. Boil the Sarsaparilla and Gualacum Wood for half an hour in a suitable vessel with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water. Then add the Sassafras, Glycyrrhiza, and Mezereum, cover the vessel well, and macerate for two hours. Finally strain, and add enough cold Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890.

Compound Decoction of Sarsaparilla was at one time very largely used as an alternative in secondary syphilis and chronic rheumatism, especially as an adjuvant to mercurials and iodides. It was given in doses of from four to six fluidounces (120 to 180 Cc.) served desuetude. The *Decoction of Zittmann* (*Decoctum Zittmanni*) is a preparation of Sarsaparilla much used in Germany for similar purposes as our compound decoction of sarsaparilla; and, as it has attracted some attention in this country as a remedy in obstinate ulcerative affections we give the formula of the German Pharmacopœia, which is generally followed in its preparation. *Decoctum Sarsaparillæ Compositum Fortius*, P. G. [*Zittmann's Stronger Decoction*.] Stärkeres Zittmannsches Decoct.—"Take of Sarsaparilla root, cut, *one hundred parts*; pour upon it common water, *two thousand six hundred parts*, digest for twenty-four hours; then add of sugar powdered, alum powdered, each, *six parts* and heat them in a covered vessel, in a steam bath, for three hours, stirring frequently. Towards the end of the boiling, add of anise bruised, fennel seed bruised, each, *four parts*; senna cut, *twenty-four parts*; liquorice root cut, *twelve parts*. Strain by expression, and set aside for a short time. The clear decanted liquid should be *two thousand five hundred parts*. When not otherwise directed, a colature of two thousand five hundred grammes is divided into eight portions.

N. B.—When Decoction Zittmanni is prescribed, it is prepared in a similar manner, except that to the sugar and alum are added of mild chloride of mercury, *four parts*; cinnabar (red sulphide of mercury), *one part*, enclosed in a linen bag." P. G.

Decoctum Sarsaparillæ Compositum Mitius, P. G. [*Zittmann's Milder Decoction*.] Milderes Zittmannsches Decoct.—"Take the residue of the stronger decoction and sarsaparilla root, cut, *fifty parts*; pour upon them common water, *two thousand six hundred parts*, and expose to the heat of a steam bath for three hours in a covered vessel, stirring frequently. Towards the end of the operation add of lemon peel, cassia bark, small cardamoms, liquorice root, each, cut and bruised, *three parts*. Strain by expression, and set aside for a short time. The clear decanted liquid should be *two thousand five hundred parts*. When not otherwise directed, a colature of two thousand five hundred grammes is divided into eight portions." P. G. Mercury was detected by Wiggers in this decoction in very small proportion. It should not be prepared in metallic vessels, lest the mercurial in solution should be decomposed. The decoction may be drunk freely.

DECOCTUM ALOES COMPOSITUM. Br.

COMPOUND DECOCTION OF ALOES

(ḍe-cōc'tūm āl'ō-ēs cōm-pōs'ī-tūm)

Tisane (Décocté) d'Aloës composée, *Fr.*; Zusammengesetztes Aloëdecoct, *G.*

"Extract of Barbados Aloes, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Myrrh, Saffron, Potassium Carbonate, of each, $\frac{1}{2}$ ounce (Imp.) or 5 grammes; Extract of Liquorice, 2 ounces (Imp.) or 40 grammes; Compound Tincture of Cardamoms, 15 fl. ounces (Imp. meas.) or 300 cubic centimetres; Distilled Water, a sufficient quantity. Reduce the Extract of Barbados Aloes and the Myrrh to coarse powder, and boil them and the Potassium Carbonate and the Extract of Liquorice with one pint (Imp. meas.) or four hundred cubic centimetres of Distilled Water in a covered vessel for five minutes; add the Saffron; when the liquid is cool add the Tincture of Cardamoms; set aside in the covered vessel for two hours; strain through flannel; pass sufficient Distilled Water through the strainer to make fifty fluid ounces (Imp. meas.) or one thousand cubic centimetres of the Compound Decoction of Aloes." *Br.*

This is essentially the former process of the British Colleges. The direction is properly given to rub the aloes, myrrh, and potassium carbonate together before the addition of the other ingredients. The effect of the alkaline carbonate is, by combining with the resin of the myrrh and the insoluble portion of the aloes, to render them more soluble in water, while the licorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition. This decoction is said not to filter clear when first made, but, if kept for some time, to deposit insoluble matter, and then to become bright and clear on filtering. (*P. J.*, xiv. 491.) *J. F. Brown* proposes to prepare a concentrated decoction which keeps for a long time unchanged. (*C. D.*, 1896, 425.)

Long boiling impairs the purgative property of aloes, and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself; it is also more tonic and cordial, from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the potassium carbonate. It is given as a gentle cathartic, tonic, and emmenagogue, and is especially useful in *dyspepsia*, *habitual constipation*, and *atonic amenorrhœa*. The decoction should not be combined in prescription with acids, acidulous salts, or other bodies incompatible with the alkaline carbonate.

Dose, from one-half to two fluidounces (15 to 60 Cc.).

DECOCTUM GRANATI CORTICIS. Br.

DECOCTION OF POMEGRANATE BARK

(ḍe-cōc'tūm grā-nā'tī cōr'tī-cīs)

Decoctum Granati Radicis, *Br.* (1885); Decoction Corticis Radicis Granati; Apozème d'Ecorce de Racine de Grenadier, *Fr. Cod.*; Granatwurzelrinden-Abkochung, *G.*

"Pomegranate Bark, in No. 10 powder, 4 ounces (Imperial) or 200 grammes; Distilled Water, a sufficient quantity. Boil the Pomegranate Bark with twenty-four fluid ounces (Imp. meas.) or twelve hundred cubic centimetres of Distilled Water in a suitable vessel for ten minutes; strain; pour enough Distilled Water over the contents of the strainer to make one pint (Imp. meas.) or one thousand cubic centimetres of the strained Decoction." *Br.*

This decoction has double the quantity of bark in the *Br. Pharm.* 1898 over the *Br. Pharm.* 1885, the quantity of root bark in the latter for one pint being two ounces.

For the uses of this decoction, see *Granati Cortex*.

Dose, one-half to two fluidounces (15 to 60 Cc.).

DECOCTUM HÆMATOXYLI. Br.

DECOCTION OF LOGWOOD

(ḍe-cōc'tūm hæ-mā-tōx'y-lī)

Tisane (Décocté) de Bois de Campêche, *Fr.*; Blauholz-Abkochung, *G.*

"Logwood, in chips, 1 ounce (Imperial) or 50 grammes; Cinnamon Bark, bruised, 70 grains (Imp.) or 8 grammes; Distilled Water, a sufficient quantity. Boil the Logwood with twenty-four fluid ounces (Imp. meas.) or twelve hundred cubic centimetres of Distilled Water in a suitable vessel for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; pour enough Distilled Water over the contents of the strainer to make one pint (Imp. meas.) or one thousand cubic centimetres of the strained Decoction." *Br.*

We prefer the old U. S. formula, which ordered an ounce of the logwood to be boiled with two pints down to a pint, and doubt much whether the wood is exhausted by a boiling of ten or fifteen minutes. The cinnamon of the *Br.* formula is in general a very suitable addition, but there might be circumstances under which it would be better omitted, and in this case, as in others, any addition to the simple decoction might be left to the judgment of the prescriber.

This is an excellent astringent in *diarrhœas* of relaxation.

Dose, for an adult, two fluidounces (60 Cc.); for a child about two years old, two or three fluidrachms (7.5 to 11.25 Cc.).

DIGITALIS. U. S. (Br.)

DIGITALIS [Foxglove]

(dĭ-jĭ-tālĭs)

"The dried leaves of *Digitalis purpurea* Linné (Fam. *Scrophulariaceæ*), collected from plants of the second year's growth, at the commencement of flowering." U. S. "The dried leaves of *Digitalis purpurea*, Linn. Collected from plants commencing to flower." Br.

Digitalis Folia, Br. Digitalis Leaf; Digitalis Leaves, Foxglove Leaves; Fairy Cap, Fingers, Thimbles, or Bells, Lady's Glove, Purple Foxglove, Flop-dock, Throatwort, Cottagers; Digitale, *Fr. Cod.*; Feuilles de Digitale Pourprée (de grande Digitale), Digitale Pourprée, Doigtier, *Fr.*; Folia Digitalis, *P. G.*; Purpurrother Fingerhut, Fingerhutkraut, Fingerhutblätter, *G.*; Digitale, *It.*; Digital (Hoja de), Dedalera, *Sp.*

Digitalis purpurea (L.), Willd., *Sp. Plant.* iii. 383; Woodv., *Med. Bot.*, p. 218, t. 78.—The foxglove is a beautiful plant, with a biennial or perennial fibrous root, which in the first year sends forth large tufted leaves, and in the following summer a single erect, downy, and leafy stem, rising from two to five feet, and terminating in an elegant spike of purple flowers. The lower leaves are ovate, pointed, about eight inches in length and three in breadth, and stand upon short, winged footstalks; the upper are alternate, sparse, and lanceolate; both are obtusely serrate, and have wrinkled velvety surfaces, of which the upper is a fine deep green, the under paler and more downy. The flowers are numerous, and attached to the upper part of the stem by short peduncles, in such a manner as generally to hang down upon one side. At the base of each peduncle is a floral leaf, which is sessile, ovate, and pointed. The calyx is divided into five segments, of which the uppermost is narrower than the others. The corolla is monopetalous, bell-form, swelling on the lower side, irregularly divided at the margin into short obtuse lobes, and in shape and size not unlike the end of the finger of a glove, a circumstance which has suggested most of the names by which the plant is designated in different languages. Its mouth is guarded by long soft hairs. Externally, it is in general of a bright purple; internally, it is sprinkled with black spots upon a white ground. There is a variety with white flowers. The filaments are white, curved, and surmounted by large yellow anthers. The style is simple, and supports a bifid stigma. The seeds are numerous, very small, grayish brown, and contained in a pyramidal two-celled capsule.¹

Foxglove grows wild in the temperate parts of Europe, where it flowers in the middle of

summer. In this country it is cultivated both for ornament and for medicinal use. The leaves are the part generally employed. Much care is requisite in selecting, preparing, and preserving them, in order to insure their activity. They should be gathered in the second year, immediately before or during the period of inflorescence, and those only chosen which are full-grown and perfectly fresh (Geiger); but the observations of F. Schneider would lead to the conclusion that they are much stronger when not gathered before the latter part of summer or the beginning of autumn. (*A. J. P.*, 1870, p. 221.) It is said that those plants are preferable which grow spontaneously in elevated places exposed to the sun. (Duncan.) As the leafstalk and midrib are comparatively inactive, they may be rejected. Withering recommends that the leaves should be dried either in the sunshine, or by a gentle heat before the fire, and care should be taken to keep them separate while drying. Pereira states that a more common and, in his opinion, a preferable mode is to dry them in a basket in a dark place in a drying stove. It is probably owing, in part, to the want of proper attention in preparing digitalis for the market that it is often inefficient. The dried leaves should be kept in tin canisters, well closed so as to exclude light and moisture; or they may be coarsely ground, and the well-dried powder preserved in well-stoppered and opaque bottles.

As foxglove deteriorates with age, it should be frequently renewed, as often, if possible, as once a year. Its quality must be judged of by the degree in which it possesses the characteristic properties of color, odor and especially taste. It is said to be sometimes adulterated, but if it is bought in leaf, there can be little difficulty, to one acquainted with the characters of the genuine leaves, in detecting the sophistication. German digitalis consists of the leaves of wild plants, whereas English digitalis is from cultivated plants. According to England, comparative experiments made in the Philadelphia Hospital have shown the English digitalis to be much more uniform and active than is the German drug. This may be because the English variety is more carefully freed from leafstalks, since Brooker found the parenchyma to yield five times as much digitalin as did the leafstalks. On account of our lack of chemico-physiological knowledge concerning the active principles of digitalis, and the obstacles which make physiological assay practically unreliable, the greatest difficulty exists in determining the exact medicinal value of samples of digitalis. Wholeness, fine physical appearance and freshness of the leaves, with freedom from petioles, afford the best foundation for judgment, even though they are not an absolute guarantee of superior activity. The percentage of digitoxin is not a correct measure of value, as has been shown by various investigators. It is important to

¹ *Digitalis ambigua* contains, according to Paschke, the same constituents as *D. purpurea* (*Ap. Ztg.*, 1888), while in therapeutic studies made in Sudentburg-Magdeburg Hospital the preparations of *D. grandiflora* were found to be at least as active as are those of the official plant. (*S. Jb.*, 271, p. 51.)

remember that not only does the digitalis leaf, but also such preparations as the tincture, deteriorate with keeping.¹

The seeds contain more of the active principle than the leaves, are less likely to suffer in drying, and keep better, but are little used. So far as the relative strength of these two parts can be determined from that of their alcoholic extracts, it would appear, from the experiments of Hirtz, that the seeds are ten times stronger than the leaves. (See *A. J. P.*, xxxiii.)

Properties.—Foxglove is without odor in the recent state, but acquires a faint narcotic odor when dried. The color of the dried leaf is a dull pale green, modified by the whitish down upon the under surface; that of the powder is a fine deep green. "Usually in more or less crumpled and broken fragments; ovate to oval, from 10 to 30 Cm. long, 5 to 15 Cm. broad, abruptly contracted into a winged petiole from 5 to 10 Cm. long; thin, dull and rather pale green or grayish underneath; upper surface wrinkled, sparsely hairy; lower surface densely and finely hairy, the venation conspicuously reticulated; margin crenate or erose-dentate; the midrib and principal veins broad and flat, usually purplish, the lower veins continued into the wings of the petiole; odor slight, characteristic; taste strongly bitter. In the powder, stone-cells, star-shaped hairs, and calcium oxalate crystals are absent." *U. S.* "The transverse section exhibits a mesophyll free from crystals of calcium oxalate." *Br.* Digitalis yields its virtues both to water and to alcohol. It contains, besides active principles, a volatile oil, a fatty matter, a red coloring substance analogous to extractive, chlorophyll, albumen, starch, sugar, gum, lignin, and salts of potassium and lime, among which, according to Rein and Haase, is acid potassium oxalate. Morin of Geneva, discovered in the leaves two acids: one fixed, called *digitalic acid*, the other volatile and resembling valerianic acid, which he proposed to name *antirrhinic acid* (*P. J.*, vii. 294). England (*A. J. P.*, 1892, 361) found about 5 per cent. of fixed oil in digitalis leaves. Morries obtained a narcotic empyreumatic oil by the destructive distillation of the leaves. The yield of ash from digitalis leaves is usually put down at from 7 to 10 per cent., and this is in accord with the result reached by F. H. Alcot with British leaves. (*P. J.*, Jan. 1903.) On the other hand, M. Greshoff (*P. J.*, Dec. 1902) has obtained in various samples of German digitalis, after the leaves have been freed from sand and the leaf-stalks removed, a yield of from 16.4 to 25 per cent. of ash.

Under the name of *digitalin*¹ there have long been in commerce two distinct substances obtained from digitalis, both of them crude mixtures of the glucosidal principles. The French digitalin was that originally prepared by Homolle. It is a whitish powder, of a neutral reaction, soluble in 2000 parts of cold and in 1000 parts of hot water. It is this digitalin which was formerly recognized by the *U. S.* and *Br. Pharmacopœias*. The so-called *German digitalin* is distinguished from the French by being, in great part or entirely, freely soluble in water.

In 1871, Nativelle received from the French Academy the prize of Orfila for the discovery of the active principle of digitalis. The method of preparation, as finally improved and modified by himself, and published in the *J. P. C.*, xx. 1874, p. 81, and also a process which has the advantage of being far shorter and more readily carried out, devised by Tanret (*Ibid.*, Oct. 1875), may be found on p. 1143, 14th ed., *U. S. D.*

According to the researches of Schmiedeberg (*P. J.* (3), v. 741), confirmed by Kiliani (*P. J.* (3), xxii. 1061, and (4), i. 29), the seeds and

¹ French digitalin may be prepared according to the following process, which was recommended by the British Pharmacopœia (1867):

"Take of Digitalis Leaf, in coarse powder, forty ounces [avoirdupois]; Rectified Spirit, Distilled Water, Acetic Acid, Purified Animal Charcoal, Solution of Ammonia, Tannic Acid, Oxide of Lead in fine powder, Pure Ether, of each, a sufficiency. Digest the Digitalis with a gallon [Imperial measure] of the Spirit for twenty-four hours at a temperature of 120°; then put them into a percolator, and when the tincture has ceased to drop, pour a gallon [Imp. meas.] of Spirit on the contents of the percolator, and allow it slowly to percolate through. Distill off the greater part of the Spirit from the tincture, and evaporate the remainder over a water-bath until the whole of the alcohol has been dissipated. Mix the residual extract with five [fluid] ounces of Distilled Water to which half an ounce [avoird.] of Acetic Acid has been previously added, and digest the solution thus formed with a quarter of an ounce of Purified Animal Charcoal; then filter, and dilute the filtrate with Distilled Water until it measures a pint [Imp. meas.]. Add Solution of Ammonia nearly to neutralization, and afterwards add one hundred and sixty grains of Tannic Acid dissolved in three [fluid] ounces of Distilled Water. Wash the precipitate that will be formed with a little Distilled Water; mix it with a small quantity of the Spirit and a quarter of an ounce of the Oxide of Lead, and rub them together in a mortar. Place the mixture in a flask, and add to it four [fluid] ounces of the Spirit; raise the temperature to 160°, and keep it at this heat for about an hour. Then add a quarter of an ounce of Purified Animal Charcoal; put it on a filter, and from the filtrate carefully drive off the Spirit by the heat of a water-bath. Lastly, wash the residue repeatedly with pure Ether." According to the method of Walz (Husemann, *Die Pflanzenstoffe*, p. 900), German digitalin is prepared by extracting under pressure one part of digitalis with eight parts of alcohol, evaporating, digesting the residue with successive portions of water so long as they acquire a bitter taste, uniting the liquids, and treating them with litharge and lead acetate until a portion filtered for testing is no longer precipitated by lead acetate. Sulphuric acid is added to the filtrate to precipitate the lead, and, after filtration, neutralized with ammonia, and the liquid precipitated by tannic acid. The precipitate having been well washed and pressed, is rubbed up with freshly precipitated lead oxide, the mass boiled with alcohol, and, after the lead has been separated by precipitation with sulphuric acid, and most of the alcohol distilled off, the residue is allowed to slowly evaporate, the crude digitalin being left behind.

¹ The research of H. Ziegenbein (*A. Pharm.*, Sept. 1902), made upon fourteen samples of wild and cultivated leaves from different localities, shows that the activity of digitalis varies very greatly, according to locality and probably also to the variety of the plant; that the unbroken leaves greatly deprecate on long keeping, and that the powdered leaves deprecate very rapidly; that the toxicity of digitoxin obtained from a given quantity of the dried leaves is from 2.6 to 6.6 less than that of the extract of the same leaves. (See *A. Pharm.*, Sept. 1902, also *P. J.*, Dec. 1902.)

leaves of *Digitalis purpurea* contain a preponderating amount of a glucoside, *digitonin*. They contain in addition three other substances which possess the power of acting on the heart, namely, crystallizable *digitoxin* and two amorphous glucosides, *digitalin* and *digitalin*.

DIGITONIN forms fully one-half of the mixed glucosides from the digitalis seed and the principal portion of German "digitalin," from which it may be prepared by extraction with and crystallization from 85 per cent. alcohol. Digitonin softens at 225° C. and melts completely at 235° C. The crystals dissolve sparingly in cold water, more readily in hot, to an opalescent solution which froths on agitation. It cannot be crystallized from water. The aqueous solution is lævo-rotatory ($[\alpha]_D = -49$ at 25° C.), and is precipitated by tannin, ammoniacal lead acetate, and baryta water. Digitonin is only slightly soluble in absolute alcohol, and still less so in ether, chloroform, or petroleum benzin. It forms a crystalline compound with amyl alcohol. According to Kiliani digitonin has the formula $C_{27}H_{46}O_{14} + 5H_2O$, and when boiled with strong alcohol and hydrochloric acid splits up into *dextrose*, *galactose*, and *digitogenin*, the last body separating in warty masses on cooling.

DIGITOXIN is characterized by its free solubility in alcohol and chloroform, slight solubility in ether, and insolubility in petroleum benzin. It crystallizes from alcohol in pearly scales or needles which melt at 240° C. It is quite insoluble in water, to which it does not impart even a bitter taste. Warmed with strong hydrochloric acid, it gives a yellow or greenish coloration, which is one of the reactions ascribed to the "digitaline crystallisée" of the French Codex. Schmiedeberg states that it is not a glucoside, but Kiliani asserts that upon heating its alcoholic solution with hydrochloric acid it splits up into *digitoxigenin* and a glucose *digitoxose*. The reaction for this is now considered to be:

Digitoxin is found mainly in the leaves (Kiliani stating that it is not found in the seeds at all), but Keller (*P. J.*, July 24, 1897) finds it also in the seeds in smaller amount. It is the most poisonous of the constituents of digitalis.

DIGITALIN (*Digitalinum verum* of Kiliani) forms a white amorphous powder or soft white grains which remain unchanged when heated to 200° C., at 210° C. begin to aggregate, and towards 217° C. melt, becoming yellow. When treated with water the particles of digitalin swell up and dissolve slightly, giving a solution which foams strongly on agitation. It is dissolved sparingly by cold proof spirit (1 to 100), but in considerable amount by hot rectified spirit or absolute alcohol. When a minimum of alcohol is used, the solution on cooling becomes almost solid from the separation of a thick magma of granules, which are, however, destitute of crystalline structure.

This peculiar behavior affords a valuable means of testing its purity, as only a small percentage of the other glucosides with the digitalin prevents the formation of the granules. The minutest admixture of amorphous glucosides also rapidly causes an intense yellow coloration. Digitalin is very sparingly soluble in ether or chloroform. When digitalin is heated with diluted hydrochloric acid, an insoluble resinous substance almost immediately separates out; Schmiedeberg termed this *digitaliresin*. By operating in alcoholic solution, Kiliani avoids the separation of resin, and finds that digitalin splits up as a glucoside into *digitoxigenin*, *glucose*, and *digitalose*, thus:

Kiliani found that commercial *digitalinum purum* contained but 5.5 per cent. of true digitalin.

DIGITALIN is considered to be a distinct glucoside by Schmiedeberg, but Kiliani, who worked over it later, regards its independent existence as questionable.

DIGITIN of Schmiedeberg is also considered by Kiliani to be simply digitonin.

The above résumé of our present knowledge clearly shows that the chemistry of digitalis cannot be considered as settled; but it also clearly shows that no digitalin completely represents digitalis. Moreover, the digitalin of commerce varies greatly. (See *A. Pharm.*, 1895, 299; also 1895, 698.)

No satisfactory assay process has yet been devised for digitalis and hence the U. S. P. (8th Rev.) contains no process. The amount of digitoxin present in digitalis has been proposed by several investigators as a means of standardizing it, but it is by no means clear that this would prove a reliable criterion (*Ber. d. Chem. Ges.*, 1897; *Pharm. Rev.*, 1901, 514; *D. C.*, 1902, 223; *P. J.*, 1902, 663; *Chem. News*, 1903, 123; *A. Pharm.*, 1903, 358). Physiological tests have also been proposed by Moschkowitsch, Focke and others based upon the action of digitalis preparations upon the hearts of frogs, but the experiments of Moschkowitsch point out that the individuality, age, weight, sex, species, source (habitat), of the frogs and the time of the year that the frogs are used, materially affect the value of the test. The physiological assay of digitalis is, however, used by manufacturers as a comparative test of value. J. Gordon Sharp proposed a test for digitalis based upon the fact that the leaves contain an enzyme, which acts on amygdalin producing an odor like that of bitter almond with hydrocyanic acid. (*P. J.*, 1902, 236.)

Uses.—Experiments upon the lower animals, confirmed by clinical observation, have shown that digitalis acts primarily and with most force upon the circulation, producing a great rise in the arterial pressure. The increased blood force is due partly to increased cardiac action and partly to vasomotor spasm. Upon the heart digitalis acts by stimulating the pe-

ripheral ends of the inhibitory nerves and also the cardiac muscle. By the first influence it produces prolongation of the diastole; by the second, an increased putting forth of power in the systole. The work done by the heart under the influence of the drug is much beyond normal. After a toxic dose the systolic irritation overbalances the diastolic stimulation, and the pulse becomes dicrotic, because the diastole is aborted by an interrupting systole. Finally, the apex of the heart never dilates, diastole is continually interrupted by systolic contractions, and the aortic system remains empty, because the left ventricle never relaxes sufficiently to receive blood. In the frog at least the final cessation of the heart's action is not due to paralysis, but to spasm, the heart ceasing not in diastole, but in systole; the warm blooded heart, however, seems incapable of continuous spasm and usually relaxes completely immediately before death.

This résumé of our knowledge of the physiological action clearly indicates the proper use of the drug. It is indicated when the heart is weak,—not absolutely, but relatively weak, or, in other words, when the work required of the heart is greater than its power. When digitalis is administered in ordinary doses, it produces at first no distinct effect; but if the dose be repeated, after a time the pulse becomes less frequent. The pauses between the beats are longer than before, and the individual beat is longer, fuller, and stronger, indicating that the heart is acting with more force than normal. When the reduction of the pulse rate has commenced, it is likely to continue for some days, and even to increase for a time, although the use of the remedy be intermitted, slowness and permanency of action being characteristic of digitalis. In some cases, gastric disturbances, and even nausea, vomiting, and diarrhoea, are produced by the therapeutic doses of the drug. If sufficient of the remedy has been taken into the system, the pulse may fall to 35 or 40 a minute, still preserving the peculiarity of a distinctly dicrotic beat. Now a very peculiar phenomenon may often be witnessed. While the patient is quiet in the horizontal position the pulse is very slow and strong, but when he rises to his feet it becomes at once rapid, irregular, small, and feeble, and even hobbling. During the milder operation of digitalis there may be some sense of cerebral disturbance, brow-tightness, and even a confusion of thought and giddiness. After toxic doses the symptoms are severe; a feeble, scarcely perceptible pulse, nausea and vomiting, stupor or delirium, cold sweats, extreme prostration of strength, hiccough, convulsions, and syncope have in several cases preceded the fatal issue.

The dilated heart is of course a weak heart, and simple *cardiac dilatation* is one of the strongest indications for the use of digitalis, while cardiac hypertrophy is a contra-indication. It must not be forgotten, however,

that in *valvular disease*, the heart, although stronger than normal, may be relatively weak, because the leakage at the diseased valve requires more power to overcome its effect than even the increased strength of the cardiac muscle is able to give. Hypertrophy exists, but is not sufficient to be compensatory. In all forms of valvular lesion, when the hypertrophy is not compensatory, digitalis is very useful. It is also to be employed (hypodermically) in sudden cardiac exhaustion from any cause. *Dropsy* is very frequently the result of a general venous repletion, which also interferes with the function of the kidneys. Under these circumstances digitalis is a favorite remedy, and also acts as a decided diuretic. In these cases the result is in greater or less part due to the improvement of the circulation, but the drug has some tendency, even in health, to provoke diuresis. It is especially when it fails to do this that the so-called cumulative action is likely to be witnessed. After giving the drug for a long time without apparent effect, suddenly symptoms so severe as to be toxic are manifested. In aneurism, or when from any reason the coats of the vessels are thin or fragile, digitalis is contra-indicated. We have seen a dilated aorta ruptured by the powerful blood-current produced by the drug.

Externally applied, digitalis sometimes acts speedily and powerfully as a diuretic, and has proved useful in dropsy. For this purpose the fresh leaves bruised, or the dried leaves made into a poultice, or flannels wet with the tincture, may be applied to the abdomen and on the inside of the thighs. Ch. Hoffman has shown by experiments on himself that the active matter of digitalis is capable of being absorbed through the skin, and that its effects on the system may be obtained by means of baths.¹ A case is recorded in which a cataplasm of the leaves applied to the abdomen for the relief of obstinate and dangerous suppression of urine, and repeated in six hours, brought on excessive diuresis, with a discharge amounting to probably 8 gallons in less than 24 hours, producing fatal exhaustion. (*M. T. G.*, Jan. 1868.)

Digitalis is administered in substance. The dose of the powder is one grain (0.065 Gm.), repeated twice or three times a day, and gradually increased until some effect is produced upon the head, stomach, pulse, or kidneys, when it should be omitted or reduced. The question as to which of the preparations of digitalis is preferable is a very important one. All the active principles are soluble in alcohol; the tincture (*Tinctura Digitalis*), therefore,

¹ Hoffman, during a period of 44 days, took 16 baths prepared with 300 liters of water and 250 grammes of digitalis leaves. After the third bath he began to feel the effects of the medicine,—namely, a peculiar uneasiness, and a reduction of the pulse 4 or 5 pulsations per minute; and this condition persisted several hours. At the eighth bath the uneasiness was increased, and the pulse decreased from 68 to 51. After the sixteenth bath the pulse fell to 48. (*J. P. O.*, Juillet, 1867, p. 37.)

fully represents the crude drug. According to Kobert, in the making of the fluidextract digitoxin is precipitated as an insoluble powder. If this is correct, the fluidextract does not as fully represent the crude drug as does the tincture. It is, however, very possible, indeed probable, that digitoxin should be precipitated in one method of making a fluidextract and not in another, so that it cannot be considered demonstrated that the U. S. P. fluidextract, contains no digitoxin. As digitoxin is not soluble in water, it would seem, *a priori*, probable that it and the other constituents of the so-called French or insoluble digitalin would be left behind in making an infusion, but certainly the infusion of digitalis is an active preparation and is preferred by many practitioners. It is possible that the superiority claimed by some clinicians for the infusion, which we have elsewhere otherwise explained (see page 655), is in fact due to the absence from it of active substances which are present both in the crude digitalis and in the tincture. A careful chemical physiological investigation of the relative activities of the preparations of digitalis seems to us urgently needed, but the probabilities are that all the official preparations are active when they have been carefully made from well selected leaves.

The subject of the therapeutic activity and value of the different non-official preparations of digitalis is one of great difficulty, and at present of doubt. In these paragraphs we propose to consider only the commercial products or educts of digitalis which are for sale in the market. These commercial preparations are of two characters, the so-called digitalins—which should be looked upon either as purified extracts of digitalis or crude glucosidal products.

As already stated (p. 425), there are two digitalins; of these *Digitalinum gallicum*, or French digitalin, official in the French and Belgian Pharmacopœias, is almost insoluble in water, and is said to consist largely of a glucoside allied to digitoxin. (See *P. J.*, 1898, 506.) The dose of the commercial article is put down at one two hundred and sixtieth of a grain (0.00025 Gm.), rapidly increased to one-fortieth of a grain (0.0016 Gm.) per day, the maximum daily dose being one-thirtieth of a grain (0.002 Gm.). The granules of Homolle, which were formerly used in Europe, each contained a milligramme, or about the seven-tieth of a grain, probably equivalent, on the average, to a grain and a half of digitalis of medium strength. One of these globules is usually given as a commencing dose. Forty of them taken with a view to suicide, though followed by copious vomiting, produced the most alarming prostration, with a weak pulse, from 46 to 48 in a minute, intermittent, and at times scarcely perceptible. The patient, however, ultimately recovered. (*Ann. Thé.*, 1858, 103.)

Digitalinum germanicum, digitalin of the German Pharmacopœia, is soluble in water and alcohol but almost insoluble in chloroform; it is believed to be a mixture of digitalein, crystallized digitalin, digitonin, and digitalin of Kiliani. It formerly was employed quite largely, but fell into desuetude probably on account of its having habitually been given in too small doses, as insisted upon by Henry Beates. The dose was formerly considered to be one-fiftieth to one-thirtieth of a grain (0.0013 to 0.002 Gm.), but according to the clinical reports of Beates, and the experiments of Arnold and Wood, Jr., one-fourth of a grain (0.016 Gm.) is about equivalent to 15 minims of the tincture of digitalis, so that it may be given with safety in doses of one-eighth to one-fourth of a grain. This conclusion is in accord with the statement to us of Merck & Co. that in the manufacture of German digitalin the average yield is from 4 to 5 per cent. On this basis, if German digitalin did nearly represent digitalis, it would be from twenty to twenty-five times as strong, so that four-tenths of a grain of it would stand for eight grains of digitalis, or about eighty minims of the tincture. Except for the convenience of administration, German digitalin has no superiority, however, over the older preparations. Much of it upon the market is probably badly made. As a hypodermic agent we have found it as irritant as is the tincture of digitalis. Physiological tests made by Lyons and Famuliner upon frogs showed that Merck's digitalin, which was found to be very uniform in strength, was nearly 30 times as strong as a sample of digitalis of average quality. (*Proc. A. Ph. A.*, 1902, 424.)

Digitalinum crystallizatum or *digitin* is commonly affirmed to be physiologically inactive, though Laffron asserts that it is as powerful as digitoxin.

Digitonin is asserted by authorities to be similar in its physiological action to saponin, which has, on the other hand, apparently been demonstrated to be the physiological antagonist of digitalis. It is evident, therefore, that digitonin, so far as our present knowledge is concerned, cannot be used as the representative of digitalis.

Of *digitalein*, it is asserted that when given in doses of from one-sixty-fourth to one-thirtieth of a grain (0.001 to 0.002 Gm.), two to four times a day, it acts as a heart tonic and diuretic similarly to digitalis. According to Merck & Co., the average yield of digitalein is 1 per cent., which would make the dose contained in one grain of digitalis the one-hundredth of a grain (0.0006 Gm.). It, however, represents such a small fraction of the activities of digitalis that a much larger dose would seem to be required. In this case the dose given by authorities evidently is below that which by calculation would appear to be safe. It is not probable, however, that digitalein nearly represents digitalis.

Digitoxin has been proven by the experiments of J. P. Arnold and H. C. Wood, Jr., of Zeltner, and of Cushny, to affect the circulation of the lower animals as does *digitalis*, and it has been recommended as acting more quickly and favorably in cardiac diseases than do the older preparations of *digitalis*, by Potain, Potteiz, Starek, Masius, Corin, and other clinicians. That it is an efficient drug is established, but that it has distinct advantages is not apparent. It is locally very irritant and probably at least as prone as is *digitalis* to derange the digestion. Its tendency to cumulative action, so marked in the experiments of Frankel, has been confirmed in those of Arnold and H. C. Wood, Jr., and clinically by Zeltner. Moreover, the general verdict is that it acts more slowly than does *digitalis*. When given in solution it is probably precipitated in the alimentary canal and absorbed with great slowness. It is so insoluble in neutral menstrua, and so irritant, that it is unfit for hypodermic use.¹

Further, there is much uncertainty as yet as to its strength compared with *digitalis*. *Digitoxin* is, however, according to Zeltner one thousand times, according to Bosse fifteen hundred times, more active than *digitalis*; while Curioni gives as the minimum ordinary single dose the one-hundred and twentieth of a grain, the maximum dose one-sixtieth of a grain. In our opinion the commencing dose in any case should not exceed the two-hundred and fortieth of a grain (0.00025 Gm.).

Dose, of *digitalis* leaves, one to two grains (0.065 to 0.13 Gm.).

¹ *Hypodermic solution of digitoxin.*—Corin affirms (*Nouv. Rem.*, 1895, 200) that the addition of water, or physiological fluid, or serum, while it will precipitate alcoholic solutions of 20 per cent. strength of *digitoxin*, will not affect a solution made in accordance with the following formula: *Digitoxin*, 2 to 3 milligrammes; *Chloroform*, 0.6 Cc.; *Alcohol* (90 per cent.), 12 Cc.; *Water*, a sufficient quantity to make 150 Gm. To be taken in three doses.

Madsen of Copenhagen, states that one cubic centimeter (16 minims) of so-called *Pettit's solution* will dissolve one milligramme (one sixty-fourth of a grain) of *digitoxin*; and that four minims of this solution (one two hundred and fortieth of a

Rubber was made official in the U. S. P. 1890 because of its use in making mustard paper.

The widespread destruction of the native rubber trees, especially in the valley of the Amazon, with other causes, slowly led to experiments in the cultivation of the plants. The first important trials were made in Assam in 1860, since which time, especially under the fostering care of the British Government, much has been accomplished. The attempts, however, to acclimatize the *Castilloa elastica* and the *Hevea brasiliensis* in Ceylon and India finally failed. More successful were the plantations of the *Manihot Glaziovii*, which has been found to thrive well at an altitude of about 6000 feet in Ceylon, and also in India, and which bids fair to be the great india-rubber tree of the future, especially in view of the fact that cultivation was stimulated by the rapid disappearance of the wild *Landolphias* in the French Congo; government experiments have proven that the *Manihot* grows well in that region.

In Brazil, india-rubber is procured from the trees by making vertical cuts with a narrow-bladed hatchet, in the bark, in the period between the end of August and the first of January, and collecting the latex as it falls, drop by drop, often to the amount of more than one fluidounce from each incision. Generally in Central and South America, as well as in Africa and Asia, the method of tapping the trees is similar, though the period of year at which the best yield of latex is obtained varies. The old method of obtaining rubber, by the cutting down of the tree, is probably no longer followed, except in Congo (Free) State. When collected the latex is caused to coagulate, usually by the use of heat, dry or moist, artificial or natural. The Para rubber owes its peculiar physical character to the fact that the coagulation of the latex is produced by smoking it. In Africa, and to some extent in America, coagulation is effected by the addition of certain chemicals, notably alum, sulphuric acid, common salt, soap, and citric acid.

The importance of india-rubber in the arts is evinced by the fact that in the fiscal year ending June, 1904, 59,015,551 pounds, valued at \$40,444,250, were brought into the United States. Of this amount 33,109,112 pounds came directly from Brazil, while 21,000,000 pounds reached the United States through Europe.

India-rubber or caoutchouc is a hydrocarbon obtained from the milky juice of certain tropical plants. This milky juice is contained chiefly in the so-called laticiferous vessels, situated in the internal zone of the bark, which are composed of isolated cells, so arranged as to form large vessels with many ramifications. A hydrocarbon is formed by the protoplasm of the cells which belong to the fundamental parenchymatous structure of the

grain) is the hypodermic dose. *Pettit's solution*, glycerin 333 parts, alcohol 95 parts, water to 1000 parts.

bark and not to the fibro-vascular bundles. That the hydrocarbon is a waste product, incapable of use in the economy of the plant, is believed by some naturalists; that it is necessary to the life of the plant, as believed by other naturalists, is not yet proved, the probabilities, however, are in favor of the latter view.

The latex as it first exudes from the wounded plant is said to have some resemblance to the milk of the goat, containing suspended microscopic granules which are affirmed by Adriani to have a diameter of not more than two or three micromillimeters. In its best forms the yield of pure india-rubber from the latex or milk juice, should be as much as 32 per cent.

Although various milky-juice plants of the temperate countries contain the hydrocarbon, india-rubber is a product only of the tropical and sub-tropical countries. It is said to be obtained for commercial purposes from at least 90 species of plants, representing five different botanical families, namely:—the Euphorbiaceæ, Artocarpaceæ, Moraceæ, Apocynaceæ, and Aselepiadaceæ.

The india-rubber producing Euphorbiaceæ are chiefly South American trees, inhabiting the region from extreme Southern Brazil to Northern Venezuela. The most important of these belong to the genus *Hevea*. The *Hevea brasiliensis* (*Siphonia brasiliensis*) yields the most esteemed commercial rubber. The *Hevea guianensis* has been acclimatized and is cultivated in Ceylon, British India, and other parts of Southern Asia. In the Gaboon Coasts, Congo, and Ceylon, the *Manihot Glaziovii* has been cultivated.

The india-rubber producing Moraceæ have a very wide distribution throughout tropical countries. Of the South American species the most important is the *Castilloa elastica*, a large tree which inhabits Mexico, Central America, Northern South America, and the West Indies, and formerly produced the bulk of the india-rubber of Mexico and Central America. In Asia and Africa the most important india-rubber Moraceæ belong to the genus *Ficus*; the chief species being the *Ficus indica*, L., of Southern Asia and the Philippine Islands, familiarly known as the *Banyan tree*; and the *Ficus elastica*, Roxb., of India and Java, known as the *india-rubber plant* of our hot-houses.

Belonging to the Apocynaceæ are numerous *bind-weeds*, natives of Africa, Asia, and various parts of Oceania. The most important of these belong to the genus *Landolphia*, large woody bind-weeds which grow over the trees of Liberia, Gaboon, Angola, Zanzibar, Madagascar, and other portions of Africa, reaching a length of 80 feet, and a trunkal diameter of 6 inches, covering large masses of ground and making forests almost impassible. From them comes the bulk of African rubber. The apocynaceous genus *Vahea* is represented in both South America, Eastern, Western and Central Africa;

while the genus *Willoughbeia* grows in Southern Asia, and has been acclimatized in Australia.

Properties.—Rubber occurs in large flat pieces, or moulded into various shapes. The latter are formed by applying successive layers of the juice upon moulds of clay, which are broken and removed when the coating has attained a sufficient thickness and consistence. In the drying of these layers they are exposed to smoke, which gives to the concrete mass a blackish color. Rubber is officially described as "in flask-shaped or roundish masses, or in pieces of the same having sharply incised surfaces and exhibiting a laminated structure; floating on water; externally brownish to brownish-black; internally of a lighter tint, mottled; odor creosote-like; nearly tasteless. Pure Para Rubber is insoluble in water, dilute acids, or dilute solutions of the alkalis; soluble in chloroform, carbon disulphide, oil of turpentine, petroleum benzin, and benzene; when heated to about 125° C. (257° F.) it melts, remaining soft and adhesive after cooling." U. S. "In elastic masses of varying thickness, brownish black externally and mottled with a pale tint internally; insoluble in water, ethylic alcohol, alkaline solutions, or dilute acids, soluble in chloroform, oil of turpentine, carbon bisulphide, benzol, and petroleum spirit. When heated to about 257° F. (125° C.) it melts, remaining soft and adhesive after cooling. Odor characteristic, somewhat empyreumatic; nearly tasteless." Br.

Chemical Constitution.—The juice of the rubber trees, when it concretes by exposure to the air, assumes on the outer surface a yellowish-brown color, while the mass remains white or yellowish-white within. It is said that a little alum facilitates the coagulation, while ammonia retards it, so that a little of the latter may be advantageously added, when it is desired to keep the milky juice in the liquid state. (R. Spruce, *P. J.*, xv. 118.) The recent juice contains, according to Faraday, 1.9 per cent. of vegetable albumen, traces of wax, 7.13 per cent. of a bitter nitrogenous substance soluble in water and alcohol, 2.9 of a substance soluble in water but insoluble in alcohol, 56.37 soluble in water with a little free acid, and only 31.7 of the pure elastic principle to which chemists have given the name of caoutchouc. Besides these principles, the concrete juice, as it reaches us, generally contains soot, derived from the smoke used in drying it. *Pure caoutchouc*, or rubber, is nearly colorless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and odor, fusible at about 120° C. (248° F.), remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in chloroform and most of the fixed and volatile oils, though, in the latter, at the expense of its elasticity. It

is said, however, that the oils of lavender and sassafras dissolve it without change, and that when precipitated by alcohol from its solution in oil of cajuput it is still elastic. But its best solvents, for practical purposes, are coal naphtha or petroleum benzin, the empyreumatic oil obtained by distilling caoutchouc itself, and pure oil of turpentine. According to Bolley, the best method of effecting its solution, for the preparation of a varnish, is first to digest it, cut in small pieces, in carbon disulphide, which converts it into a jelly, and then to treat this jelly with petroleum benzin. A larger proportion is thus taken up than by any other method. Rubber is not affected by atmospheric air, chlorine, hydrochloric or sulphurous acid gas, or ammonia. Rubber chemically is composed of a mixture of polyterpenes. When destructively distilled, it yields *isoprene*, C_5H_8 , and *dipentene*, $C_{10}H_{16}$. When isoprene is treated with concentrated hydrochloric acid, it is polymerized, and a substance obtained which resembles caoutchouc and is probably identical with it. When rubber is vulcanized, it may contain from 2 to 20 per cent. of sulphur, of which, however, not more than the lower amount is chemically combined, the rest being held mechanically, and capable of removal by treatment with caustic alkalies.¹ Bouchardat succeeded in preparing from isoprene an artificial caoutchouc by acting upon the isoprene with saturated hydrochloric acid in sealed tubes.

Uses.—Rubber is so insoluble that it cannot be absorbed in any form into the blood. It is used enormously in the arts for an infinite variety of purposes. In chemistry and surgery it has also numerous applications.

¹ By the action of sulphur, rubber acquires properties which greatly increase its value in the arts. It either becomes pliable, soft, and tough, or if the amount of sulphur be increased, of a horny consistency, but preserves its elasticity under the influence both of heat and cold, is compressible with great difficulty, and resists the ordinary solvents such as petroleum and oil of turpentine. In this state it is said to be *vulcanized*. The discovery of the process of vulcanization is ascribed to Charles Goodyear of New York. (*Chem. Gaz.*, x. 193.) It consists in submitting rubber in thin sheets to the action of a mixture composed of 40 parts of carbon disulphide and 1 of sulphur chloride. For fuller details the reader is referred to the *J. P. O.* (3e sér., xvii. 205.) The same object may be effected by other methods. When thin layers of rubber are immersed for two or three hours in melted sulphur at the heat of $116^{\circ} C.$ ($240^{\circ} F.$), they are penetrated by the sulphur, but undergo no change of properties. If now heated in an inert medium to a temperature of now heated from $135^{\circ} C.$ ($275^{\circ} F.$) to $160^{\circ} C.$ ($320^{\circ} F.$), a chemical reaction takes place, and the vulcanized product is obtained. The same result takes place if the rubber be first pounded with from 12 to 20 per cent. of finely powdered sulphur, and then heated to the temperature requisite for vulcanization. In either case a portion of uncombined sulphur remains mechanically mixed with the vulcanized rubber, from which it may be separated by various solvents, such as solutions of potassium or sodium hydroxide, carbon disulphide, oil of turpentine, anhydrous ether, etc. The *desulphurated* product thus obtained, while exempt from the disadvantages arising from the reaction of free sulphur, is more porous than before. (*Ibid.*, xxi. 366.) For details of these two processes,—viz., vulcanization by heat with sulphur or metallic sulphides, and cold vulcanization with solutions of sulphur chloride,—see Sadtler's *Industrial Organic Chemistry*, pp. 99–101.

ELATERINUM. U. S., *Br.*

ELATERIN

(*ël-à-tê-rî-nûm*)

“A neutral principle obtained from elaterium, a substance deposited by the juice of the fruit of *Ecballium Elaterium* (Linné) A. Richard (Fam. *Cucurbitaceæ*).” U. S. “Elaterin, $C_{20}H_{28}O_5$, is the active principle of Elaterium.” *Br.*

Elaterine, *Elatine*, *Fr.*; Elaterin, *G.*; Elaterina, *Sp.*

Preparation.—Elaterin was introduced into the Pharmacopœias on account of the well-known variability in quality of commercial elaterium. (See *Elaterium* and *Trituratio Elaterini*.) Care must be taken to examine the elaterin, which is itself liable to be adulterated. It may be procured by evaporating an alcoholic tincture of elaterium to the consistence of thin oil, and throwing the residue while yet warm into a weak boiling solution of potassium hydroxide, this holds the green resin in solution, and the elaterin crystallizes as the liquor cools. Hennell obtained it by treating with ether the alcoholic extract procured by the spontaneous evaporation of the tincture. This consists of elaterin and the green resin, the latter of which, being much more soluble in ether than the former, is completely extracted by this fluid, leaving the elaterin pure. But, as elaterin is also slightly soluble in ether, a portion of this principle is wasted by Hennell's method. By evaporating the ethereal solution, the green resin is obtained separate. Hennell says that this was found to possess the purgative property of elaterium, as it acted powerfully in a dose less than one-third of a grain. But the effect was probably owing to the presence of a portion of elaterin which had been dissolved by the ether. Flückiger prefers to exhaust elaterium with chloroform, and add to the percolate ether, which precipitates elaterin. The precipitate may be dissolved in chloroform and recrystallized. This process was adopted by the *Br. Pharm.* 1885.

Properties.—It is in “minute, white, hexagonal scales or prismatic crystals; without odor, and having a slightly acrid, bitter taste; permanent in the air, and containing no water of crystallization. Insoluble in water; soluble in 262 parts of alcohol, 318 parts of ether, 22 parts of chloroform, 272 parts of benzene, and 200 parts of amyl alcohol at $25^{\circ} C.$ ($77^{\circ} F.$); soluble in 75 parts of alcohol at $60^{\circ} C.$ ($140^{\circ} F.$). When heated to $190^{\circ} C.$ ($374^{\circ} F.$) it turns yellow, and at $216^{\circ} C.$ ($420.8^{\circ} F.$) it melts, forming a yellowish-brown liquid. On ignition, it is consumed without leaving any

residue. Its solutions are neutral to litmus paper. Sulphuric acid colors it yellow, the color changing gradually to scarlet. Sulphuric acid containing a trace of ammonium vanadate produces a blue color, changing to green and then to brown. Sulphuric acid containing a drop of formaldehyde gives a brown color. Sulphuric acid containing a trace of potassium dichromate produces an olive-green color, gradually turning darker. If a crystal of Elaterin be added to a little hydrochloric acid, and this evaporated to dryness, the residue washed with hot water, and afterwards treated with sulphuric acid, a brownish-red (amaranth) color will be produced. An alcoholic solution of Elaterin should not be precipitated by tannic acid T.S., mercuric chloride T.S., or platinic chloride T.S. (absence of, and difference from *alkaloids*)." U. S. "With melted phenol it yields a solution which, on the addition of sulphuric acid, acquires a crimson color, rapidly changing to scarlet." Br. Ernst Johannson (*In. Dis.*, Dorpat, 1884) gives the following reactions for elaterin besides those mentioned in the Pharmacopœia. In all of them elaterin is held in alcoholic solution. Froehde's reagent gives a green color passing into brown which fades away. Vanadinsulphuric acid with the fortieth of a milligramme produced a splendid blue color passing into a clear green, finally into reddish brown. After mixing with selenic acid and an addition of sulphuric acid, in a few minutes a red-brown color develops, which is not so deep as that which is produced by sulphuric acid. Kohler's reaction is produced by dissolving elaterin in a few drops of concentrated hydrochloric acid, evaporating the acid in a water bath, washing the white, amorphous residue with boiling water, and adding some concentrated sulphuric acid, when an amaranth-red color develops. By means of these reactions Johannson has been able to find elaterin in large quantities in the fæces of animals poisoned by it, but no trace in the blood or urine or any part of the organism.

Morries, obtained 26 per cent. from the best British elaterium, 15 per cent. from the worst, and only 5 or 6 per cent. from the French, while a portion procured according to the directions of the London College yielded to Hennell upwards of 40 per cent. The Br. Pharmacopœia directs that the proportion of elaterin should not be less than 20 per cent. Experiments by John Williams satisfactorily prove that the fruit, exhausted of the free juice from which elaterium is obtained, contains very little if any elaterin, certainly not enough to compensate for the cost of its extraction. (*Chem. News*, 1860, p. 124.)

Uses.—Elaterin represents all the activities of elaterium; to which it is preferable on account of the greater uniformity of its effects.

Dose, one-twentieth to one-tenth of a grain (0.003 to 0.006 Gm.).

ELATERIUM. Br.

ELATERIUM

(ē-l-ā-tēr'ī-ŭm)

"A sediment from the juice of the fruit of *Ecballium Elaterium*, A. Richard." Br.

Extractum Elaterii; Elaterium, Elaterion, Fr.; Elaterium, G.; Elaterio, It., Sp.

Ecballium Elaterium (L.), A. Rich.—*Momordica Elaterium*, Willd., *Sp. Plant.* iv. 605; Woodv., *Med. Bot.*, 192, t. 72.—*Ecballium agreste*, Richard; Lindley, *Med. and Econ. Bot.*, 95.—*Ecballium officinale*, Nees.—The wild or squirting cucumber is a perennial plant, with a large fleshy root, from which rise several round, thick, rough stems, branching and trailing like the common cucumber, but without tendrils. The leaves are petiolate, large, rough, irregularly cordate, and of a grayish-green color. The flowers are yellow, and proceed from the axils of the leaves. The fruit has the shape of a small oval cucumber, about an inch and a half long, an inch thick, of a greenish or grayish color, and covered with stiff hairs or prickles. When fully ripe, it separates from the peduncle, and throws out its juice and seeds with considerable force through an opening at the base, where it was attached to the footstalk. The name of squirting cucumber was derived from this circumstance, and the scientific and official title is supposed to have had a similar origin, though some authors maintain that the term *elaterium* was applied to the drug rather from the mode of its operation upon the bowels than from the projectile property of the fruit.¹

Preparation.—This species of *Ecballium* is a native of the south of Europe, and is cultivated in Great Britain, where, however, it perishes in the winter. Elaterium is the substance spontaneously deposited by the juice of the fruit, when separated and allowed to stand. From the experiments of Clutterbuck, it has been supposed that only the free juice about the seeds, which is obtained without expression, affords the product. The substance of the fruit itself, the seeds, as well as other parts of the plant, have been thought to be nearly or quite inert. From the statements made by Bell (see note, next page), these opinions must probably be somewhat modified; but there is no doubt that strong expression injures the product. When the fruit is sliced and placed upon a sieve, a perfectly limpid and colorless juice flows out, which soon becomes turbid, and in the course of a few hours begins to deposit a sediment. This, when collected and carefully dried, is very light and pulverulent, of a yellowish-white color, slightly tinged with green. It is the genuine elaterium, and was found by Clutterbuck to purge violently in the dose of

¹ From the Greek *ἑλαιο*, I drive, or *ἑλαιο*, driver. The word *elaterium* was used by Hippocrates to signify any active purge. Dioscorides applied it to the medicine of which we are treating.

one-eighth of a grain. But the quantity contained in the fruit is very small. Clutterbuck obtained only six grains from forty cucumbers. Commercial elaterium is often a weaker medicine, owing in part, perhaps, to adulteration, but much more to the mode in which it is prepared. In order to increase the product, the juice of the fruit is often expressed with great force, and there is reason to believe that it is sometimes evaporated so as to form an extract, instead of being allowed to deposit the active matter. The French elaterium is prepared by expressing the juice, clarifying it by rest and filtration, and then evaporating to a suitable consistence. As the liquid remaining after the deposition of the sediment is comparatively inert, it will be perceived that the preparation of the French Codex must be relatively feeble. The following are the directions of the British Pharm. (1885): "Cut the fruit lengthwise, and lightly press out the juice. Strain it through a hair sieve, and set aside to deposit. Carefully pour off the supernatant liquor; pour the sediment on a linen filter, and dry it on porous tiles, in a warm place. The decanted fluid may deposit a second portion of sediment, which can be dried in the same way." The latter portion deposited is of a lighter color. (Pereira.) The slight pressure directed is necessary for the separation of the juice from the somewhat immature fruit employed. The perfectly ripe fruit is not used, as, in consequence of its disposition to part with its contents, it cannot be carried to market. In the British Pharmacopœia, the former name of *Extractum Elaterii* of the London College has been very properly abandoned, as the preparation is in no correct sense of the word an extract. Elaterium is brought chiefly from England, but it is probable that a portion of the elaterium of which Pereira speaks as coming from Malta reaches our market also.¹

¹The following notice of the cultivation of the elaterium plant and the preparation of the drug at Mitcham, in Surrey, England, condensed from a paper by Jacob Bell in the *P. J.*, for October, 1850, may have some interest for the American reader. The seeds are sown in March, and the seedlings planted in June. In luxuriant plants the stem sometimes acquires an extraordinary breadth. In one instance, though not thicker than the forefinger where it issued from the earth, it was in its broadest part four inches wide and half an inch thick. A wet season interferes with the productiveness of the plant. At the spontaneous separation of the fruit, it throws out its juice sometimes to the distance of twenty yards; and hazard of injury to the eyes is incurred by walking among the plants at their period of maturity. A bushel of the fruit weighs 40 pounds, and the price varies from 7 to 10 shillings sterling. In the manufacture of elaterium, which begins early in September, the fruit, having been washed, if necessary, to cleanse it from earthy matters, is sliced longitudinally into halves, and then submitted to expression, wrapped in a hempen cloth, in a common screw press. Considerable force is used in the expression. The juice is then strained through hair, cypress, or wire sieves, and set aside for deposition. The deposit usually takes place in three or four hours. When this part of the process is completed, the supernatant liquor is carefully poured off, the deposit is placed on calico cloths resting on hair sieves, and allowed to drain for about twelve hours, after which it is removed by a knife, spread over small cloths, and dried on canvas frames in the drying-stove. About half an ounce of fine elaterium is obtained from a bushel of

Properties.—The best elaterium is in thin flat or slightly curled cakes or fragments, often bearing the impression of the muslin upon which it was dried, of a greenish-gray color becoming yellowish by exposure, of a feeble odor, and a bitter, somewhat acrid taste. It is pulverulent and inflammable, and so light that it floats when thrown upon water. When of inferior quality, it is sometimes dark-colored, much curled, and rather hard, breaking with difficulty, or presenting a resinous fracture. "In light, friable, flat or slightly curved, opaque cakes, about one-tenth of an inch (two and a half millimetres) thick; pale green, grayish green, or yellowish gray in color; fracture finely granular; odor faint, tea-like; taste bitter and acrid. It should not give the characteristic reactions with the tests for carbonates or for starch, and should yield half its weight to boiling alcohol (90 per cent.). When exhausted with chloroform, the solution evaporated, the residue washed with ether, and the process of solution, evaporation, and washing repeated, Elaterium should yield 25 per cent., or not less than 20 per cent., of Elaterin." *Br.*² The Maltese elaterium is in larger pieces, of a pale color, sometimes without the least tinge of green, destitute of odor, soft, and friable, and not infrequently gives evidence of having been mixed with chalk or starch. It sinks in water, and usually contains so little elaterin that it should be employed only as a source of that principle. In the analyses of T. A. Elwood,

fruit. Some obtain more, but the product is inferior, in consequence of the use of too much force in the expression. Good elaterium has a pale pea-green tint; that of inferior quality is of a duller hue. The juice expelled in bursting is said to undergo very little change in the air, while that expressed from the ripe fruit immediately afterwards becomes milky, and deposits elaterium. The recently burst fruit, therefore, is nearly if not quite as good for the preparation of the drug as that collected before perfect maturity. For a paper on the cultivation of the elaterium plant at Hitchin, Herts, England, see *A. J. P.*, 1860, p. 163; at Market Deeping, *P. J.*, Sept. 1881, p. 239.

²H. W. Jones and F. Ransom detail an improved method of assaying elaterium in the *Year-Book of Pharmacy*, 1886, p. 442; it is as follows: "Macerate 1 gramme of finely powdered elaterium with chloroform in a covered dish for a few hours, then transfer to a miniature glass percolator (e.g., the barrel of a small glass syringe) plugged with cotton, and wash with chloroform, allowing about 10 Cc. to pass through the marc after the menstruum has begun to pass in a colorless condition. Place the percolate in a small dish, and evaporate off the chloroform at a gentle heat. Treat the residue with a small quantity of pure, absolute ether, and with a small quantity of pure, absolute ether, and transfer to a small percolator or funnel, plugged with cotton. Wash with pure ether until at least 10 Cc. have passed through colorless, and reserve the ethereal washings. Redissolve the elaterin, so obtained, by passing chloroform through it while still in the funnel or percolator, and evaporate the chloroformic solution once more to dryness in a small dish. Treat the residue so obtained with ether, exactly as before. Allow the united ethereal washings to evaporate spontaneously until the bulk is reduced to about 3 Cc. Transfer this liquid to a small cylinder (e.g., a 10 Cc. measure), and allow the separated elaterin to deposit. Carefully decant the colored supernatant liquid, add 4 Cc. of pure ether to the residue, and again decant after deposition has taken place. Finally dissolve the elaterin in the cylinder with the aid of chloroform, and wash out the larger amount previously collected in the funnel with the same solvent. Unite the chloroformic solutions, evaporate in a tared dish, dry on a water-bath, and weigh."

the average yield of English elaterium was 21.5 per cent., of Maltese elaterium 15.3 per cent. (*P. J.*, Nov, 1891.)

Clutterbuck first observed that the activity of elaterium resided in the portion of it soluble in alcohol and not in water. This fact was afterwards confirmed by Paris, who found that the alcoholic extract, treated with boiling distilled water, and afterwards dried, had the property of purging in minute doses, while the remaining portion of the elaterium was inactive. The subsequent experiments of Hennell of London, and Morris of Edinburgh, which were nearly simultaneous, demonstrated the existence of a crystallizable matter in elaterium which is the active principle, and has been named *elaterin*. (See *Elatarium*.) According to Hennell, 100 parts of elaterium contain 44 of elaterin, 17 of a green resin (*chlorophyll*); 6 of starch, 27 of lignin, and 6 of saline matters. The alcoholic extract which Paris called *elatin* is probably a mixture of elaterin and the green resin or *chlorophyll*. Walz (1859) found in the juice of the fruits and herb of *Ecballium*, as well as in that of *Cucumis prophetarum*, L., a second crystallizable bitter principle, *prophetin*, and the amorphous substances *ecballin* or *elateric acid*, *hydro-elaterin*, and *elateride*, all of which require further examination.

Choice of Elaterium.—The inequality of elaterium depends probably more on diversities in the mode of preparation than on adulteration. Sometimes, however, it is greatly sophisticated, and large quantities are said to have been imported into this country consisting mainly of chalk colored green artificially. (*B. Canavan, N. Y. J. Pharm.*, iii.) It should possess the sensible properties above indicated as characterizing good elaterium, should not effervesce with acids, and should yield from one-sixth to one-fourth of elaterin. (See *Elatarium*.)

Uses.—Elatarium is a powerful hydragogue cathartic, and in a large dose generally excites nausea and vomiting. If too freely administered, it operates with great violence upon both the stomach and bowels, producing inflammation of these organs, which has in some instances eventuated fatally. It also increases the flow of urine. The fruit was employed by the ancients, and is recommended in the writings of Dioscorides as a remedy in mania and melancholy. Sydenham and his contemporaries considered elaterium highly useful in dropsy, but, in consequence of some fatal results from its incautious employment, it fell into disrepute, and was generally neglected till again brought into notice by Ferriar. It is now considered one of the most efficient hydragogue cathartics in the treatment of dropsy. The full dose of commercial elaterium as formerly found in commerce was often from one to two grains (0.065 to 0.13 Gm.), but, as the quality has greatly improved, this dose might now be much too large, and the best plan is to give it in the

dose of one-sixth to one-fourth of a grain (0.010 to 0.016 Gm.), repeated every hour till it operates, and increased if necessary. It should be observed that these doses are inapplicable to the very old and feeble and those prostrated by disease. Two-fifths of a grain (0.025 Gm.) proved fatal by purging in an ill and feeble lady of 70 years. (*A. J. P.*, 1868, p. 373.) The dose of Clutterbuck's elaterium is the eighth of a grain (0.008 Gm.), that of elaterin is from the twentieth to the fifteenth of a grain (0.003 to 0.004 Gm.). One grain may be dissolved in a fluidounce of alcohol with four drops of nitric acid, and from 25 to 30 minims (1.6 to 1.8 Cc.) may be given diluted with water, but the granule affords a preferable method.

Dose, one-tenth to one-half a grain (0.006 to 0.032 Gm.).

ELIXIR ADJUVANS. U. S.

ADJUVANT ELIXIR

(Ēl-ix'ir ād'ju-vāns)

Elixir adjuvant, *Fr.*; Gewürzhaftes Lakritzenelixir, *G.*

* "Fluidextract of Glycyrrhiza, one hundred and twenty cubic centimeters [or 4 fluidounces, 28 minims]; Aromatic Elixir, eight hundred and eighty cubic centimeters [or 29 fluidounces, 363 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix, and filter if necessary." *U. S.*

Uses.—This elixir is used as a vehicle for the administration of various medicinal preparations; it was introduced into the *U. S. Pharmacopœia* (8th Rev.) mainly to furnish an alternative elixir to aromatic elixir which is similarly used. The presence of the glycyrrhiza aids in disguising or obtunding the taste of bitter or disagreeable substances.

ELIXIR AROMATICUM. U. S.

AROMATIC ELIXIR [Simple Elixir]

(Ēl-ix'ir ār-q-māt'i-cūm)

Elixir aromatique, *Fr.*; Aromatisches Elixir, *G.*

* "Compound Spirit of Orange, twelve cubic centimeters [or 195 minims]; Syrup, three hundred and seventy-five cubic centimeters [or 12 fluidounces, 326 minims]; Purified Tale, thirty grammes [or 1 ounce av., 25 grains]; Alcohol, Distilled Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. To the Compound Spirit of Orange add enough Alcohol to make two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]. To this solution, add the Syrup in several portions, agitating after each addition, and afterwards add, in the same manner, three hundred and seventy-five cubic centimeters [or 12 fluidounces, 326 minims] of

Distilled Water. Mix the Purified Talc intimately with the liquid, and then filter through a wetted filter, returning the first portions of the filtrate until a transparent liquid is obtained. Lastly, wash the filter with a mixture of *one volume* of Alcohol and *three volumes* of Distilled Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” U. S.

This official preparation takes the place of the former elixir of orange, and by many is regarded as more agreeable. Its introduction grew out of the necessity for some official action which would enable pharmacists readily to furnish elixirs when called for by an extemporaneous or speedy process. The aromatic elixir is, of course, merely a base or vehicle, and in many cases the medicinal substance may be simply dissolved in the elixir. It may be necessary to add some insoluble, inert powder, like precipitated chalk, magnesium carbonate, etc., to the liquid before filtering, in order to obtain a perfectly transparent elixir, and it is customary in many parts of the country to color the preparation with cochineal or caramel.

Off. Prep.—Elixir Adjuvans, U. S.; Elixir Ferri, Quininæ et Strychninæ Phosphatum, U. S.; Liquor Ferri et Ammonii Acetatis, U. S.

ELIXIR FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U. S.

ELIXIR OF IRON, QUININE AND STRYCHNINE PHOSPHATES

(ēl-īx'īr fēr'ri quī-nī'næ ēt strých-nī'næ
phōs-phā'tum)

Elixir des Phosphates de Fer, de Quinine et de Strychnine, *Fr.*; Elixir von phosphorsauren Eisen, Chinin und Strychnin, *G.*

* “Soluble Ferric Phosphate, *seventeen and one-half grammes* [or 270 grains]; Quinine, *eight and seventy-five hundredths grammes* [or 135 grains]; Strychnine, *two hundred and seventy-five milligrammes* [or 4½ grains]; Phosphoric Acid, *two cubic centimeters* [or 32 minims]; Ammonium Carbonate, in translucent pieces, *nine grammes* [or 139 grains]; Alcohol, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Acetic Acid, *twenty-eight and sixty-five hundredths grammes* [or 1 ounce av., 5 grains]; Ammonia Water, Distilled Water, Aromatic Elixir, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Quinine and Strychnine in the Alcohol, then add the Phosphoric Acid and *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Aromatic Elixir. Add the Acetic Acid to the Ammonium Carbonate, contained in a suitable vessel, and when solution is complete, neutralize with Ammonia Water and add enough Distilled Water to make the product measure *fifty cubic centimeters* [or 1 fluidounce, 331 minims]. Mix the solution of Am-

monium Acetate with the solution of the alkalis, and add enough Aromatic Elixir to make the liquid measure *eight hundred and eighty cubic centimeters* [or 29 fluidounces, 363 minims]. Dissolve the Ferric Phosphate in *thirty cubic centimeters* [or 1 fluidounce, 7 minims] of Distilled Water, by the aid of a gentle heat, and if the solution be acid to litmus paper, neutralize exactly with Ammonia Water, and add enough Aromatic Elixir to make the product measure *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims]. Finally, mix the two solutions and filter if necessary.” U. S.

This elixir was introduced into the U. S. Pharmacopœia (8th Rev.) because it is largely used and deserved this recognition. The process is essentially that recommended by Caspari; the ferric phosphate and the alkalis can be retained in solution in the elixir with the aid of an excess of phosphoric acid, but this makes the elixir unpleasantly acid to the taste; ammonium acetate is used to retain the ferric phosphate in solution with the other ingredients and to make a finished elixir which can be mixed with aqueous solutions without producing turbidity, and remain clear at low temperatures. This elixir should be preserved in amber-colored bottles protected from the light, otherwise the pale greenish color which it has when first made will disappear and be replaced by a brownish tint followed often by precipitation.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

ELIXIRIA.

ELIXIRS

(ēl-īx-īr'ī-q)

Cordials; Elixirs, *Fr.*; Elixire, *G.*

Elixirs as they are known in modern American pharmacy are aromatic, sweetened, spirituous preparations, containing small quantities of active medicinal substances. They differ greatly from the liquids formerly termed elixirs, from the fact that the first object sought for in the modern elixir is an agreeable taste, and usually this is attained only by such sacrifices as to render the effect of the medicine almost *nil*, while the principal activity is due to the alcohol, which has proved in many cases very injurious. These considerations have prevented an extensive official recognition of elixirs, and the U. S. Pharm. 1890 recognized but two, one of which, the Aromatic Elixir, has been introduced merely as a vehicle. In the U. S. P. (8th Rev.) two elixirs were introduced, Adjuvant Elixir and Elixir of Iron, Quinine and Strychnine Phosphates.

Owing to their extensive use by practitioners all over our country, it became necessary to notice some of the most important in this commentary, and in the 15th edition of the Dispensatory a number of formulas for elixirs

were inserted in PART I. Elixir of Orange, official in the U. S. Pharm. 1880, may be made by the formula in the foot-note.¹

EMPLASTRA.

PLASTERS

(em-plās'trə)

Emplâtres, *Fr.*; Pflaster, *G.* Emplastri, *It.*; Emplastos, *Sp.*

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Spread plasters having rubber in their composition are most largely used; they are usually perforated. Some plasters have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the Pharmacopœias. Others owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and fats.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change color and to become hard and brittle, and, as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be excluded as much as possible. The defect may usually be remedied by melting the plaster with a moderate heat and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides

of wounds. The leather usually preferred is white sheepskin, or the kind known commercially as "hemlock splits." A margin about one-fourth or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper so cut as to leave in the centre a vacant space of the required dimensions, and removing the paper when no longer needed. The same object may often be accomplished by employing two narrow rulers of sheet tin graduated in inches, and so shaped that each of them may form two sides of a rectangle. These may be applied in such a manner as to enclose within them any given rectangular space, and may be fixed by weights upon the leather, or preferably adjusted by set screws, while the plaster is spread. For any other shape, as in the instance of plasters for the breast, pieces of tin may be employed having a space within, corresponding to the required outline. The spreading of the plaster is most conveniently accomplished by the use of a spatula or plaster iron. This may be heated by means of a spirit lamp. Care must be taken that the instrument be not so hot as to discolor or decompose the plaster, and special care is requisite in the case of those plasters which contain a volatile ingredient. A sufficient portion of the plaster should first be melted by the heated instrument, and, having been received on a piece of coarse stiff paper, or in a shallow tin tray open on one side, should, when nearly cool, be transferred to the leather, and applied quickly and evenly over its surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. Before removing the paper from the edge of the plaster, if this has become so hard as to crack, the iron should be drawn over the line of junction. When linen or muslin is used, and the dimensions of the portion to be spread are large, as is often the case with adhesive plaster, the best plan is to pass the cloth "on which the plaster has been laid through a machine formed of a spatula fixed by screws at a proper distance from a plate of polished steel." A machine for spreading plasters is described by M. Hérent in the *J. P. C.*, 3e sér., ii. 403. (See U. S. D., 18th edition, p. 498, also *N. R.*, 1879, p. 337.)

The spreading of plasters has become to a great extent a lost art to the pharmacists of this country, owing to the introduction of machine-spread plasters, which contain india-rubber in the adhesive composition. These are reasonably permanent, and do not require the application of heat. When made by reliable manufacturers they are in many cases to be preferred, but the introduction of immense quantities of worthless ones by unscrupulous makers has caused many practitioners to direct plasters to be spread by the pharmacist from official plaster. The perforation or "porous-

¹ *Elixir Aurantii*, U. S. 1880. *Elixir of Orange*. *Simple Elixir*.—"Oil of Orange Peel, one part [or two and a half fluidrachms]; Cotton, two parts [or half an ounce av.]; Sugar, in coarse powder, one hundred parts [or twenty-five ounces av.]; Alcohol, Water, each, a sufficient quantity, to make three hundred parts [or about four pints]. Mix Alcohol and Water in the proportion of one part [or one pint] of Alcohol to three parts [or two and a half pints] of Water. Add the Oil of Orange to the Cotton, in small portions at a time, distributing it thoroughly by picking the Cotton apart after each addition; then pack tightly in a conical percolator, and gradually pour on the mixture of Alcohol and Water, until two hundred parts [or three and one-fourth pints] of filtered liquid are obtained. In this liquid dissolve the Sugar by agitation, without heat, and strain." U. S. 1880.

ing" of plasters is usually accomplished on a large scale by expensive apparatus. J. J. Edmondson read a paper before the Pennsylvania Pharmaceutical Association in 1887 giving the process for manufacturing rubber-mass plasters as carried on by Johnson & Johnson of New York. It is as follows: The ingredients employed are—rubber, two parts; Burgundy pitch, one part, gum olibanum, one part. This may vary with some special plasters, but they constitute the component parts of the mass used for the majority.

The crude rubber is at first steeped in hot water, to cleanse and soften it, then the rubber is passed through the washer and crusher, where it is subjected to severe pressure between two corrugated rolls, eight inches in diameter and one foot wide, while a stream of water falling continually washes it thoroughly, and it comes out in sheets somewhat softened. After these sheets are dried, which requires a number of days, they are passed through the grinder, where they are crushed between two smooth rollers, fourteen inches in diameter and thirty-six inches across. This thoroughly softens the rubber and makes it plastic, so that it can be readily worked up with the other ingredients. The principal operation, the mixing, then takes place. The medication must be carefully combined, and the whole manipulation so managed that the plaster will be uniform, so that age or varying temperature shall not affect it. This operation is performed by means of rollers, sixteen inches in diameter, arranged so that one revolves at twice the speed of the other. Between these large rollers the mass is passed with whatever medication is required: *e. g.*, when a belladonna mass is to be made, a certain amount of the stock mass is taken and extract of belladonna in the proportions corresponding to the formula in the Pharmacopœia. These are repeatedly passed through the rollers until the extract of belladonna is thoroughly mixed with the mass, care being taken to keep the temperature from rising high enough to decompose or affect the alkaloids. The spreading is also done by rollers, into which the thoroughly mixed mass is fed at the same time that the cloth is fed, the thickness of the plasters being governed by the adjusting of screws on the side of the machine.

The rubber base is pliable, adhesive, it will not become too hard or too soft, but will yield up the medication to the absorbents of the skin, and its properties will be retained indefinitely.¹

¹ Certain plasters formerly recognized by the U. S. Pharmacopœia have been dropped in the various revisions, but as they are still liable to be called for we append the formulas for their preparation.

Emplastrum Aconiti. *Aconite Plaster.*—"Take of Aconite Root, in fine powder, sixteen troyounces; Alcohol, Resin Plaster, each, a sufficient quantity. Moisten the Aconite Root with six fluidounces of Alcohol, and pack it in a conical percolator. Cover the surface with a disk of paper, and pour upon it ten fluidounces of Alcohol. When the liquid begins to drop, cork the percolator, and, having closely covered it to prevent evaporation, set it aside in a

EMPLASTRUM ADHÆSIVUM.

U. S. (Br.)

ADHESIVE PLASTER

(em-pläs'trûm äd-hæ'sj-vûm)

Emplastrum Resinæ. *Br.*; Resin Plaster; *Emplâtre Adhésif.* *Emplâtre Résineux.* *Fr.*; Emplastrum adhæsivum, *P. G.*; Heftpflaster, *G.*; Emplastro adhesivo, *It.*

* "Rubber, cut in small pieces, twenty grammes [or 308.6 grains]; Petrolatum, twenty

moderately warm place for four days. Then remove the cork, and gradually pour on Alcohol until two pints of tincture have been obtained or the Aconite Root is exhausted. Distil off a pint and a half of alcohol, and evaporate the residue to a soft uniform extract by means of a water-bath. Add to this sufficient Resin Plaster, previously melted, to make the mixture weigh sixteen troyounces, and then mix them thoroughly." *U. S.* 1870.

Emplastrum Antimoni. *Antimonial Plaster.*—"Take of Tartrate of Antimony and Potassium, in fine powder, a troyounce; Burgundy Pitch four troyounces. Melt the Pitch by means of a water-bath, and strain; then add the powder, and stir them well together until the mixture thickens on cooling." *U. S.* 1870.

This is a useful formula, although no longer official. It affords one of the most convenient methods of obtaining the local pustulating effects of tartar emetic. For its effects and uses, see *Antimoni et Potassii Tartras*.

Emplastrum Arnice. *U. S.* 1890. *Arnica plaster.* "Extract of Arnica Root, three hundred and thirty grammes [or 11 ounces av., 280 gr.]; Resin Plaster, six hundred and seventy grammes [or 23 ounces av., 277 gr.], to make one thousand grammes [or 35 ounces av., 120 gr.]. Add the Extract to the Resin Plaster, previously melted by means of a water-bath, and mix them thoroughly." *U. S.* 1890.

Emplastrum Ferri. *U. S.* 1890. *Iron Plaster.* [Strengthening Plaster.] **Emplastrum Roborans.** *Br.* 1867.—"Ferrie Hydrate, dried at a temperature not exceeding 80° C. (176° F.), ninety grammes [or 3 ounces av., 76 grains]; Olive Oil, fifty grammes [or 1 ounce av., 334 grains]; Burgundy Pitch, one hundred and forty grammes [or 4 ounces av., 410 grains]; Lead Plaster, seven hundred and twenty grammes [or 25 ounces av., 173 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the Lead Plaster and Burgundy Pitch by means of a water-bath, and add the Olive Oil; then add the Ferrie Hydrate, and stir constantly until the mixture thickens on cooling." *U. S.* 1890.

Emplastrum Picis Burgundicæ. *U. S.* 1890. *Burgundy Pitch Plaster.*—"Burgundy Pitch, eight hundred grammes [or 28 ounces av., 96 grains]; Olive Oil, fifty grammes [or 1 ounce av., 334 grains]; Yellow Wax, one hundred and fifty grammes [or 5 ounces av., 127 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt together the Burgundy Pitch and Yellow Wax, then incorporate the Olive Oil, and stir constantly, until the mass thickens on cooling." *U. S.* 1890.

The object of the wax and olive oil is to give a proper consistence to the Burgundy pitch, and to prevent its great tendency to become brittle. Lavigne proposes to obviate the tendency of Burgundy pitch plaster to crack by incorporating with it caoutchouc, in the following method. Soften 35 parts, by weight, of caoutchouc, in small pieces, by warming it with 13 parts of petroleum in a close vessel. Melt together 300 parts of Burgundy pitch and 25 parts of white wax. Warm the solution of caoutchouc in a suitable vessel, add gradually, with constant stirring, the melted pitch and wax, and finally incorporate thoroughly with the mass 3 parts of glycerin. (*J. P. C.*, 4e sér., ix. 131.)

Emplastrum Resinæ. *U. S.* 1890. *Resin Plaster.* "Resin, in fine powder, one hundred and forty grammes [or 4 ounces av., 410 grains]; Lead Plaster, eight hundred grammes [or 28 ounces av., 96 grains]; Yellow Wax, sixty grammes [or 2 ounces av., 51 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the Lead Plaster and Yellow Wax together with a gentle heat; then add the Resin, and, when it is melted, mix the mass thoroughly." *U. S.* 1890.

grammes [or 308.6 grains]; Lead Plaster, *nine hundred and sixty grammes* [or 33 ounces av., 378 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Rubber at a temperature not exceeding 150° C. (302° F.); add the Petrolatum, and continue the heat until the Rubber is dissolved. Add the Lead Plaster to the hot mixture; continue the heat until it becomes liquid, then strain, allow it to cool, and stir until it stiffens." *U. S.*

"Resin, 4 ounces (Imperial) or 100 grammes; Lead Plaster, 2 pounds (Imp.) or 800 grammes; Hard Soap, 2 ounces (Imp.) or 50 grammes. Melt each ingredient separately at as low a temperature as possible; mix." *Br.*

The name of this plaster was changed in the U. S. P. (8th Rev.) to adhesive plaster, it was formerly termed resin plaster and is still so named in the British Pharmacopœia. It differs from lead plaster in being more adhesive and somewhat more stimulating. It resembles the common adhesive plaster of commerce, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other and a firm support is given to the granulations. The U. S. (8th Rev.) formula differs from that official in 1890 in the use of rubber and petrolatum in place of yellow wax and rosin; the object of these additions to the lead plaster base is to give pliability and greater adhesiveness. It is used in several official plasters. As prepared by the Dublin College it contained soap, which gave it greater pliability, and rendered it less liable to crack in cold weather, without impairing its adhesiveness, and the process of that College has been adopted in the British Pharmacopœia. It is usually spread upon muslin, and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept ready spread by the pharmacist; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. Adhesive plaster originally employed by Baynton contained only six drachms of rosin to the pound of lead plaster. To obviate the possibility of irritating the skin, Herpin recommends the addition of lead tannate, the proportion of which, when adhesiveness is required in the plaster, should not exceed one-twentieth, but under other circumstances may be increased to one-twelfth. (*Bull. de Thérap.*, xlviii. 155.)

The addition of Burgundy pitch or turpentine is objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. *Br.*

AMMONIACUM AND MERCURY PLASTER

(em-plās'trūm ām-mō-nī'ā-eī cūm hŷ-drār'gy-rō)

Ammoniac Plaster with Mercury; Emplâtre de Gomme Ammoniaque mercuriel, *Fr.*; Quecksilber- und Ammoniak-pflaster, Quecksilberhaltiges Ammoniakpflaster, *G.*

The U. S. P. 1890 process is appended.

"Ammoniac, *seven hundred and twenty grammes* [or 25 ounces av., 173 grains]; Mercury, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Oleate of Mercury, *eight grammes* [or 123 grains]; Diluted Acetic Acid, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]; Lead Plaster, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Digest the Ammoniac with the Diluted Acetic Acid, in a suitable vessel, avoiding contact with metals, until it is entirely emulsified; then strain, and evaporate the strained liquid by means of a water-bath, stirring constantly, until a small portion, taken from the vessel, hardens on cooling. Triturate the Oleate of Mercury with the Mercury gradually added, until globules of the metal cease to be visible. Next add, gradually, the Ammoniac, while yet hot; and finally, having added enough Lead Plaster, previously melted by means of a water-bath, to make the mixture weigh *one thousand grammes* [or 35 ounces av., 120 grains], mix the whole thoroughly." *U. S.* 1890.

"Ammoniacum, 12 ounces (Imperial) or 328 grammes; Mercury, 3 ounces (Imp.) or 82 grammes; Olive Oil, 56 grains (Imp.) or 3.5 grammes; Sublimed Sulphur, 8 grains (Imp.) or 0.5 gramme. Heat the Olive Oil; add the Sulphur to it gradually, stirring until they are uniformly blended; with this mixture triturate the Mercury until metallic globules are no longer visible; add the Ammoniacum, previously purified by boiling with successive portions of water, passing the resulting emulsions through, while rubbing the residues on, a hair sieve, and, after mixing, evaporating the emulsions to a suitable consistence." *Br.*

Ammoniac plaster (Emplastrum Ammoniaci, U. S. P. 1880) was not recognized in the last U. S. and *Br. Pharmacopœias*. (See U. S. D., 17th ed., 492.) Ammoniac plaster with mercury U. S. 1890 did not differ materially from that produced by the formula of the U. S. P. 1880. The use of diluted acetic acid to facilitate the straining of the ammoniac is an improvement over the water formerly used. The use of lead plaster to bring up the weight is needless, in our opinion. The use of the oleate of mercury is to aid in the extinguishment of the mercury and the compound formed by it probably adds to the efficiency. When ammoniac not previously prepared is used, as it is not fusible by heat, it must be brought to the proper consistence by softening it in a small quantity of hot water, straining and evaporating. This

plaster unites with the stimulant power of the ammoniac the specific properties of the mercury, which is sometimes absorbed in sufficient quantity to affect the gums. It is used as a discutient in *enlargement of the glands*, tumefaction of the joints, nodes, and other indolent swellings, especially when dependent on a venereal taint. It is also sometimes applied over the liver in *chronic hepatitis*.

EMPLASTRUM BELLADONNÆ.

U. S., Br.

BELLADONNA PLASTER

(em-plās'trūm bēl-lā-dōn'æ)

"Belladonna Plaster should contain not less than 0.38 percent. nor more than 0.42 percent. of mydriatic alkaloids." U. S.

Emplâtre de Belladone, Fr.; Belladonna-Pflaster, G.; Emplasto de belladonna, Sp.

* "Extract of Belladonna Leaves, *three hundred grammes* [or 10 ounces av., 255 grains]; Adhesive Plaster, *seven hundred grammes* [or 24 ounces av., 303 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Adhesive Plaster on a water-bath, add to it the Extract of Belladonna Leaves, softened by the heat of a water-bath, and continue the heat, stirring constantly until the mixture is perfectly homogeneous; then allow it to cool. Spread Belladonna Plasters made with a rubber base should yield, when assayed by the process given below, not less than 0.38 percent. nor more than 0.42 percent. of mydriatic alkaloids." U. S.

"Liquid Extract of Belladonna, 4 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Resin Plaster, 5 *ounces* (Imp.) or 125 grammes. Evaporate the Liquid Extract of Belladonna on a water-bath until it is reduced in weight to *one ounce* (Imp.) or twenty-five grammes; add the Resin Plaster previously melted; mix. This Plaster contains 0.5 per cent. of the alkaloids of Belladonna Root." Br.

The U. S. Pharmacopœia (8th Rev.) provides a standard not only for the plaster made by the process above given, but for rubber base belladonna plasters, which are so largely employed throughout the country. For the official process the extract of belladonna leaves used is the standardized official extract containing 1.4 per cent. of mydriatic alkaloids; for the rubber base plasters made by the manufacturers not less than 0.38 per cent. nor more than 0.42 per cent. of mydriatic alkaloids is the standard.

Assay of Belladonna Plaster (Rubber Base).

U. S. (8th Rev.)—"Belladonna Plaster, spread upon cloth, *ten grammes*; Chloroform, Ammonia Water, Alcohol, Distilled Water, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., each, a *sufficient quantity*. Into a suitable beaker containing 50 Cc. of chloroform and 3 Cc. of ammonia water, in-

troduce the Belladonna Plaster cut into strips. Stir until the Plaster is entirely removed from the cloth; then pour off the chloroform into another beaker, wash the cloth with 25 Cc. of chloroform and 1 Cc. of ammonia water carefully, and add the washings to the chloroformic solution first obtained. If necessary, repeat the washing with 25 Cc. of chloroform, and add this also to the chloroformic solution. Then dry the cloth at a low temperature; cool and weigh it, and subtract its weight from the original weight of the Plaster. To the chloroformic solution, add four-fifths of its volume of alcohol, stir gently, and allow the liquid to stand until all of the rubber has separated in a compact mass. Then pour off the supernatant liquid into a separator of 250 Cc. capacity, and, having prepared a solution of sulphuric acid by diluting 40 Cc. of normal sulphuric acid V.S. with 60 Cc. of distilled water, add 20 Cc. of the solution to the separator, and agitate for two minutes, rotating gently. Draw off the chloroformic solution into another separator, shake this with 10 Cc. of the sulphuric acid solution, and add the acid solution to that in the first separator. Repeat until the acid washings cease to give a reaction with mercuric potassium iodide T.S.; combine the acid liquids, and, having rendered this solution alkaline with ammonia water, shake out the alkaloids with three successive portions of 25, 15, and 10 Cc. of chloroform. Collect these in a flask, distil off all of the chloroform with the aid of a water-bath. To the alkaloidal residue add a slight excess of tenth-normal sulphuric acid V.S., noting the quantity used, and then add 10 drops of chloroform and, after rotating, evaporate the latter by means of a water-bath. Then add 5 drops of hematoxylin T.S., and, rotating, titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from the number of cubic centimeters of tenth-normal sulphuric acid V.S. first added, and divide the difference by the number of grammes of Belladonna Plaster separated from the cloth; multiply the quotient by 0.0287, and this product by 100, which will give the percentage of mydriatic alkaloids in the Belladonna Plaster." U. S.

This plaster was formerly prepared, in both Pharmacopœias, with the extract made from the inspissated juice of the leaves, but in the U. S. P. 1880 an alcoholic extract of the root was substituted, with the effect of rendering the plaster easier to be spread and more adhesive, and giving it a light yellowish-brown color, without a shade of green. The official preparation is now of a brownish-green color, due to the extract of belladonna leaves. It is a useful anodyne application in *neuralgic* and *rheumatic pains*. We have seen the constitutional effects of belladonna result from its external use. T. W. Worthington proposed a formula for making belladonna plaster with caoutchouc in the A. J. P., xliii. 153. (See page 436.) Machine-

spread belladonna plaster can be found in the market which was admitted by a representative of the manufacturer to contain no extract of belladonna whatever. For methods of assaying belladonna plasters see *A. J. P.*, 1898, 182, 293. Extract of scopolia is largely used by manufacturers in making rubber base belladonna plaster.

EMPLASTRUM CALEFACIENS. Br.

WARMING PLASTER

(em-plās'trūm cāl-e-fā'c-jēns)

Warm Plaster; Emplâtre de Poix cantharidé, *Fr.*; Pechplaster mit Canthariden, *G.*

Cantharidal pitch plaster or warming plaster is not official in the U. S. P. (8th Rev.); the process of the U. S. P. 1890 is appended.¹

"Cantharides, in coarse powder, 4 ounces (Imperial) or 100 grammes; Yellow Beeswax, 4 ounces (Imp.) or 100 grammes; Resin, 4 ounces (Imp.) or 100 grammes; Resin Plaster, 3½ pounds (Imp.) or 1300 grammes; Soap Plaster, 2 pounds (Imp.) or 800 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 500 cubic centimetres. Infuse the Cantharides in the Distilled Water for six hours; squeeze strongly through calico; evaporate the expressed liquid on a water-bath till reduced to one-third; add the other ingredients; melt on a water-bath; stir until the ingredients are thoroughly mixed." *Br.*

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication. As prepared by the U. S. 1870 process it occasionally blistered, and the proportion of cantharides was, therefore, considerably diminished in the U. S. 1880 and 1890 formulas. This was unfortunate; for, while such a reduction may render the plaster insufficiently active in most cases, it does not entirely obviate the objection, as the smallest proportion of flies, or even the Burgundy pitch alone, would vesicate in certain persons. In whatever mode, therefore, this plaster may be prepared, it cannot always answer the expectations which may be entertained, and the only plan, when the skin of any individual has been found to be very susceptible, is to accommodate the proportions to the particular circumstances of the case. Much, however, may be accomplished by care in the preparation of

the plaster, towards obviating its tendency to blister. If the flies of the *cerate of cantharides* have been coarsely pulverized, the latter particles, coming in contact with the skin, will exert upon the particular part to which they may be applied their full vesicatory effect, while if reduced to a very fine powder they would be more thoroughly enveloped in the other ingredients, and thus have their strength much diluted. Hence the cerate, when used as an ingredient of the warming plaster, should contain the cantharides as minutely divided as possible, and the direction given in the U. S. 1890 process to strain it through cloth of fine texture should be carefully observed. The plan of keeping the cerate used in this preparation for a considerable time at the temperature of 100° C. (212° F.), and then straining it so as to separate the flies, is a good one, but it would be better yet to substitute cerate of the extract of cantharides for the cerate of cantharides. (See *Ceratum Cantharidis*.) The mode frequently pursued of preparing the warming plaster by simply sprinkling a very small proportion of powdered flies upon the surface of Burgundy pitch is altogether objectionable. It has been objected to the former U. S. plaster that it is liable to be too soft in hot weather. G. C. Close, ascribing this inconvenience to the proportion of lard in the cerate employed, proposed to obviate it by substituting Burgundy pitch plaster for Burgundy pitch, and powdered cantharides for the cerate, and offered a formula in accordance with this suggestion. (See *A. J. P.*, 1867, p. 20; from *Proc. A. Ph. A.*, 1866.)

Warming plaster is employed in *chronic rheumatism*, and in chronic internal diseases attended with inflammation, such as *catarrh, asthma, pertussis, phthisis, hepatitis*, and the sequelæ of *pleurisy and pneumonia*.

EMPLASTRUM CANTHARIDIS. Br.

CANTHARIDES PLASTER

(em-plās'trūm cān-thār'ī-dīs)

See *Ceratum Cantharidis*. U. S.

EMPLASTRUM CAPSICI. U. S.

CAPSICUM PLASTER

(em-plās'trūm cāp'sī-ci)

Sparadrapum Capsici; Sparadrap de Capsique, *Fr.*; Capsicumplaster, *G.*

* "Oleoresin of Capsicum, twenty-five hundredths of a gramme [or 4 grains]; Adhesive Plaster, spread on fabric, a sufficient quantity. Apply the Oleoresin of Capsicum to the surface of the Adhesive Plaster by means of a brush, so as to form a thin coating over an area fifteen centimeters [five and fifteen-sixteenths inches] square, leaving a margin around the sides." *U. S.*

¹ *Emplastrum Picis Cantharidatum*, U. S. 1890. "Cerate of Cantharides, eighty grammes [or 2 ounces av., 359 grains]; Burgundy Pitch, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the Cerate of Cantharides on a water-bath containing boiling water, and continue the heat for fifteen minutes; then strain it through a piece of muslin of close texture so that the Cantharides will be retained on the muslin. To the strained liquid add a sufficient quantity of Burgundy Pitch to make the whole weigh one thousand grammes [or 35 ounces av., 120 grains], render the mixture homogeneous by stirring, remove the heat, and stir the mass until it thickens on cooling." *U. S.* 1890.

This affords a convenient way of obtaining the rubefacient effects of capsicum; of course the practice will be for the pharmacist to employ machine-spread adhesive plaster as the base; although, with a little experience, very good work can be done by hand.

EMPLASTRUM HYDRARGYRI.

U. S., Br.

MERCURIAL PLASTER.

(em-plās'trūm hŷ-drār'gy-ri)

Emplastrum Mercuriale; Emplâtre mercuriel, *Fr. Cod.*; Emplastrum Hydrargyri, *P. G.*; Quecksilberplaster, *G.*; Emplastro mercuriale, *It.*

* "Mercury, *thirty grammes* [or 1 ounce av., 25 grains]; Oleate of Mercury, *one gramme* [or 15 grains]; Hydrous Wool-Fat, *ten grammes* [or 154 grains]; Lead Plaster, *fifty-nine grammes* [or 2 ounces av., 36 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Mercury with the Oleate of Mercury until the former is thoroughly divided, then add the Hydrous Wool-Fat, and continue the trituration until globules of Mercury are no longer visible. Add the mixture to the Lead Plaster, which has previously been melted in a tared dish, and incorporate thoroughly, adding, if necessary, sufficient Lead Plaster to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]." *U. S.*

"Mercury, 3 ounces (Imperial) or 82 grammes; Olive Oil, 56 grains (Imp.) or 3.5 grammes; Sublimed Sulphur, 8 grains (Imp.) or 0.5 gramme; Lead Plaster, 6 ounces (Imp.) or 164 grammes. Heat the Olive Oil; add the Sulphur to it gradually; stir until they are uniformly blended; with this mixture triturate the Mercury until metallic globules are no longer visible; add the Lead Plaster previously melted; mix." *Br.*

The present official process differs from that of the U. S. Pharm. 1880 in employing oleate of mercury and hydrous wool-fat for the purpose of extinguishing the mercury; this it does effectually, and at the same time increases the efficiency of the mercurial constituent. The quantity of mercury is 30 per cent. The British preparation is stronger, containing nearly 50 per cent.

The U. S. and former British processes may be considered identical in their results. The sulphuretted oil which was employed in the process of the London College to facilitate the extinguishment of the mercury was abandoned in the first British Pharmacopœia, as just in proportion to the increased facility of the process it lessened the efficacy of the resulting plaster, mercury sulphide being wholly inert. Nevertheless, the Br. Pharmacopœia has in its last revision revived the old London formula. Thomas Blunt has found it almost impossible to divide the mercury sufficiently by trituration with oil and rosin, and the resulting plaster was

so crumbly that it could not be formed into rolls; but on substituting a weight of Venice turpentine equal to that of the oil and rosin combined, he found it to answer completely. An objection, however, to the turpentine is, that it might render the plaster too irritant for susceptible skins. (*P. J.*, 1864, p. 56.)

This plaster is employed to produce the local effects of mercury upon syphilitic lesions of the skin and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. It occasionally affects the gums.

From observations made in France by Serres and others, it appears that the mercurial plaster of the Codex¹ (*Emplastrum (Emplâtre) de Vigo cum Mercurio*) has the power, when applied over the eruption of *small pox*, before the end of the third day from its first appearance, to check its progress and prevent supuration and pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. That the local effect is not ascribable to the mere exclusion of the air is proved by the fact that the use of lead plaster was not followed by the same results. It is probable that other mercurial preparations would answer the same purpose.

EMPLASTRUM MENTHOL. Br.

MENTHOL PLASTER

(em-plās'trūm mēn'thōl)

Emplâtre de Menthol, *Fr.*; Mentholplaster, *G.*

"Menthol, 1½ ounces (Imperial) or 30 grammes; Yellow Beeswax, 1 ounce (Imp.) or 20 grammes; Resin, 7½ ounces (Imp.) or 150 grammes. Melt the Beeswax and Resin together; when the mixture approaches the temperature of 160° or 170° F. (71.1° or 76.7° C.), stir in the Menthol until dissolved." *Br.*

This is an official plaster of the British Pharmacopœia, having been introduced in the additions in 1885; the present plaster is, however, 5 per cent. weaker in menthol than that formerly official. It is a mild counter-irritant, intended especially for relief in localized *neuralgia* and *rheumatic pains*.

¹ *Emplastrum (Emplâtre) de Vigo cum Mercurio.* "Take of simple plaster [lead plaster] *forty ounces*; yellow wax *two ounces*; resin *two ounces*; ammoniac, bdellium, olibanum, and myrrh, each, *five drachms*; saffron *three drachms*; mercury *twelve ounces*; turpentine [common European] *two ounces*; liquid storax *six ounces*; oil of lavender *two drachms*. Powder the gum-resins and saffron, and rub the mercury with the storax, turpentine and oil of lavender in an iron mortar until completely extinguished. Melt the plaster with the wax and resin, and add to the mixture the powders. When the plaster shall have been cooled, but while it is yet liquid, add the mercurial mixture, and incorporate the whole thoroughly." This should be spread upon leather or linen cloths, and applied so as effectually to cover the part to be protected.

EMPLASTRUM OPII. U. S., Br.

OPIUM PLASTER

(em-plās'trūm ō'pī-i)

Emplastrum Opiatum, Emplastrum Cephalicum, s. Odontalgicum; Emplâtre d'Opium, Emplâtre céphalique (temporal, odontalgique, calmant), Fr.; Opiumpflaster, Hauptpflaster, G.

* "Extract of Opium, *six grammes* [or 92.5 grains]; Water, *eight cubic centimeters* [or 130 minims]; Adhesive Plaster, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Extract of Opium with the Water until it is uniformly soft; add it to the Adhesive Plaster, which has been previously melted in a tared dish on a water-bath, and continue the heat with constant stirring until the product weighs *one hundred grammes* [or 3 ounces av., 231 grains]." U. S.

"Opium, in very fine powder, 1 ounce (Imperial) or 10 grammes; Resin Plaster, 9 ounces (Imp.) or 90 grammes. Melt the Resin Plaster on a water-bath; stir in the Opium gradually." Br.

We decidedly prefer the extract of opium, as employed in the present U. S. process, to the powdered opium of the British formula. It not only forms a better plaster, but, being soluble, is more likely to produce the anodyne effect desired, by being brought by the perspiration to the liquid state necessary for its absorption. The use of water in the present process is also an advantage, as it enables the opium to be more thoroughly incorporated with the other ingredients; but care should be taken that the moisture is well evaporated. The opium plaster is intended to be used for the relief of *rheumatic* and other *pains* in the parts to which it is applied.

EMPLASTRUM PICIS. Br.

PITCH PLASTER

(em-plās'trūm pī'cīs)

Burgundy Pitch Plaster; Emplastrum Picis Burgundicæ; Emplâtre de Poix de Bourgogne, Fr.; Burgunder-Pechpflaster, G.

"Burgundy Pitch, 26 ounces (Imperial) or 520 grammes; Frankincense [Terebinthina, U. S.], 13 ounces (Imp.) or 260 grammes; Resin, 4½ ounces (Imp.) or 90 grammes; Yellow Beeswax, 4½ ounces (Imp.) or 90 grammes; Olive Oil, 2 ounces (Imp.) or 40 grammes; Distilled Water, 2 fl. ounces (Imp. meas.) or 40 cubic centimetres. Add the Olive Oil and the Water to the Frankincense, Burgundy Pitch, Resin, and Beeswax, previously melted together; evaporate with constant stirring to a proper consistence." Br.

This is a rubefacient plaster, which closely resembles the Burgundy pitch plaster of the U. S. P. 1890. (See page 436.) The expressed

oil of nutmeg directed in the Br. Pharm. of 1885 was not retained in the present British authority; it was an unnecessary addition. This plaster is applicable to catarrhal and other pectoral affections, *chronic inflammation of the liver*, and *rheumatic pains* in the joints and muscles. It often keeps up a serous discharge, which requires that it should be frequently renewed. The irritation which it excites is sometimes so great as to render its removal necessary.

EMPLASTRUM PLUMBI. U. S., Br.

LEAD PLASTER [Diachylon Plaster]

(em-plās'trūm plūm'bī)

Emplastrum Lithargyri, Br. 1864; Emplastrum Diachylon Simplex, Emplastrum Album Coctum; Litharge Plaster; Emplâtre simple, Fr. Cod.; Emplâtre de Plomb (de Litharge), Emplastrum simplex, Fr.; Emplastrum Lithargyri (simplex), P. G.; Emplastrum Cerusæ, Froschlachpflaster; Bleipflaster, Diachylonpflaster, G.; Emplastro diachylon, It.; Emplastro de plomo simple, Emplastro simple, Sp.

* "Soap, dried, and in coarse powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Lead Acetate, *sixty grammes* [or 2 ounces av., 51 grains]; Water, *a sufficient quantity*. Dissolve the Soap in *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of hot Water and strain the solution. Dissolve the Lead Acetate in *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of hot Water, and at once filter the solution into the warm Soap solution, stirring constantly. When the precipitate has subsided, decant the liquid, and wash the precipitate thoroughly with hot Water. Transfer the mass to a warm slab, kneading it thoroughly to free it from water. Finally, roll the plaster into cylindrical forms and wrap them in paraffined paper." U. S.

"Lead Oxide, 1 pound (Imperial) or 400 grammes; Olive Oil, 2 pounds (Imp.) or 800 grammes; Distilled Water, 16 fl. ounces (Imp. meas.) or 400 cubic centimetres or a sufficient quantity. Boil all the ingredients together gently by the aid of a steam-bath; keep them simmering for four or five hours, stirring constantly until the product acquires a proper consistence for a plaster; add more of the Distilled Water during the process if necessary." Br.

The importance of this plaster, as the basis of most of the others, requires a somewhat detailed account of the principles and manner of its preparation. A very important change was made in the process for lead plaster in the U. S. Pharmacopœia (8th Rev.). The old method of boiling litharge, olive oil, and water together, which is still official in the British Pharmacopœia, was discarded and the precipitation method introduced. The resulting product is chemically nearly identical with that made by the boiling process and is much whiter

in color, while the adhesiveness of the present plaster seems to be superior to that of the U. S. P. 1890.¹

The reaction in the U. S. P. (8th Rev.) process, disregarding the palmitin present, is as follows:

In the British process and that of the U. S. P. 1890 a reaction takes place between the oil and water, resulting in the development of *glycerin*, and of two acid bodies, *oleic* and *palmitic acids*, to which, when animal fat is employed instead of olive oil, a third is added,—namely, *stearic acid*. The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact a lead oleo-palmitate, and if the olive oil contained stearin it would be a lead oleo-stearo-palmitate. The *glycerin* remains dissolved in the water, or mechanically mixed with the plaster. That such is the correct view of the nature of this compound is evinced by the fact that, if the lead oxide be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water. The fixed or fatty oils are compounds of the free fatty acids mentioned and the radical *glyceryl*. When boiled with the lead oxide and water, the fatty acids combine with the metallic oxide to form the plaster, and the *glyceryl* unites with the hydroxyl and becomes *glycerin*. The British process does not provide for the separation of the *glycerin* and the plaster is not kneaded to separate the water, both of which, in our opinion, are necessary to produce the best result and which form part of the U. S. P. 1890 process.

The reaction between olein and lead oxide is as follows:

The radical *glyceryl* (C_3H_5) is a triad, and combines with three groups of a fatty acid or three groups of hydroxyl (OH).

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to Henry of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of lead plaster to the German. From experiments of Soubeiran, it appears that massicot or even minium may be substituted for litharge, and a plaster of good consistence be obtained, but that a much longer time is required for completing the process than when the official formula is followed. Owing to the necessity for its partial deoxidation, the use of minium requires a longer continuance of the process than when massicot is employed. According to Davallon, it is important that the olive oil employed should be pure, for when adulterated, as it frequently is, it yields an imperfect product.

N. S. Thomas prepared a good plaster by substituting lard for olive oil, in the proportion of eight pounds of lard to five of litharge (*A. J. P.*, xix. 175), and we are told that it is a common practice in this country to make lead plaster with a mixture of lard oil and olive oil. Mueller uses equal parts of lard, olive oil, and litharge, having previously heated the litharge until a small sample causes no effervescence when dropped into nitric acid, showing the absence of carbonate. (*Ph. Zig.*, 1879, p. 70; *A. J. P.*, 1879, p. 190.) It is said that the English plaster makers rarely follow the Br. Pharm. direction, preferring the recipe of the old London Pharmacopœia, which contains more litharge and yields a much firmer and less adhesive product.¹ (*P. J.*, 3d ser., p. 701, 716.)

The process of the United States Pharmacopœia by precipitation is well adapted for making comparatively small quantities of lead plaster, but some manufacturers prefer the boiling process when large quantities are to be made, and the following details are retained: The vessel in which the lead plaster is prepared

¹ *Emplastrum Plumbi*. U. S. 1890.—“Lead Oxide, three thousand two hundred grammes [or 112 ounces av., 383 grains]; Olive Oil, six thousand grammes [or 211 ounces av., 282 grains]; Water, a sufficient quantity. Mix the Lead Oxide, previously passed through a No. 80 sieve, intimately with about one-half of the Olive Oil, by trituration, and add the mixture to the remainder of the Oil contained in a bright copper boiler of a capacity equal to at least four times the bulk of the ingredients. Then add one thousand cubic centimeters [or 33 fluidounces, 63 fluidrachms] of boiling Water, and boil the whole together, over a fire, constantly stirring with a wooden spatula, until a small portion, when dropped into cold water, is found to be pliable and tenacious. From time to time add a little Water to replace that lost by evaporation. When the contents of the boiler have acquired a whitish color and are perfectly homogeneous, transfer them to a vessel containing warm Water, and as soon as the mass has sufficiently cooled, knead it well with the Water so as to remove the *glycerin*, renewing the Water from time to time, as long as it may be necessary. Finally divide the mass into rolls of suitable size.” U. S. 1890.

¹ *Schwarze's Mutterpflaster, Emplastrum Fuscum* of the German Pharmacopœia, is made by boiling 64 parts of olive oil with 32 parts of very finely powdered red lead in a copper kettle until the mass is dark brown, and then adding 16 parts of yellow wax. *Emplastrum Fuscum Camphoratum* is the same with the addition of 1 per cent. of camphor. *Zinc Plaster*.—De Mussey, having witnessed inconveniences from lead plaster in consequence of the absorption of the lead, substituted for it a plaster with a basis of zinc oxide, which he has found to answer very well in practice. It cannot be made by direct combination of the oxide, and it is necessary to have recourse to the method of double decomposition. Solutions of white olive oil soap and of zinc sulphate being mixed, a copious precipitate takes place of zinc oleo-palmitate, which, after being washed and dried, may be combined with resins, oil, and wax, to give it the necessary consistence. (*J. P. C.*, xxvii. 100.)

should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would therefore delay the process. While the water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil, and cause the reduction of the oxide. The waste must, therefore, be supplied by fresh additions as directed in the process, and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator.

During the continuance of the boiling, the material should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably, in consequence partly of the vaporization of the water, partly of the escape of carbon dioxide, which is liberated by the oily acids from some lead carbonate usually contained in the litharge. The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the color and consistence of the mass. The color of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick when a portion of the plaster, taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red points, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and, having been well kneaded under water, in order to separate the viscid solution of glycerin contained in the interior, should be formed into cylindrical rolls, and wrapped in paper. Such, at least, has been the course of proceeding usually recommended. But Davallon maintains that the presence of glycerin in the plaster is useful by keeping it in a plastic state, and that washing and kneading are injurious, the former by removing the glycerin, the latter by introducing particles of air and moisture into the mass, which is thus rendered more disposed to rancidity. (*A. J. P.*, xv. 274; from *Journ. de Chim. Méd.*) By employing steam heat in the preparation of this plaster, the risk of burning it is avoided. Bernbeck found that

lead plaster could be preserved from hardening and oxidation if kept in air tight canisters. (*Ph. Ztg.*, 1881, p. 589.)

C. Lewis Diehl found it almost impossible, in following the U. S. directions of 1860, to obtain a plaster wholly free from uncombined litharge. He obviated the difficulty by first rubbing the sifted litharge with about half its weight of oil, then stirring the mixture with the remainder of the oil, in a tinned copper kettle, adding the water, and heating to 212° F. until a uniform plaster was formed. (*A. J. P.*, 1867, p. 385.)

Uses.—This plaster, which has long been known under the name of *diachylon*, is used as an application to excoriated surfaces and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead colic resulted from its long continued application to a large ulcer of the leg. (*Am. J. M. S.*, xxiii. 246.) J. M. Bigelow reports a case of excessive sweating of the feet cured by putting the patient in bed for thirteen days and keeping the feet enveloped in strips of lead plaster. (*N. R.*, Oct. 1875.) Its chief use is in the preparation of other plasters.¹

Off. Prep.—Emplastrum Adhæsivum, U. S. (*Br.*); Emplastrum Hydrargyri, U. S., *Br.*; Emplastrum Plumbi Iodidi, *Br.*; Emplastrum Saponis, U. S., *Br.*; Unguentum Diachylon, U. S.

EMPLASTRUM PLUMBI IODIDI. *Br.*

LEAD IODIDE PLASTER

(em-pläs'trüm plūm'bī i-ōd'i-di)

Emplâtre d'Iodure de Plomb, *Fr.*; Jodbleipflaster, *G.*

"Lead Iodide, 2 ounces (Imperial) or 50 grammes; Lead Plaster, 1 pound (Imp.) or 400

¹ *Logan's Plaster.*—Take of Litharge, Lead Carbonate, each, 1 pound; Castile Soap, twelve ounces; Butter (fresh), four ounces; Olive Oil, two and a half pints; Mastic, in powder, two drachms. It is to be understood that the pound and ounce are of the avoirdupois weight. Having mixed the Soap, Oil, and Butter, add the Litharge, and boil the mixture gently, constantly stirring, for an hour and a half, or until it shall assume a pale brown color; then increase the heat somewhat, and continue to boil, until a portion of the liquid, dropped on a smooth board, is found not to adhere to it on cooling; then remove it from the fire, and mix the mastic with it. Logan's plaster is yet employed by regular practitioners as a protective and discutient application.

Plaster of Lead Carbonate.—This was originally introduced into our Pharmacopœia as a substitute for *Mahy's plaster*, at one time much employed in some parts of the United States, but was omitted in the edition of 1840. It is a good application to surfaces inflamed or excoriated by friction, and may be resorted to with advantage in those troublesome cases of cutaneous irritation, and even ulceration, which are likely to occur upon the back and hips during long continued confinement to one position. We give the process as contained in the Pharmacopœia of 1830. "Take of Carbonate of Lead a pound; Olive Oil two pints; Yellow Wax four ounces; Lead Plaster a pound and a half; Florentine Orris, in powder, nine ounces. Boil together the Oil and Carbonate of Lead, adding a little water and constantly stirring, till they are thoroughly incorporated; then add the

grammes; Resin, 2 ounces (Imp.) or 50 grammes. Finely powder the Lead Iodide; mix it with the Lead Plaster and Resin previously melted together at as low a temperature as possible." *Br.*

This is a local discutient plaster, which may also be used with other means to affect the system. (See *Plumbi Iodidum*.)

EMPLASTRUM SAPONIS. U. S., *Br.*

SOAP PLASTER

(em-pläs'trūm sã-pō'nīs)

Emplâtre de Savon, Fr. Cod.; Emplastrum cum Sapone, Fr.; Emplastrum Saponatum, P. G.; Seifenplaster, G.; Emplasto de jabon, Sp.

* "Soap, dried, and in coarse powder, *ten grammes* [or 154 grains]; Lead Plaster, *ninety grammes* [or 3 ounces av., 76 grains]; Water, a sufficient quantity, to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Soap with enough Water to reduce it to a semi-liquid state; then mix it with the Lead Plaster previously melted, incorporate thoroughly by stirring, and evaporate to the proper consistence." *U. S.*

"Hard Soap, 6 ounces (Imperial) or 150 grammes; Lead Plaster, 2½ pounds (Imp.) or 900 grammes; Resin, 1 ounce (Imp.) or 25 grammes. Melt each ingredient separately at a low temperature; mix; evaporate, with constant stirring, to a proper consistence." *Br.*

The present *U. S.* formula is an improvement upon that of a former edition of the Pharmacopœia. By directing the soap to be in powder instead of sliced, it may be more thoroughly incorporated with the plaster. Greater plasticity is secured, in some degree, in the British process by the use of resin. Diehl adopted the plan of first rubbing the soap with its weight of water, then straining the mixture through coarse muslin, and lastly reducing the residue with a proportionate quantity of water, before stirring the whole into the melted plaster. (*A. J. P.*, 1867, p. 386.) Soap plaster is considered discutient, and is sometimes used as an application to tumors, where a dressing is required. Somewhat softer in its character, the soap cerate,¹ formerly official, may be found useful.

Off. Prep.—*Emplastrum Calefaciens, Br.; Emplastrum Cantharidis, Br.*

Wax and Plaster, and, when these are melted, sprinkle in the Orris, and mix the whole together." By this process a good plaster may be prepared, rather too soft at first, but soon acquiring the proper consistence.

¹ *Ceratum Saponis, U. S. 1870. Soap Cerate.* (*Cérat de Savon, Fr.; Seifencerat, G.*)—"Take of Soap Plaster two *troycounces*; White Wax two *troycounces* and a half; Olive Oil four *troycounces*. Melt together the Plaster and Wax, add the Oil, and, after continuing the heat a short time, stir the mixture until cool." *U. S.* 1870.

Soap cerate is thought to be cooling and sedative, and is used in scrofulous swellings and other instances of chronic external inflammation.

EMULSA.

EMULSIONS

(e-mŭl'sa)

Emulsions, Fr.; Emulsiones, G.; Emulsiones, It., Sp.

Under this head are included in the *U. S. Pharmacopœia* liquid preparations in which oleaginous substances are suspended in aqueous fluids by the intervention of gum or other viscid matter. The preparations forming the present class of emulsions were termed Mixtures in earlier pharmacopœias, and it is to be regretted that under this indefinite term are still grouped liquids of many kinds; the separation of these into proper classes is only a question of time, and the introduction of this new class into the *Pharmacopœia* of 1890 marked the first step in the direction of greater accuracy in defining pharmaceutical preparations, and more system in classification. The object of emulsions is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines, and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect emulsions. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the aqueous vehicle is added. In the case of the liquid balsams and oils, if gum arabic is employed as the intermedium it should be previously brought to the state of mucilage of the consistence directed in the *U. S. Pharmacopœia*. When a fixed oil or balsam is to be made into an emulsion, the method most employed abroad is to add one part of gum to two or three of the oil, in a mortar, triturate until the mixture is complete, and then add at once twice as much water as gum used, and triturate rapidly until the oil is completely emulsified, then gradually add the remainder of the vehicle with constant trituration. Agitation in a bottle is sometimes substituted for trituration. The plan most largely used in this country is to make the emulsion with mucilage. Having a broad flat pestle and a mortar perfectly free from grease, put in a little mucilage, rub it around the mortar, add about half as much oil, triturate from the centre so as to emulsify this, then add more mucilage, then oil, and so on until the operation is completed. Care is required never to get the oil in excess of the mucilage. This plan seems to accord with the principle laid down by R. Rother (*Ch. Ph.*, 1872, p. 25), that the most perfect and rapid emulsifier is a perfect emulsion. The proportion of gum and water necessary to make a good emulsion with the fixed oils varies with the oil. Thus, while castor oil requires only two drachms of the gum and three drachms of water to the ounce, most other fixed oils require half their weight of gum, and a weight of water equal

to half that of the oil and gum united. These quantities being well rubbed together, any desirable amount of water may afterwards be gradually added, and will readily incorporate with the other ingredients. The white of egg has been frequently ordered by physicians as the suspending substance, but it is inferior for this purpose to the yolk, or to gum arabic. When the white is used it should be well beaten, and incorporated with the oleaginous or balsamic substances before the water is added. Quillaja, saponin, and other substances having similar properties have been proposed as emulsifying agents, but they are objectionable on account of their medicinal activity. Emulsifying agents should be inert.

EMULSUM AMYGDALÆ. U. S. (Br.)

EMULSION OF ALMOND [Milk of Almond]

(ē-mŭl'sŭm æ-myġ'dā-læ)

Mistura Amygdalæ, Br.; Almond Mixture; *Mistura Amygdalæ, U. S. P. 1880*; *Emulsio Amygdalæ, s. Amygdalarum, Emulsio Simplex*; Milk of Almonds; Simple Emulsion; *Emulsion d'Amande, Fr. Cod.*; *Lait d'Amande, Fr.*; *Mandelemulsion, Mandelmilch, G.*; *Emulsione di mandorle dolci, It.*; *Emulsion comun, Sp.*

* "Sweet Almond, sixty grammes [or 2 ounces av., 51 grains]; Acacia, in fine powder, ten grammes [or 154 grains]; Sugar, thirty grammes [or 1 ounce av., 25 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Having blanched the Almond, add the Acacia and Sugar, and beat them, in a mortar, until they are thoroughly mixed. Then rub the mass with nine hundred cubic centimeters [or 30 fluidounces] of water, at first very gradually added, until a uniform mixture results. Strain this into a graduated vessel, and wash the mortar and strainer with enough Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly. This emulsion should be freshly prepared when required." *U. S.*

"Compound Powder of Almonds, 2 ounces (Imperial) or 20 grammes; Distilled Water, 16 fl. ounces (Imp. meas.) or 160 cubic centimetres. Triturate the Powder with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water; strain through fine muslin." *Br.*

These preparations are essentially the same, the gum and sugar which enter into the U. S. formula directly being ingredients of the compound powder of almonds of the British. The gum arabic in these formulas is introduced not so much for its demulcent properties as to assist in the suspension of the insoluble ingredients of the almonds. The same formula will answer for the preparation of an emulsion of bitter almonds. The oleaginous matter of the almonds is suspended in the water

by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water, and with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when pure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The emulsion is not permanent.¹ Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. The preparation is closely analogous to milk in chemical relations and appearance. In warm weather it soon becomes sour.

Uses.—Emulsion of almond has a bland taste, and may be used as an agreeable, nutritive demulcent in catarrhal and dysenteric affections and irritation of the urinary passages. To be of service it must be freely employed. It is occasionally employed as an emollient lotion and as a vehicle for less agreeable medicines, but should not be used with any considerable quantity of tinctures, acidulous salts, or other acid substances.

Dose, two to eight fluidounces (60 to 240 Cc.).

EMULSUM ASAFETIDÆ. U. S.

EMULSION OF ASAFETIDA [Milk of Asafetida]

(ē-mŭl'sŭm æs-æ-fæt'idæ)

Asafetida Mixture; Mistura (Lac) Asafetidæ, Mistura Asafetida, U. S. P. 1880; *Mixture (Lait) d'Asafetida, Fr.*; *Asafetidaemulsion, Stinkasantmilch, G.*

* "Asafetida, in selected tears, forty grammes [or 1 ounce av., 180 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Rub the Asafetida, in a warmed mortar, with nine hundred cubic centimeters [or 30 fluidounces] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and rinse the mortar and strainer with enough Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly." *U. S.*

The present 4 per cent. official emulsion slightly exceeds in strength the mixture of the U. S. P. 1870, which contained but 3 per cent.

¹ *Concentrated Emulsion of Almonds.*—H. P. Reynolds prepares a permanent preparation which when mixed with three times its bulk of water, makes an emulsion which cannot be distinguished from the official, by using the following formula. Take of Sweet Almonds [blanched], Sugar, Glycerin ("C. P."), each, one ounce; Powdered Gum Arabic one drachm; Water two ounces. Rub to a uniform paste, strain through muslin, evaporate by a heat not exceeding 150° F. to the consistency of a fresh solid extract, flavor to suit.

of asafetida. This emulsion is less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable odor and taste are, however, objections, which induce a frequent preference for the last mentioned preparation. It is very often employed as an enema. From two to four fluidounces (60 to 120 Cc.) may be given by the rectum. D. Ackerman prepares a concentrated emulsion of asafetida, which will keep if excluded from the light, by using a mixture of three-fourths of pure water and one-fourth of diluted acetic acid as the menstruum. For cleaning mortars in which asafetida has been rubbed, he recommends solution of potassium hydroxide, followed by bitter almond water or paste, and soap and water. (*A. J. P.*, 1874, p. 268.)

Dose, one-half to one fluidounce (15 to 30 Cc.).

EMULSUM CHLOROFORMI. U. S.

EMULSION OF CHLOROFORM

(*ē-mŭl'sŭm chlō-rō-rf'ōr'mī*)

Chloroform Mixture; Emulsiō Chloroformi; Mistura Chloroformi, U. S. P. 1880; Emulsion de Chloroforme, *Fr.*; Chloroformemulsion, *G.*

* "Chloroform, *forty cubic centimeters* [or 1 fluidounce, 169 minims]; Expressed Oil of Almond, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Tragacanth, in very fine powder, *ten grammes* [or 154 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Introduce the Tragacanth into a perfectly dry bottle of sufficient capacity, add the Chloroform, and shake the bottle thoroughly, so that every part of the surface may become wetted. Then add about *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and incorporate it by vigorous shaking. Next add the Expressed Oil of Almond, in several portions, shaking after each addition, and when the Oil has been thoroughly emulsified, add enough Water, in divided portions, shaking after each addition, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.* The chloroform mixture of the U. S. P. 1880¹ was an excellent preparation; the present emulsion is not quite identical, there being no camphor in it. The expressed oil of almond renders the emulsion more permanent, and the proportion of chloroform is slightly less than in the U. S. P. 1880 chloroform mixture, being 4 per cent. instead of 5 per cent. as formerly. This emulsion affords an easy and

agreeable method of administering chloroform; the emulsion is permanent and does not separate on standing. The chloroform makes it keep long unchanged.

Dose, two to eight fluidrachms (7.5 to 30 Cc.).

EMULSUM OLEI MORRHUÆ. U. S.

EMULSION OF COD LIVER OIL

(*ē-mŭl'sŭm ō'lē-ī mōr'rhu-æ*)

Emulsion de Huile de Foie de Morue, *Fr.*; Leberthranemulsion, *G.*

* "Cod Liver Oil, *five hundred cubic centimeters* [or 16 fluidounces, 435 minims]; Acacia, in fine powder, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Syrup, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Oil of Gaultheria, *four cubic centimeters* [or 65 minims]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Rub the Acacia with the Cod Liver Oil in a dry mortar until uniformly mixed, then add at once *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water and triturate lightly and rapidly until a thick homogeneous emulsion is produced; to this add the Oil of Gaultheria and the Syrup, with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms], and mix thoroughly.

NOTE.—The Oil of Gaultheria may be replaced, if desired, by a suitable quantity of oil of bitter almond or other suitable flavoring." *U. S.* This emulsion was introduced into the U. S. P. (8th Rev.) for the purpose of affording a simple process for making a reasonably palatable and permanent preparation of cod liver oil. The continental method employed is best adapted for stock emulsions; to those who object to the taste of a combination of syrup and an oil with a fishy taste, the emulsion may be flavored with bruised celery seed and salt and then strained.

Dose, two to four fluidrachms (7.5 to 15 Cc.).

EMULSUM OLEI MORRHUÆ CUM HYPOPHOSPHITIBUS. U. S.

EMULSION OF COD LIVER OIL WITH HYPOPHOSPHITES

(*ē-mŭl'sŭm ō'lē-ī mōr'rhu-æ cŭm hŷ-po-phōs-phī'tj-bŭs*)

Emulsion de Huile de Foie de Morue avec les Hypophosphites de Chaux, de Soude et de Potasse, *Fr.*; Leberthranemulsion mit unterphosphorigsauren Salzen, *G.*

* "Cod Liver Oil, *five hundred cubic centimeters* [or 16 fluidounces, 435 minims]; Acacia, in fine powder, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Calcium Hypophosphite, *ten grammes* [or 154

¹ "Purified Chloroform, *eight parts* [or two fluidrachms]; Camphor, *two parts* [or forty-five grains]; Fresh Yolk of Egg, *ten parts* [or half a fluidounce]; Water, *eighty parts* [or four fluidounces], to make *one hundred parts* [or about five fluidounces]. Rub the Yolk of Egg in a mortar, first by itself, then with the Camphor, previously dissolved in the Chloroform, and lastly, with the Water, gradually added, so as to make a uniform mixture." *U. S.* 1880.

grains]; Potassium Hypophosphite, five grammes [or 77 grains]; Sodium Hypophosphite, five grammes [or 77 grains]; Syrup, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Oil of Gaultheria, four cubic centimeters [or 65 minims]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Rub the Acacia with the Cod Liver Oil in a dry mortar until uniformly mixed, then add at once two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Water and triturate lightly and rapidly until a thick, homogeneous emulsion is produced, add the Oil of Gaultheria and incorporate thoroughly; dissolve the Hypophosphites in one hundred cubic centimeters [or 3 fluidounces, 183 minims] of Water, mix the solution with the Syrup, and add the liquid gradually to the emulsion with continued trituration. Lastly, add enough Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms], and mix thoroughly.

NOTE.—The Oil of Gaultheria may be replaced, if desired, by a suitable quantity of oil of bitter almond or other suitable flavoring." U. S.

This process of the U. S. P. (8th Rev.), like that for the emulsion of cod liver oil, is intended to furnish a means of providing a uniform preparation which will take the place of many different proprietary emulsions on the market, for this can be prescribed by physicians without violating a code of ethics.

Dose, two to four fluidrachms (7.5 to 15 Cc.).

EMULSUM OLEI TEREBINTHINÆ.

U. S.

EMULSION OF OIL OF TURPENTINE

(ē-mŭl'sŭm ō'lē-I tēr-ē-bĭn'thĭ-næ)

Emulsion d'Essence de Térébenthine, Fr.; Terpen-tinēemulsion, G.

* "Rectified Oil of Turpentine, fifteen cubic centimeters [or 243 minims]; Expressed Oil of Almond, five cubic centimeters [or 81 minims]; Syrup, twenty-five cubic centimeters [or 406 minims]; Acacia, in fine powder, fifteen grammes [or 231 grains]; Water, a sufficient quantity, to make one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Introduce the Acacia into a perfectly dry bottle of sufficient capacity, add the Rectified Oil of Turpentine and the Expressed Oil of Almond and shake the bottle thoroughly. Then add about thirty cubic centimeters [or 1 fluidounce, 7 minims] of Water and incorporate it by vigorous shaking. When the Oil has been completely emulsified, add first the Syrup, in several portions, shaking after each addition, and then enough Water, in divided portions, shaking after each addition, to make the product measure one hundred cubic centimeters [or 3 fluidounces, 183 minims]." U. S.

The U. S. P. (8th Rev.) introduced this emulsion with the view of providing a simple and fairly permanent preparation. Rectified oil of turpentine should be used exclusively. The process is much like the one recommended by J. Winchell Forbes, and a mortar and pestle are not needed to produce a perfect emulsion.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

ERGOTA. U. S., Br.

ERGOT [Ergot of Rye, Spurred Rye]

(ĕr'gō-tă)

"The sclerotium of *Claviceps purpurea* (Fries) Tulasne (Fam. *Hypocreaceæ*), replacing the grain of rye, *Secale cereale* Linné (Fam. *Gramineæ*). Ergot should be moderately dried, and not exposed to a damp atmosphere. After being kept more than one year, it is unfit for use." U. S. "The sclerotium of *Claviceps purpurea*, Tulasne, originating in the ovary of *Secale cereale*, Linn." Br.

Secale Clavatum, Mater Secallis, Clavus Secalinus; Rye Smut, Mother of Rye, Cockspur Rye; Ergot de Seigle, Fr. Cod.; Ergot, Seigle Ergoté (noir), Blé Cornu, Fr.; *Secale Cornutum*, P. G.; Mutterkorn, Kornmutter, Hogenmutter, Zapfenkorn, Hungerkorn, G.; *Segala cornuta*, Grano speronato, It.; Cornezuelo de centeno, Sp.

In all the Gramineæ, or grass tribe, and in some of the Cyperacæ, the place of the seeds is sometimes occupied by a morbid growth which, from its resemblance to the spur of a cock, has received the name of *ergot*, adopted from the French. This product is most frequent in the rye, *Secale cereale*, and from that grain was adopted in the first edition of the U. S. Pharmacopœia, under the name of *secale cornutum*, or *spurred rye*. In the edition of 1840 the name was changed to *ergota*. It is probable that this morbid growth has similar properties from whatever plant derived, and the fact has been proved in relation to the ergot of wheat. (See A. J. M. S., N. S., xxxii. 479,¹ also Iowa Med. Journ., iv. 93.)

¹ Tulasne found that dissimilar sclerotia collected from twelve species of grasses, produced fructification identical with that of the ergot of rye, so that it is probable that many apparently dissimilar ergots are specifically identical, their appearance being modified by the species of grass which they inhabit. It is further probable that all ergots have medicinal properties which agree in character though not in intensity. The short thick ergot which gathers upon the wild rice of Minnesota, *Zizania aquatica*, L., has long been used as an abortifacient and oxytocic by the Indian women; while according to Parke, Davis and Co., the wild ergot growing on various species of *Agropyrum* and *Elymus* in the Western United States, is fully equal medicinally to the official plant. M. Leperdriel, Jr., affirms that the ergot of wheat is destitute of the poisonous properties of that of rye, and is less liable to change. Bentley of London, found that of two specimens, one of the ergot of rye, the other of wheat, which had been kept under similar circumstances for ten years, the former was quite destroyed, while the latter was apparently unchanged. Ergot is rarer in wheat than in rye, and in the head of the former there is generally but one and very rarely more than two of the diseased grains. It is produced usually in wheat in wet seasons, and on that side of the head most exposed to the damp-

Investigations of Tulasne have shown that ergot is not the diseased grain of the rye, but the *sclerotium* of a fungus, the *Claviceps purpurea*, Tulasne. This fungus has three stages in its life history. The development of the *sphacelia*, or first stage, commences with that of the pistil, which serves as a soil for it. The ovary of the rye consists of a cellular membrane of two coats, the outer of which has a thick parenchyma, white and gorged with juice; the inner is very delicate and green. The *sphacelia*, when it takes possession of the ovary, identifies itself with the outer parenchyma, and in some measure replaces it, being as it were borne by the inner membrane. It rapidly increases, taking the form of the ovary, and almost obliterating its cavity. The ovule is either entirely wanting, or may be seen, on a careful examination, in an imperfect form. For some time the parasite is represented entirely by the *sphacelia*, which is an oblong, fungous mass, almost homogeneous, soft and tender, marked on its surface by numerous sinuous furrows, and having within many irregular cavities, which, as well as the outer coat, are uniformly covered with linear parallel cells. From the summits of these peripheric cells, internal as well as external, issue oval capsules, from .005 to .007 Mm. in length, which spread upon neighboring objects, and especially the glumes of the flowers they inhabit. They are a kind of reproductive cells, called conidia, which are produced by many fungi long before the perfect plant is developed. Tulasne calls them "*spermatie*." In the early stage the *sphacelia* does not affect the top of the ovary; and the stigmas attached. The stamens often abort; but the filaments and anthers may sometimes be seen buried in the tissue of the *sphacelia*, and altered by its action. Sometimes the ovule is not completely aborted, but it is certainly never developed into a normal grain. In all ergotized plants the pistils and stigmas, when they remain, are often covered with a mouldiness, consisting of spores and entangled filaments, which end by covering the parts with an abundant ashy or sooty powder. This is a different fungus, and was confounded by Quekett with

the ergot plant. It is found as well in the non-ergotized as in the ergotized flowers, and in those of plants which do not bear ergot. At a somewhat advanced period of the development of the *sphacelia*, there exudes, especially from the summit, a very adhesive juice, which spreads over that structure, bearing along with it an immense number of the seedlets or "*spermaties*." This leaves on the surface when dry an oily appearance, and afterwards the spots, where it remains, become brownish or blackish. But this exudation does not appear until the *sphacelia* has ceased to constitute the whole plant.

At the base of the *sphacelia* is produced a compact body, violet-black without and white within, which is the ergot in a rudimentary state. With this commences the second stage in the development of the fungus. The young ergot is everywhere invested by the tissue of the *sphacelia* (which Tulasne calls also *spermagonia*, from its office); but, as it increases, it seems to be placed below the spermatophorous apparatus, and raises it steadily out of the floral bracts which concealed it, ending by supporting it wholly at its summit. Sometimes it carries with it the atrophied ovary, which still shows the hairs that crowned it, and some remains of the stigmas. It results that the ergot, which is technically the *sclerotium* of the fungus, remains for some time concealed in the *sphacelia*, so that this seems to constitute the whole plant; but, when the function belonging to this has been fulfilled, it begins to dry, and is much deformed. The ergot, on the contrary, increases in all directions, and soon appears above the glume. As it augments, the thin coating which it has received from the spermatophorous tissue, especially below, gradually becomes thinner, and seems to disappear, so that its surface, instead of being uniformly violet-black, is only here and there covered with the remains of the tissue, or with a deposit of the conidia or "*spermatie*." Nevertheless, the *sphacelia*, deformed, shrunken, and worn away by rains and other causes, remains long at the top of the ergot, along with the abortive ovary, etc., and may even continue to adhere when the ergot is detached from the plant. The time required for full development of the *sphacelia* and the ergot or *sclerotium* varies. In an example under the observation of Tulasne, at least a month elapsed after the appearance of the *sphacelia* before the growth was completed.

Ergot has absolutely nothing in common with normal grain. The anatomical structure and all the physical characters of ergot are those of the mushrooms, or rather of a sclerotic mycelium. The parenchyma, which is whitish, dry, and brittle, consists in all its parts of irregular, globular, or polyhedric thick-walled cells, intimately united, and filled with a limpid oil, but feebly colored by iodine. The superficial utricles, which alone are colored, have an outer wall thicker than the inner, and the color

ness. It is shorter and much thicker than the ergot of rye, being about half an inch long and three-quarters of an inch or more in circumference, and cleft into two or three divisions. In color and odor it resembles the spurred rye. (P. J., March and April, 1863.)

The ergot of oats is said to be of a black color, measuring from ten to twelve millimeters in length and three to four in thickness, and to have been used in Algeria as a substitute for rye ergot. (L. M. R., March, 1888.) The ergot of diss, an Algerian reed, *Ampelodesmos tenax*, has appeared in commerce to some extent. It is, when small, slightly curved, but when long (6 to 9 centimeters) it takes a spiral turn from right to left, the longitudinal furrows being present on the inner face. It is thinner, dryer, and more brittle than the ergot of rye, and has been used for the preparation of an ergotine or extract closely resembling the official one, but said to be of a clearer red or brown color. Lallemand asserts that the ergot of diss is twice as strong as the ergot of rye, and states that it is abundant and readily collected. It is also stated to be less hygroscopic and less apt to be attacked by acari than is the official article. (P. J., xvi. 684, 1886.)

of these is what gives its characteristic hue to ergot. Not the least trace of starch is to be detected. If ergot is planted in a suitable soil, evidences of germination are seen in about three months. Little globular prominences appear on its surface, which gradually enlarge, and raise themselves upon cylindrical stems, and finally become perfect pilei or fruiting fungi, producing elongated, rod-like spores in flask-shaped cavities which open by a little pore. These little fungi belong to the genus *Sphæria*. As they increase, the interior of the ergot becomes exhausted, by contributing to their growth. Falling to the ground, in its natural course, the ergot in the soil germinates, and produces pilei, the spores of which, carried up with the juices of rye, become lodged in the ovary, where they begin the course of life and progress which has been delineated. Different grains are probably infested with different species of *Claviceps*, but there is no reason to think that any other species is concerned in the product of any official variety of ergot. (*Annales des Sciences Naturelles*, 3e sér., xx. 5, 1853.) The ergot usually projects out of the glume or husk beyond the ordinary outline of the spike or ear. In some spikes the place of the seeds is wholly occupied by the ergot, in others only two or three spurs are observed. It is said to be much more energetic when collected before than after harvest. Rye has generally been thought to be most subject to the disease in poor and wet soils, and in rainy seasons, and intense heat succeeding continued rains has been said to favor its development, especially if these circumstances occur at the time the flower is forming. It is now, however, asserted that moisture has little or nothing to do with its production. It should not be collected until some days after it has begun to form, as, according to Bonjean, if gathered on the first day it does not possess the poisonous properties which it exhibits when taken on the sixth day. (See *P. J.*, Jan. 1842.) Ergot enters commerce chiefly from Russia, Germany, and Spain. Of the three varieties the Spanish ergot is considered the best, yielding usually from 13 to 15, sometimes as high as 18, per cent. of extractive. It is somewhat darker-colored, rather shorter, and more uniform than is the German ergot. An ergot of excellent quality has been sent from the Canary Islands to England.

Properties.—Ergot is in solid, brittle yet somewhat flexible grains, from a third of an inch to an inch and a half long, from half a line to three lines in thickness, cylindrical or obscurely triangular, tapering towards each end, obtuse at the extremities, usually curved like the spur of a cock, marked with one or two longitudinal furrows, often irregularly cracked or fissured, of a violet-brown color and often somewhat glaucous externally, yellowish-white or violet-white within, of an unpleasant odor when in mass, resembling that of putrid fish, and of a taste which is at first scarcely perceptible, but ultimately disagreeable and slightly acrid.

(29)

"Subcylindrical, obscurely three-angled, tapering toward both ends but obtuse, somewhat curved, 1.5 to 3 Cm. long and about 3 Mm. thick; externally purplish-black, longitudinally furrowed on each side, more conspicuously on the concave side; fracture short, pinkish or reddish-white; odor peculiar, heavy, increased by trituration with potassium hydroxide T.S.; taste disagreeable." *U. S.* Ergot yields its virtues to water and alcohol. The aqueous infusion or decoction is claret-colored, and has an acid reaction. It is precipitated by lead acetate and subacetate, silver nitrate, and tincture of galls, but affords with iodine no evidence of the presence of starch. Long boiling impairs the virtues of the medicine.

Assay.—The attempt to assay preparations of ergot by the action upon the comb of the domestic cock seems to us of doubtful utility, since it is at present uncertain whether the action of ergot upon the uterus and upon the blood vessels is due to the same principle or to several—it may be antagonistic—substances. Keller's method of chemical assay is based upon the fact that the vaso-constricting power of ergot is largely due to the alkaloid *cornutine*, which may be readily extracted with ether. Before extraction, however, it is necessary to remove the fixed oils, which can be accomplished by percolation with purified petroleum benzin, as follows:

25 Gm. of dried powdered ergot are percolated with petroleum benzin until a small portion of the percolate shows no residue upon evaporation. The ergot is then dried and shaken in a flask with 125 Cc. of ether for ten minutes, after which a mixture of 1 Gm. of calcined magnesia, with 20 Cc. of water, is added and the flask again agitated for thirty minutes. 100 Cc. of the ethereal liquid are now drawn off and filtered through cotton into a separator containing 25 Cc. of a 0.5 per cent. hydrochloric acid solution; after vigorous shaking the aqueous portion is decanted. This process should be repeated twice afterwards with 15 and 10 Cc. respectively of the acid solution. The collected acid liquids are then rendered alkaline with ammonia water and shaken out several times with ether, the ethereal solutions are collected in a tared flask and evaporated to dryness; the weight of the residue multiplied by 5 shows the percentage of alkaloid present, which should be about 0.2 per cent.

Ergot has been analyzed by Vauquelin, Winckler, Wiggers, Wright, Legrip, Wenzell, Tanret, Dragendorff, and several others. Wright supposed the virtues of ergot to reside in the fixed oil, which he therefore recommended as a substitute for the medicine. The *oil of ergot*, when obtained from grains recently collected, is, according to Wright, often quite free from color, but as usually prepared it is reddish brown. It has a disagreeable, somewhat acid taste, is lighter than water, and is soluble in alcohol and alkaline solutions. It is prepared by forming an ethereal tincture of ergot by the process of

displacement, and evaporating the ether with a gentle heat. It may be more cheaply prepared by substituting petroleum benzin for ether. Experience has shown that, though the oil thus prepared with ether may have produced effects analogous to those of ergot, they were to be ascribed rather to some principle extracted along with the oil by the menstruum than to the oil itself, for, when procured by expression, this has been found to be inactive, although Procter has ascertained that it contains a little *secalin*, one at least of the active principles of ergot, which may be separated from it by washing with acidulated water. According to T. R. Baker, the oil has a taste and odor similar to those of castor oil, with which it also agrees in ultimate composition, and yields analogous results in saponification. (*A. J. P.*, xxiv. 101-2.) T. C. Herrmann investigated specially the chemical constitution of the oil of ergot. As obtained by means of ether, it was brownish yellow, of an aromatic odor and acrid taste, viscid, of the sp. gr. 0.9249, and without the drying property. It consists of 22.703 per cent. of palmitic acid, 69.205 of oleic acid, and 8.091 of glycerin. (*N. R.*, 1872, p. 238; from *Buchner's Repertorium*, 1871, p. 283.) The sugar of ergot was found by Mitscherlich to be *mycose*, $C_{12}H_{22}O_{11}$. According to Wenzell (*A. J. P.*, May, 1864), ergot of rye contains two peculiar alkaloids, which he designated *ecboline* and *ergotine*, and claimed to be the active principles of the drug. The two bases of ergot are, according to Wenzell, combined with *ergotic acid*, the existence of which has been further admitted by Ganser. It is said to be a volatile body yielding crystallizable salts.

A crystallizable, colorless alkaloid, *ergotinine*, $C_{85}H_{140}N_4O_6$, which is probably identical with Wenzell's *ergotine*, was isolated (1877-78) by Tanret. He obtained it to the amount of 0.04 per cent., some amorphous *ergotine*, moreover, being present. The solutions of *ergotinine* turn greenish and red very soon; they are fluorescent. Sulphuric acid imparts to it a red, violet, and finally blue hue. The *ecboline* of Wenzell was named by Kobert *cornutine*. C. C. Keller asserts that *picrosclerotine*, *cornutine*, and Tanret's *ergotinine* are identical, and that ergot contains but one alkaloid which persists in it for one year unaltered. This alkaloid is crystalline, insoluble in water, soluble in alcohol and chloroform, slightly soluble in ether; by sulphuric acid it is colored violet blue. (*Chem. Ztg.*, 1894, 105; *Proc. A. Ph. A.*, 1895, 542.) C. Jakob (Ph. *Centralh.*, 1897, 58) believes that he has isolated from ergot three chemically different bodies, *chrysotoxin*, *secalintoxin*, and *sphacelotoxin*. All of these are, however, therapeutically similar. It is affirmed that *chrysotoxin* fully represents ergot pharmacologically, and retains its activity unaltered for years, whereas *sphacelotoxin* and *secalintoxin* do not.

Dragendorff and several of his pupils believe that they have isolated the following *amorphous* principles of the drug: 1, *sclerotic acid*, said to

be a very active substance, used chiefly in subcutaneous injections; about 4 per cent. of colorless acid may be obtained from good ergot of rye; 2, *scleromucin*, a mucilaginous matter which may be precipitated by alcohol from aqueous extracts of the drug; 3, *sclererythrin*, the red coloring matter probably allied to anthrachinon and the coloring substances of madder, chiefly to purpurin; 4, *scleroidin*, a bluish-black powder soluble in alkalies; 5, *fusco-sclerotinic acid*; 6, *picrosclerotine*, apparently a highly poisonous alkaloid; lastly, 7, *scleroxanthin*, $C_7H_7O_3 + H_2O$, and 8, *sclerocrystallin*, $C_7H_7O_3$, which have been obtained in crystals; their alcoholic solution is but little colored, yet assumes a violet hue on addition of ferric chloride.

Tanret also observed in ergot of rye a volatile *camphoraceous* substance.

For an improved process for making sclerotic acid, by Podwissotzky, see *N. R.*, 1883, p. 271. Voswinkel obtained from ergot a brown amorphous substance, which he proved by hydrolysis to yield *mannose*. The body is a hemi-cellulose, and the name *mannan* has been given to it. He states that Dragendorff's sclerotic acid and scleromucin are identical with mannan. (*Ph. Centralh.*, 1891, p. 531.)

Kobert (*Ph. Centralh.*, 1884, p. 607; *All. Das Mutterkorns*, Leipzig, 1884) found three physiologically active principles: 1st, *ergotic acid*, which he considers the principle constituent of the sclerotic acid of Dragendorff and Podwissotzky, and which is isolated by precipitation with ammoniacal lead subacetate; 2d, *sphacelic acid*, which can be isolated by taking advantage of the insolubility of the free acid in water and its solubility in alcohol; 3d, the alkaloid *cornutine*, which is not identical with the crystalline or with the amorphous *ergotinine* of Tanret; it is readily soluble in alcohol, and is obtained from an alkaline aqueous solution by agitation with ether. This alkaloid is said to be very poisonous. Kobert's conclusions have been questioned by Tanret (*P. J.*, 1885, p. 889), but the former reaffirms his statements and believes that *ergotinine* is worthless, and that the activity of fresh ergot is due to *sphacelic acid* and *cornutine* as above described: the important fact, however, is noted that these latter principles entirely lose their properties on keeping; he therefore proposes that they be made into pills and coated to protect them. (*A. Pharm.*, 1886, p. 597.) Kobert's process¹ for

¹ Exhaust the drug with water, acidulated with hydrochloric acid, neutralize the aqueous solution nearly with sodium carbonate, evaporate *in vacuo* at a very low temperature to a syrupy consistence, and treat with alcohol. Filter, distill off the alcohol carefully, and treat the nearly dry product with anhydrous ether, which removes any *ergotinine* present. After making the residue alkaline with sodium carbonate it is treated with acetic ether, and the solution shaken with water containing a little citric acid, which removes the *cornutine* in an almost pure state. This process is repeated, and it is finally precipitated from its acetic ether solution by anhydrous ether. Prepared in this way, *cornutine* will, if kept dry, and not exposed to light, remain unchanged. (The author kept some for three years.) (*J. B. P.*, 1891, p. 100.)

cornutine we append in a foot-note (page 450). For assay of ergot by A. R. L. Dohme, see *Proc. A. Ph. A.*, 1895, 263.

The odor of ergot is no doubt owing to the liberation of its volatile alkaloid, probably in consequence of a slow decomposition of the native salt. A method of detecting ergot in a mixed powder, rye flour for example, is thus afforded. If, on the addition of solution of potassium hydroxide, the odor of ergot be perceived, the presence of the drug is sufficiently proved.

Ergot, when perfectly dry and kept in well-stoppered bottles, will retain its virtues for a considerable time, but exposed to air and moisture it speedily undergoes chemical change and deteriorates. Gobley kept for more than ten years, perfectly sound, some ergot which he had selected from the year's harvest, carefully sifted, wiped with linen, then exposed to a heat of from 50° to 60° C. for three or four hours, and finally put into small boxes, holding each about 30 Gm. (a troyounce), previously heated with the ergot, and finally closed air tight with pitch. (*J. P. C.*, Mar. 1873, p. 216.) It is, moreover, apt to be attacked by a minute worm, which consumes the interior of the grain, leaving the exterior shell and an excrementitious powder. This insect is sometimes found in the ergot before removal from the plant. In the state of powder the medicine still more readily deteriorates, but Dragendorff believes that the decay is due to oxidization of the fatty principles of the ergot, and can be prevented by depriving the ergot of its oil before powdering. (*A. P. S.*, xxv.) This has since been confirmed by Zschiesing, who preserved ergot for two years, and Bombelon, who kept ergot in good condition for nine years, by previously removing the fixed oil with ether. (*Ph. Ztg.*, No. 49, p. 51; *A. J. P.*, 1881, p. 457.) It is best, as a rule, to renew it every year or two. M. Viel recommends that it should be well dried at a gentle heat, and incorporated with double its weight of loaf sugar, by means of which, if protected from moisture, it will retain its virtues for many years. According to Zanon, the same result is obtained by stratifying it with well washed and perfectly dried sand, in a bottle from which air and light are excluded. Camphor and powdered benzoin are said to prevent injury from worms. Aymoiner immerses fresh ergot in an ethereal solution of tolu, dries it, and preserves in tightly closed bottles.

Uses.—Ergot can scarcely be considered as a poison, since an ounce of the fluidextract rarely produces, except in the pregnant, any obvious symptoms unless it be nausea, and we have administered the same preparation in daily dose of three ounces continuously for several weeks without producing distinct symptoms. Large doses are liable, it is true, to produce abortion in pregnant women, but even this result is uncertain, and we know of but one instance of fatal poisoning by it unless the

death was produced by the abortion. The symptoms of the recorded cases of poisoning have been paleness, and, as most characteristic, an especial coldness of the surface, partial paralysis with numbness and tingling in the limbs, feebleness of the pulse, restlessness, and finally stupor or delirium.

In the fatal case narrated by Pratschke, uneasiness in the head, oppression of stomach, diarrhoea, urgent thirst, burning pains in the feet, tetanic spasms, violent convulsions, and death ensued upon eating freely of ergotized grain. (*London Med. Gaz.*, Oct. 1850, p. 579.) The long continued and free use of ergot is highly dangerous, even when no immediate effects are perceptible. Fatal epidemics in different parts of the continent of Europe, particularly in certain provinces of France, have long been ascribed to the use of bread made from rye contaminated with this fungus.¹ Dry gangrene, typhus fever, and disorder of the nervous system attended with convulsions, are the forms of disease which have followed the use of this unwholesome food. It is true that ergot has been denied to be the cause, but accurate investigations made by competent men upon the spot where the epidemics have prevailed, together with experiments upon inferior animals,² leave no room for reasonable doubt that at least the gangrenous affection alluded to has resulted from it.

Upon the lower animals ergot acts as upon man. Besides its influence upon the uterus, the most important physiological action of the drug is upon the vasomotor nervous system. It has been abundantly proved that in full therapeutic dose it raises remarkably the arterial pressure by producing a general vasomotor spasm. This spasm is almost certainly the result of a stimulation of the vasomotor nerve centres, but there are still some authorities who believe that the drug acts peripherally upon the muscular coats of the vessels or upon the nerves connected therewith.

On the continent of Europe, in Germany, France, and Italy, ergot has long been empirically employed by midwives for promoting the contraction of the uterus, and its German name of *mutterkorn* implies a popular acquaintance with its peculiar powers. But the attention of the medical profession was first called to it by Stearns of Saratoga County, N. Y. (*New York Medical Repository*, 1807.) In its operation upon the pregnant uterus, it produces a constant unremitting contraction and rigidity, rather than that alternation of spasmodic effort and relaxation which is observable in the natural process of labor. Hence, unless the os uteri

¹ Hofmann states that one-tenth per cent. of ergot can be detected in bread by macerating 30 grains of coarsely grated bread in 40 grains of ether and 20 drops of diluted sulphuric acid for 24 hours, straining, shaking with solution of sodium bicarbonate and allowing to stand, when the solution separates and is of a violet color. (See also *N. R.*, 1883.)

² An epidemic among sheep was caused by eating ergotized grain. (See *P. J.*, x. 195.)

and external parts are sufficiently relaxed, the medicine is likely to produce injury to the fetus by the incessant pressure which it maintains, and the death of the child is thought not unfrequently to have resulted from its injudicious employment. The cases to which it is thought to be especially adapted are those of lingering labor, when the os uteri is sufficiently dilated and the external parts sufficiently relaxed, when no mechanical impediment is offered to the passage of the child, and the delay is ascribable solely to want of energy in the uterus. Other cases are those in which the death of the fetus has been ascertained, and when great exhaustion or dangerous constitutional irritation imperiously calls for speedy delivery. The medicine may also be given to promote the expulsion of the placenta, to restrain inordinate hemorrhage after delivery, and to hasten the discharge of the fetus in protracted cases of abortion. In women subject to dangerous flooding, a dose of ergot given immediately before delivery is said to be very beneficial in its effects.

Ergot is also much used to cause the expulsion of coagula of blood, polypi, and hydatids from the uterine cavity, and even a number of successful cases of its employment for the destruction by strangulation of fibroid tumors of the uterus have been reported. In uterine hemorrhage, unconnected with pregnancy, the medicine is very useful, and it is probably the most used and most efficient of all remedies in pulmonary and other similar internal hemorrhages. Its action in these cases is no doubt the result of the contracting power it has over the smaller vessels. This action of ergot upon the blood vessels suggests its employment in those cases in which there is local or general dilatation of the blood vessels. It has been used in pulmonary congestion with apparent good results, and it has been highly lauded in the first stages of pneumonia by several clinicians, especially by J. E. Kelly (*Med. Register*, 1887, vol. x.), as giving immediate relief when injected hypodermically in low forms of pulmonary hyperemia such as occur in typhoid fevers. It will probably also be found of service as a vasomotor stimulant in surgical shock, and has been much used against cerebral congestion, in spinal congestion, in colliquative sweats, and in diabetes insipidus. In apoplexy, owing to its pronounced tendency to increase the blood pressure, it must be given with the greatest caution if at all. The best preparation of ergot for internal administration, except when an immediate influence is desired, is the official solid extract given in capsules. The fluidextract is perhaps absorbed a little more quickly, but it is much more apt to sicken the stomach. The dose of solid extract is 5 to 30 grains (0.32 to 2.0 Gm.); of the fluidextract, half a fluidrachm to two fluidrachms (1.8 to 7.5 Ce.). In hemorrhoids, and in varicose veins of the leg, it has been injected into the diseased tissue with success, but probably acts only by producing a severe local inflammation.

Under the name of *ergotine*, usually with the name of the maker attached, a number of purified extracts of ergot are upon the market. They may be used in doses of from 5 to 10 gr. (0.32 to 0.65 Gm.), but have no advantage over the official preparations. *Bonjean's ergotine* is made by exhausting ergot with water, evaporating to the consistence of syrup, precipitating the albumen, gum, etc., by a large excess of alcohol, decanting the clear liquid, and evaporating to the consistence of a soft extract. When promptness and certainty of action are required, ergot may be used hypodermically. Solutions of extract of ergot are very prone to undergo speedy decomposition, and, as such altered solutions are very irritating, it is important that solutions for hypodermic use be made freshly, especially as the experiments of Engelmann (*D. M. W.*, Sept. 30, 1886) have shown that the addition of ordinary antiseptic agents to such solutions, unless in very large amount, simply delays decomposition, and that the changes may be far advanced although the preparations seem to the eye unaltered. Notwithstanding all possible precautions, the hypodermic injections of ergot have a tendency to produce local inflammations and abscesses, but the danger may be reduced to a minimum by absolute obedience to the following directions: Extract of ergot, five grains, should be dissolved in twenty minims of recently boiled water, and two or three drops of glycerin and half a drop of phenol be added. This solution should be filtered to remove any solid particles, and then at once be thrown deeply into the cellular tissues.

Dujardin-Beaumetz gives the dose of Tanret's crystallized ergotine for hypodermic use as 5 milligrammes (seven-hundredths of a grain). (*B. G. T.*, xciv. 236.) Sclerotic acid does not represent ergot, as was, so far as concerns the commercial article, shown by experiments made in the laboratory of the University of Pennsylvania; indeed, the research of Nikitin, who claims that it is the active principle, affords abundant evidence that it is not so. (*L. M. R.*, 1879, p. 21.)

Dose, of ergot, fifteen to sixty grains (1 to 3.9 Gm.).

Off. Prep.—Extractum Ergotæ, U. S., Br.; Fluidextractum Ergotæ, U. S. (Br.); Infusum Ergotæ, Br.; Injectio Ergotæ Hypodermica, Br. (from extract); Tinctura Ergotæ Ammoniata, Br.; Vinum Ergotæ, U. S. (from fluidextract).

ERIODICTYON. U. S.

ERIODICTYON [*Yerba Santa*]

(ēr-i-q-dīc'ty-ŏn)

"The dried leaves of *Eriodictyon californicum* (Hooker and Arnott) Greene (Fam. *Hydrophyllaceæ*)." U. S.

Mountain Balm, Consumptive's Weed, Bear's Weed, Gum Bush.

Eriodictyon [*Eriodictyum*] *californicum* (Hook. and Arn.), Greene (*E. glutinosum*, Benth.), is a low evergreen shrub growing abundantly upon dry hills in California. It is glabrous, resinous to the feeling, with lanceolate leaves from three to six inches long, irregularly more or less serrate, sometimes entire, whitened beneath, between the reticulations, by a minute and close tomentum, above glabrous. The corolla is half an inch long, tubular funnel-form; the calyx is about one-sixth of an inch long, and sparsely hirsute. The leaf structure has been studied by F. W. Ritter. (See *A. J. P.*, 1895, 565.)

E. tomentosum, which grows often along with *E. californicum*, especially in the southern part of California, is readily distinguished by its dense coat of short villous hairs, whitish or rusty-colored with age. It is also a larger shrub than *E. californicum*, has its corolla somewhat salver-form, and its leaves oblong or oval, and obtuse.

Properties.—The leaves of *eriodictyon* have already been sufficiently described, but they are further characterized by the U. S. Pharmacopœia as "usually occurring in fragments; entire leaf oblong-lanceolate, 5 to 15 Cm. long and 1 to 3 Cm. broad, acute at the apex, narrowed below into a short, broad petiole, the margin more or less incurved, entire or irregularly serrate, or crenate-dentate; upper surface yellowish-green, smooth, covered with a brownish resin; lower surface whitish or yellowish-white, conspicuously reticulated and densely tomentose; brittle, but flexible in a damp and warm atmosphere; odor somewhat aromatic; taste balsamic and sweetish." U. S. H. S. Wellcome (*Pharm.*, 1876, p. 73) found the drug to contain two aromatic resins, while an aqueous infusion of leaves which had been exhausted by alcohol yielded an intensely bitter extract. According to the analysis of Chas. Mohr (*A. J. P.*, 1879, 549), it contains tannic acid and 8 per cent. of an acrid, bitter resin, upon which its activity is believed to depend, also a minute quantity of volatile oil. R. Rother describes (*A. J. P.*, 1887, p. 225) an acid resin which forms with bases quite soluble salts. The acid resin was obtained at the conclusion of the spontaneous volatilization of the several solvents as a green-yellow transparent mass. Thal (*Ph. Z. R.*, 1883, p. 209) showed the presence of *ericolin*, $C_{34}H_{56}O_{21}$.

Uses.—*Eriodictyon* has long been used in California as a bitter tonic, and also as a stimulant balsamic expectorant. There is considerable testimony to its usefulness in *asthma*, *chronic bronchitis*, and allied conditions; also in chronic inflammation of the genito-urinary tract. Attention has been called by Kier to its remarkable power of disguising the taste of quinine. It is best exhibited in the form of the official fluidextract, the dose of which is one-half to one drachm (1.8 to 3.75 Gm.); a solid extract has been made, which may be given in doses of from five to fifteen grains (0.32 to 1.0

Gm.). In cases of asthma, *eriodictyon* is often used by smoking. The aromatic syrup is well adapted as a vehicle for quinine.

Dose, fifteen to sixty grains (1.0 to 3.9 Gm.).

Off. Prep.—Fluidextractum *Eriodictyi*, U. S.

EUCALYPTI GUMMI. Br.

EUCALYPTUS GUM

(eū-ca-lyp'ti gūm'mī)

Australian or Eucalyptus Kino; Red Gum.

"A ruby-colored exudation, or so-called red gum, from the bark of *Eucalyptus rostrata*, *Schlecht*, and some other species. Imported from Australia." Br.

A kino-like exudation is obtained in Australia from various species of *Eucalyptus*, but the commercial is chiefly yielded by *E. rostrata*, which occurs over a wide area along water-courses in Australia and New South Wales. It is a large, gregarious tree, with almost linear-pointed leaves and shining bark, and is especially characterized by the long beak upon the operculum of its seed vessel. The gum is obtained by cutting the tree, inserting a piece of bent tin, and catching the red, thick liquid in a vessel. The average yield is said to be about one quart per tree. In a few days the liquid hardens into a kino-like mass.

Red gum occurs in commerce in grains or small masses of a purplish-red, ruby-red, or garnet color, closely resembling ordinary kino, but somewhat more brilliant, with a distinctly bitterish taste, tough, and adhering to the teeth. It does not equal kino in astringency. From 80 to 90 per cent. of it is soluble in cold water, forming a neutral solution. It is almost entirely soluble in alcohol (90 per cent.). For further description, see "Australian Kino," under *Kino*. In the analyses made by J. H. Maiden, red gum yielded about 4.5 per cent. of tannic acid. (*A. J. P.*, 1897.) It is used for *diarrhœas* of relaxation, and other affections for which kino has been employed, and is also largely employed as the basis of lozenges and gargles.

Dose, from two to ten grains (0.13 to 0.65 Gm.).

Off. Prep.—Trochiscus *Eucalypti Gummi*, Br.

EUCALYPTOL. U. S.

EUCALYPTOL [Cineol]

(eū-ca-lyp'tōl)

$C_{10}H_{18}O = 152.98$

"An organic oxide (cineol), obtained from the volatile oil of *Eucalyptus Globulus* Labillardière (Fam. *Myrtaceæ*), and from other sources. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

Eucalyptol, Fr. *Cod.*; Cinéol, Terpane, Cajeputol, Fr.; Terpan, G.; Eucalptol, Sp.

This was a new official liquid of the U. S. P. 1890. In the distillation of eucalyptus leaves, the portion which comes over between 170° C. (338° F.) and 178° C. (352.4° F.) is set aside as crude eucalyptol. To obtain it pure a redistillation from potassium hydroxide or calcium chloride is necessary. It is very liquid, nearly colorless, with a strong, aromatic, camphoraceous odor, is slightly soluble in water, but very freely soluble in alcohol. Nitric acid produces with it a crystallizable acid; by the action of phosphoric anhydride (*J. P. C.*, 4e sér., xii. 204) it is converted into *eucalyptene*, $C_{10}H_{18}$, a substance allied to cymene, and *eucalyptolen*.

C. Jahns (*A. J. P.*, 1885, p. 237) gave the formula $C_{10}H_{18}O$ to eucalyptol, and showed it to be identical with cajuputol, or, as it is now generally known, *cincol*. Wallach (*Ann. Ch. Ph.*, 248, pp. 278 to 283) showed that the oil from *E. Globulus* contained cineol (*eucalyptol*) and *dextro-pinene*, while that from *E. amygdalina*, Labill., contained cineol and *lavo-phellandrene*. (See *Eucalyptus*.)

The U. S. Pharmacopœia describes it as follows: "A colorless liquid, having a characteristic, aromatic, and distinctly camphoraceous odor, and a pungent, spicy, and cooling taste. Specific gravity: 0.925 at 25° C. (77° F.). Soluble in all proportions in alcohol. Boiling point: 176° to 177° C. (348.8° to 350.6° F.). Eucalyptol is optically inactive (distinction from the oil of *eucalyptus* and many other volatile oils). When exposed to a temperature somewhat below 0° C. (32° F.) it solidifies to a mass of colorless, needle-shaped crystals, which liquefy at -1° C. (30.2° F.). If 1 Cc. of Eucalyptol be placed in a freezing mixture and an equal volume of phosphoric acid be gradually added, a solid white crystalline mass of cineolphosphoric acid should result, and if warm water be then added the cineol will separate. If 5 Cc. of Eucalyptol be shaken with 5 Cc. of sodium hydroxide T.S., it should not diminish in volume. Its alcoholic solution should be neutral to litmus paper, and if to 5 Cc. of this solution a drop of ferric chloride T.S. be added, there should not be produced a brownish or violet color (absence of *phenols*)." U. S.

Uses.—Eucalyptol has been used with good results, instead of oil of eucalyptus, as a stimulant expectorant in *catarrhal pneumonia*, chronic *bronchitis*, *bronchorrhea*, and other catarrhal conditions of the respiratory mucous membrane. Its vapor volatilized with steam in an inhaling apparatus is efficient. It has also been employed in chronic inflammation of the *genito-urinary* mucous membrane, and locally as an antiseptic dressing to *ulcers*, and as a counter-irritant in *neuralgia* and *rheumatism*.

Dose, five to ten minims (0.3 to 0.6 Cc.) four to six times a day, best administered in capsules. Its solution in fatty oil has been used hypodermically.

Off. Prep.—Liquor Antisepticus, U. S.

EUCALYPTUS. U. S.

EUCALYPTUS

(eū-qa-lŭp'tūs)

"The dried leaves of *Eucalyptus Globulus* Labillardière (Fam. *Myrtaceæ*), collected from the older parts of the tree." U. S.

Blue Gum-tree Leaves, Australian Fever-tree Leaves, *Eucalyptus* Leaves; *Eucalyptus*, *Fr. Cod.*; Feuilles d'*Eucalyptus*, *Fr.*; *Eucalyptusblätter*, *G.*; Eucalitto, *It.*; Eucalipto (Hoja de), *Sp.*

The genus *Eucalyptus* is composed of evergreens, most of them large trees, principally known as *Gum trees*, *Woolly butts*, *Iron barks*, etc., natives of Australia and Tasmania, forming, it is stated, about three-fourths of the whole vegetation of those countries. At least one hundred and forty species have been described, but there seems to be much obscurity in regard to the specific distinction of the various forms.¹

Most of the species do not require excessive heat for their perfecting, and some of them are able to resist moderate frosts. Over forty species are being grown successfully in the United States, and in the neighborhood of Los Angeles and other points in California a pure oil is said to be commercially produced. On account of the rapidity of their growth and the hardness and indestructibility of their timber, many of the species are very valuable for economic purposes. A number of the species are said to be cultivated in the Southwest as a source of honey. (See *Bulletin No. 35 of the U. S. Bureau of Forestry*.)

E. Globulus, Labill.; *B. & T.* ii. 109.—The young operculum conical, the length of the four-sided cupule, the adult depressed and mucronate in the middle; axillary peduncles very short, one-flowered; leaves alternate, lanceolate, subfalcate.

According to Albert Schneider, the tree *E. Globulus* produces two distinct leaf forms. Of these the earlier are comparatively thin, rather large, ovate and cordate at the base, and are almost free from medicinal properties, while the so-called isolated leaves, which appear later, are thick, sickle-shaped, pointed, and not cordate at the base. (*P. J.*, lix. 191.)

This is one of the largest known trees, attaining sometimes a height of 300 or even 350 feet, with a smooth, ash-colored bark; leaves a foot in length, and varying, according to age, from a glaucous white to a bluish-green color; and large pinkish-white axillary flowers, sometimes single, sometimes in clusters. Although its wood is very resinous, hard, and durable, the tree is remarkable for the rapidity of its growth, reaching, under favorable circumstances, fifty feet of height in five or six years. It flourishes best in valleys having a rich, moist soil, and has very

¹ See Bentham, *Flora Australensis*; Baron F. von Mueller's *Eucalyptographia*, 1879 to 1884. Baker and Smith (*A Research on the Eucalypts*, Sydney, 1902), arrange the species in seven different groups, according to the chemical characteristics of the oils which they produce.

It is stated that the leaves of the *E. rebaudianum*, of Paraguay, are used in that country in place of sugar, which they exceed in sweetening power.

largely been naturalized in semi-tropical countries, partly on account of its economic value, but chiefly because of the reputation it enjoys as a means of overcoming malaria. Its sanitary powers appear to be established, numerous notoriously miasmatic stations and districts having been rendered healthful by its growth. It is probable that the destruction of the miasma is due not so much to emanations from the tree as to the fact that it evaporates water so rapidly from its innumerable large leaves as to drain the swamps and marshes in which it is planted. It is possible, however, that the large amount of volatile oil which must escape from it has some effect, and it is even affirmed (*A. J. P.*, 1875, p. 423) that the parasitic phylloxera will not attack grape-vines growing near it.

The eucalyptus oil of commerce is, indeed, composed chiefly of the oils of *E. amygdalina* and *E. dumosa*, which yield a very much larger product than does the official species. The oils of *E. piperita* and *E. hamastoma* have a peppermint odor, and that of *E. citriodora* a citron-like odor, while the oil of *E. staigeriana* exactly resembles the oil of verbenia; it is probable that these oils will come into commerce for the purposes of the perfumer.

Properties.—The leaves are the official portion of the plant and are officially described as follows: "Petiole twisted, 2 to 3 Cm. long; blade lanceolately scythe-shaped, from 15 to 30 Cm. long, 2 to 4 Cm. broad, tapering above, rounded or very abruptly contracted at the oblique base, coriaceous, pale green, pellucid-punctate; venation inconspicuous, anastomosing near the entire margin; odor aromatic and somewhat camphoraceous; taste aromatic, bitter, and cooling." *U. S.*

In March, 1870, Cloez (*J. P. C.*, 4e sér., xii. 201) reported an elaborate chemical study of the eucalyptus leaves, and his results have been substantially confirmed by Debray (*De l'Eucalyptus Globulus*, Paris, 1872), Rabuteau (*Mém. de l'Académie*, Nov. 1872), and Broughton (*P. J.*, 3d ser., iii. 463). Cloez found, besides chlorophyll, resin, tannin, and inert substances, an essential oil, upon which the virtues of the drug appear to depend. Of this oil the fresh leaves afforded 2.75 parts per hundred, the recently dried leaves 6 parts; leaves which had been kept some time yielded a much smaller percentage. In the distillation, the oil for a time comes over freely at from 170° C. (338° F.) to 178° C. (352.4° F.); subsequently another portion of oil distils at 188° C. (370.4° F.) to 190° C. (374° F.), and finally a very minute portion does not volatilize until the temperature reaches 200° C. (392° F.). Cloez believes the oil to be composed of two camphors, differing in their volatility. The bulk of the oil yielded is the portion first distilled; to this Cloez has given the name of *eucalyptol*, or, as it is now also called, *cineol*, $C_{10}H_{18}O$. (See previous article.) Gildemeister and Hoffmann (*Aetherische Oele*, 1899, p. 690) divide the eucalyptus oils into 5 groups according to their con-

stituents, viz: Group 1, Cineol (or Eucalyptol) containing oils, of which group *Eucalyptus Globulus* is the most important; Group 2, Citronellal containing oils, of which group *Eucalyptus maculata* is the most important; Group 3, Citral containing oils, of which *E. staigeriana*, F. von Muell., is the typical example; Group 4, Peppermint smelling oils, of which *Eucalyptus piperita* is an example; and Group 5, Less known oils of varying odor.

Schimmel & Co. (*Semi-Annual Report*, April, 1897) gave a list of some fifteen varieties of eucalyptus oils from the different Eucalyptus species. In their report for October, 1904, they give the sources and state the properties and components of 109 different eucalyptus oils obtained by them from Baker and Smith, Curators of the Technological Museum of Sydney, N. S. W.

According to Duquesnel, the oil of eucalyptus is adulterated—with alcohol, to be detected by means of fuchsin, which is insoluble in the pure oil but soluble in that containing even a very small percentage of alcohol; with fixed oil, to be detected by boiling with water, when the fixed oil remains on the surface; with essential oil of copaiba or turpentine, to be detected by means of the boiling point, that of eucalyptol being 170° C. (338° F.), that of oil of turpentine 155° C. (311° F.), that of oil of copaiba 260° C. (500° F.). (*J. P. C.*, 4e sér., xvi. 45.)

Uses.—Whatever medicinal virtues eucalyptus possesses beyond astringency reside in the volatile oil. This when applied locally acts as a powerful irritant. When taken internally in doses of from 20 to 30 drops, it causes increased rapidity of pulse and general excitation, with restlessness and increased veneral appetite, usually followed by a feeling of calmness and repose, ending in sleep. In some cases, disturbance of the bowels, fever, constitutional disturbance, and even symptoms of cerebral congestion have been produced. In animals small doses produce the same effect as in man, and after large doses symptoms of general depression are manifested by falling of the arterial pressure, progressive diminution of temperature, muscular weakness deepening into paralysis, loss of sensibility, irregular respiration, and finally death from failure of respiration. Upon man, when taken in sufficient quantity, the oil exerts a similar influence. In a case noted by Gimbert, 80 drops of the oil produced in an old man a feeling of great internal heat, followed by almost complete loss of power and of feeling in the limbs, and after 75 drops Binz noted somewhat similar phenomena. The palsy produced by toxic doses is due to a direct action upon the spinal cord. Taken internally, it is eliminated by the breath, to which it imparts its odor, and also, in a condition of oxidation, by the kidneys, to the secretion of which it gives a strong odor of violets. Gimbert found that in rabbits it augmented to a marvelous extent the excretion of urea. The reputation once enjoyed

by the oil of eucalyptus as being a valuable antiperiodic, antispasmodic and antineuralgic was not well founded. Its chief importance in practical medicine is as a stimulant expectorant in advanced stages of *acute bronchitis* and in *chronic bronchitis*. It has been especially praised in *asthma*, given internally or preferably by inhalation by means of cigarettes, which may be made by rolling up the dried leaves, or the vapor from boiling water containing the oil may be inhaled. It has also been used in chronic *genito-urinary inflammations* and as a local stimulant, antiseptic application, in *skin diseases*. Although, as shown by Binz and Gimbert, it acts distinctly upon low forms of life, it is very rarely if ever used as an antiseptic. Various formulas have been published for tinctures, fluidextracts, etc., but either the oil or eucalyptol should be preferred.

Dose, of eucalyptus, ten to thirty grains (0.65 to 2 Gm.); of the oil, five to ten minims (0.3 to 0.6 Cc.).

Off. Prep.—Fluidextractum Eucalypti, *U. S.*

EUGENOL. U. S.

EUGENOL [Synthetic Oil of Cloves]

(eū'gē-nōl)

"An unsaturated, aromatic phenol [$\text{C}_6\text{H}_5(\text{O} \text{H})(\text{OCH}_3).\text{C}_5\text{H}_5$ 4:3:1], obtained from Oil of Cloves and other sources. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Allylguaiacol, Allylmethylpyrocatechol; Eugenol, *Fr.*; Oleum Caryophyllorum, *P. G.*; Eugenol, *G.*

Eugenol is extracted on a large scale from oil of cloves and utilized as the starting point in the manufacture of artificial vanillin (see *Vanillinum*). It is officially described as "a colorless, or pale yellow, thin liquid, having a strongly aromatic odor of cloves, and a pungent and spicy taste. Exposure to air causes it to become darker and thicker. Specific gravity: 1.066 to 1.068 at 25° C. (77° F.). Eugenol is miscible with alcohol in all proportions, and should be soluble in 2 parts of 70 percent. alcohol. Boiling point: 251° to 253° C. (483.8° to 487.4° F.). It is optically inactive. When 1 part of Eugenol is dissolved in 12 parts of sodium hydroxide T.S. and 18 parts of water are added, a clear solution should result, which becomes turbid when exposed to the air. A mixture of 1 part of Eugenol and 20 parts of hot water should redden litmus paper very slightly. Five Cc. of the cold, clear filtrate from this mixture, upon the addition of 1 drop of ferric chloride T.S., should show a transient grayish-green color, but not a blue or violet color (absence of phenol)." *U. S.*

Uses.—Eugenol may be used for the same purposes as oil of cloves.

Dose, two to five minims (0.12 to 0.3 Cc.).

EUONYMUS. U. S. (Br.)

EUONYMUS [Wahoo]

(eū-ōn'y-mūs)

"The dried bark of the root of *Euonymus atropurpureus* Jacquin (Fam. *Celastraceae*)." *U. S.* "The dried root bark of *Euonymus atropurpureus*, *Jacquin*." *Br.*

Euonymi Cortex, *Br.*; *Euonymus Bark*; *Cortex Euonymi*; *American, Indian Arrow-wood*; *Ecorce d'Euonymus*, *Fr. Cod.*; *Spindlebaum*, *Pfaffenhütchen*, *Spillbaumrinde*, *G.*

Euonymus atropurpureus, Willd., *Sp. Plant.* i. 1132; *Gray's Manual*, p. 81; figured in *Griffith's Med. Bot.*, p. 219.—The plant has been named variously *wahoo*, *spindle-tree*, and *burning-bush*. It is a tall, erect shrub, with quadrangular branchlets, and opposite, petiolate, oval-oblong, pointed, serrate leaves. The flowers, which stand in loose cymes on axillary peduncles, are small and dark purple, with sepals and petals commonly in fours. The capsule or pod is smooth and deeply lobed. The plant is indigenous, growing throughout the Northern and Western States, and sometimes cultivated for the beauty of its crimson fruit.

The plants belonging to this genus are shrubs or small trees, presenting in the autumn a striking appearance from the rich red color of their fruit, which has obtained for them the name of *burning-bush*. *E. americanus* and *E. europæus* have been cultivated in gardens as ornamental plants. Two or more of the species have been used in medicine. Their properties are probably similar, if not identical. Grundner, who experimented with the fruit of *E. europæus*, found it to have no other effect than that of a diuretic. (*Ph. Cb.*, 1847, p. 873.) An oil expressed from the seeds is used in Europe for the destruction of vermin in the hair, and sometimes also as an application to old sores. (*Ibid.*, 1851, p. 641.) Griffith says that the seeds of this and other species are purgative and emetic, and that the leaves are poisonous to sheep and other animals feeding on them. He states also that the inner bark of *E. tingens* is beautifully yellow, and used in India for dyeing, and in diseases of the eye. (*Med. Bot.*, p. 220.) It is probable that much of the wahoo of our drug stores has been obtained from *E. americanus*, which is distinguished from *E. atropurpureus* by its rough, warty, depressed pods, and almost sessile, thickish leaves. This bark was introduced into the last British Pharmacopœia in the supplement.

Properties.—The dried bark is in thin pieces, whitish with a darker grayish epidermis, brittle, of a feeble, peculiar, not disagreeable odor, and a bitterish slightly sweetish taste, and somewhat pungent after-taste. "In quilled or curved pieces, 3 to 7 Cm. long and 0.5 to 5 Mm. thick; outer surface ashy or pale brownish-gray, with small, dark, scaly patches of soft cork; inner surface whitish or light brown, smooth; fracture short, whitish, with projecting, silky, modified

bast fibres; odor distinct; taste sweetish, bitter and somewhat acrid." *U. S.* It imparts its virtues to water and alcohol. Analyzed by Wm. T. Wenzell, it was found to contain a bitter principle which he named *euonymin*, asparagin, a soft resin, a crystallizable resin, a yellow resin, a brown resin, fixed oil, wax, starch, albumen, glucose, pectin, and various salts of organic and inorganic acids. *Euonymin* was obtained by agitating with chloroform a tincture made with diluted alcohol, separating the chloroformic solution and allowing it to evaporate spontaneously, treating the residue with ether, dissolving what was left in alcohol, adding lead acetate to the solution, filtering, precipitating the lead with hydrogen sulphide, and evaporating. The *euonymin* obtained was uncrystallizable, intensely bitter, soluble in water and alcohol, and neutral in its reactions. It was abundantly precipitated from its solution by lead subacetate and phosphomolybdic acid. (*A. J. P.*, 1862, p. 387.) W. P. Clothier found the bark to yield no volatile oil on distillation. According to the same writer, if a concentrated tincture be poured into water, a dark yellow substance will be thrown down, containing resin and fixed oil, which is the *euonymin* of the eclectics,¹ very improperly so named, as, though it contains a portion of the active principle, it is a very complex substance. Clothier found the bark to purge actively without griping. (*Ibid.*, 1861, p. 491.) Frank V. Cassaday (*A. J. P.*, 1889, p. 284) found 1.30 per cent. of volatile oil and resin, 1.48 per cent. of *euonic acid* and resin, 2.10 per cent. of *euonymin* and resin, together with the usual plant constituents. Kubel has discovered in the fresh inner bark of *E. europæus* a saccharine, crystallizable substance, closely resembling mannite, but differing in its crystalline form and in its melting point. He calls it *euonymite*. (*J. P. C.*, Dec. 1862, 523.)

Uses.—This bark was first introduced into notice, as a remedy for *dropsy*, under the name of Wahoo,² by George W. Carpenter. In some cases it acts as a mild cathartic, but at other times it fails to produce purgation. We have also seen distinct evidences of an irritant influence upon the gastro-intestinal mucous membrane. Cholagogue properties have been ascribed to it, and probably with correctness, as in the experiments of Rutherford it was found to act most powerfully in causing hepatic secretion in dogs, and in some clinical studies we have made it seemed to have a similar action on man. The fluidextract of it is an efficient preparation, and may be given in doses, as a purgative, of one to two fluidrachms (3.75 to 7.5 Cc.); as a laxative, of half a fluidrachm to one fluid-

drachm (1.8 to 3.75 Cc.). (See also *Extractum Euonymi*, *U. S.*, and *Extractum Euonymi Siccum*, *Br.*)

Dose, of euonymus, five to fifteen grains (0.32 to 1.0 Gm.).

EUPATORIUM. U. S.

EUPATORIUM [Boneset, Thoroughwort]

(eū-pā-tō'ri-ūm)

"The dried leaves and flowering tops of *Eupatorium perfoliatum* Linné (Fam. *Compositæ*)." *U. S.*

Herba Eupatori Perfoliati; Indian Sage, Thorough-stem, Cross-wort, Thorough-wax, Sweating Plant; Herbe d'Eupatoire perfoliée, Herbe à fièvre, Herbe parfaite, *Fr.*; Durchwachsener Wasserhanf or Wasserdost, *G.*

Of this numerous genus, comprising not less than thirty species within the limits of the United States, most of which probably possess analogous medicinal properties, *E. perfoliatum* alone now holds a place in our national Pharmacopœia, *E. purpureum* and *E. teucrifolium* having been discarded at the revision of 1840. They merit, however, a brief notice, if only for their former official rank.

Eupatorium purpureum, or *gravel root*, is a perennial herbaceous plant, with a purple stem, five or six feet in height, and furnished with ovate-lanceolate, serrate, rugosely veined, slightly scabrous, petiolate leaves, placed four or five together in the form of whorls. The flowers are purple, and consist of numerous florets contained in an eight-leaved involucre. It grows in swamps and other low grounds, from Canada to Florida, and flowers in August and September. The root has, according to Bigelow, a bitter aromatic and astringent taste, and is said to be diuretic. Its vulgar name boneset indicates the popular estimation of its virtues. J. U. Lloyd found in it an apparently new, yellow, neutral, crystalline principle, *euparin*. (*A. J. P.*, 1890.) This euparin, with a number of derivatives, has been prepared by C. C. Mauger (*A. J. P.*, 1894, 120) and analyzed. The formula $C_{12}H_{11}O_3$ is assigned to it.

Eupatorium verbenacfolium, Michx., *Flor. Am.* ii. 98.—*E. teucrifolium*, Willd., *Sp. Plant.* iii. 1753.—*E. pilosum*, Walt., *Flor. Car.*, 199, commonly called *wild horehound*, is also an indigenous perennial, with an herbaceous stem, which is about two feet high, and supports sessile, distinct, ovate, acute, scabrous leaves, of which the lower are coarsely serrate at the base, the uppermost entire. The flower-heads are small, white, composed of five florets within each involucre, and arranged in the form of a corymb. The plant grows in low wet places from New England to Georgia, and abounds in the Southern States. It is in flower from August to November. The whole herb is used. In sensible

¹ For an examination of commercial *euonymin* (the eclectic resinoid) by Paul Thibault, see *N. R.*, 1883, 294.

² The name of Wahoo or Waahoo (pronounced *Wawhoo*) was given to it by the Indians. The same name has also been applied to *Ulmus alata*, of the Southern States, and has thus led to mistakes.

properties it corresponds with *E. perfoliatum*, though less bitter and disagreeable, and has been used for similar purposes and in like manner. *E. incarnatum* and *E. aromaticum* are said to contain an aromatic principle similar to if not identical with coumarin, obtained by Guibourt from *Dipteryx odorata*, or Tonka bean. (See *P. J.*, Oct. 1874, 303.) The roots of *E. aromaticum* are said to be sold in the Western United States under the name of *white snake-root*. *E. cannabinum*, of Europe, the root of which was formerly used as a purgative, and *E. triplinerve*, Vahl (*E. Aya-pana*, Vent.), of Brazil, the leaves of which at one time enjoyed a very high reputation, have fallen into neglect. The *Aya-pana* is an aromatic bitter, like *E. perfoliatum*, but weaker, and is said to be still occasionally met with in European commerce. (*A. J. P.*, 1887, 154; *Ph. Era*, 1898, 293.) *E. villosum* is used in Jamaica, under the name of *bitter-bush*, in the preparation of beer, as a tonic, and as a stimulant in low zymotic diseases. (*P. J.*, Oct. 1866; *A. J. P.*, 1887, 155.) *E. collinum* is included in the Mexican Pharmacopœia.

Eupatorium perfoliatum, Willd., *Sp. Plant.* iii. 1761; Bigelow, *Am. Med. Bot.*, i. 33; Barton, *Med. Bot.*, ii. 125.—*E. conatum*, Michx.—*E. salviaefolium*, Linné.—*Thoroughwort*, or *boneset*, is an indigenous perennial plant, with numerous herbaceous stems, which are erect, round, hairy, from two to five feet high, simple below, and trichotomously branched near the summit. "Usually occurring in fragments; leaves opposite, the pair united at the base, from 8 to 20 Cm. long and 1.5 to 5 Cm. broad, tapering regularly from near the base to an acute apex, crenate-serrate, rugosely veined, rough and bright green above, yellowish-gray-green, tomentose and resinous-dotted beneath; flower-heads small, numerous, corymbed, with a campanulate involucre of lance-linear imbricated scales and with from 10 to 15 tubular yellowish-white florets, having a bristly pappus in a single row; odor faintly aromatic; taste strongly bitter." *U. S.* The leaves serve to distinguish the species at the first glance. They may be considered either as perforated by the stem, *perfoliate*, or as consisting each of two leaves, joined at the base, *connate*. In the latter point of view, they are opposite and in pairs, which decussate each other at regular distances upon the stem; in other words, the direction of each pair is at right angles with that of the pair immediately above or beneath it. They are narrow in proportion to their length, broadest at the base where they coalesce, gradually tapering to a point, serrate, much wrinkled, paler on the under than on the upper surface, and beset with whitish hairs, which give them a grayish-green color. The uppermost pairs are sessile, not joined at the base. The flowers are white, numerous, supported on hairy peduncles, in dense corymbs, forming a flattened summit. The involucre, which is cylindrical and composed of imbricated, lanceolate, hairy scales, encloses

from twelve to fifteen tubular florets, having their border divided into five spreading segments. The anthers are five, black, and united into a tube, through which the bifid filiform style projects.

This species of *Eupatorium* inhabits meadows, the banks of streams, and other moist places, growing generally in bunches, and abounding in almost all parts of the United States. It flowers from the middle of summer to the end of October. All parts of it are active, but the herb only is official. It has a faint odor, and a strongly bitter, somewhat peculiar taste. The virtues of the plant are readily imparted to water and alcohol. W. Peterson found it to contain a peculiar bitter principle, chlorophyll, resin, a crystalline matter of undetermined character, gum, tannin, yellow coloring matter, extractive, lignin, and salts. (*A. J. P.*, xxiii. 210.) Bickley found also albumen, gallic acid, and signs of volatile oil. (*Ibid.*, xxvi. 495.) Peter Collier, chemist of the Department of Agriculture, submitted it to analysis, finding 18.84 per cent. of bitter extractive, which he considers the constituent of medicinal importance, 2.87 per cent. of an indifferent crystalline substance, obtained from the alcoholic extract, and traces only of a volatile oil. (*Ibid.*, 1879, p. 342.) George Latin (*A. J. P.*, Aug. 1880) found a glucoside, *eupatorin*, and a crystallizable body of the nature of a wax. O. F. Dana, Jr., obtained 3.80 per cent. of extract with petroleum benzin; 4.60 per cent. with ether; 33.80 per cent. with alcohol; 24.80 per cent. with water; 5.80 per cent. with alkali. (*A. J. P.*, 1887, p. 229.) A number of analyses of *E. perfoliatum* have been published within the last decade by Dana, Latin, Franz, and Kaercher, but neither the crystalline principle nor any of its salts had been analyzed until Shamel (*Am. Chem. J.*, 1892, p. 224) published an analysis of the nitrate. He gives for it the formula $C_{20}H_{25}O_{16}HNO_3$.

Uses.—*Eupatorium* is tonic, diaphoretic, and in large doses emetic and aperient, and was at one time employed as an antiperiodic. Given in warm infusion, so as to produce vomiting or copious perspiration, at the commencement of *influenza*, of *muscular rheumatism* or a *general cold*, it will sometimes abort the attack. As a tonic it is given with advantage in *dyspepsia*, general debility, and other cases in which the simple bitters are employed. H. S. Wilkins has found the infusion useful in the expulsion of *tapeworm*. (*A. J. P.*, 1874, p. 295.)

With a view to its tonic effects, it is best administered in substance, or cold infusion. The aqueous extract has been used with advantage. When the diaphoretic operation is required in addition to the tonic, the infusion should be administered warm, and the patient remain covered in bed. As an emetic and cathartic, a strong decoction, prepared by boiling an ounce with three half-pints of water to a pint, may be given in doses of from four fluidounces to a half-pint (120 to 240 Cc.), or more. (See *Fluidextractum Eupatorii*.)

Dose, twenty to thirty grains (1.3 to 2.0 Gm.).

Off. Prep.—Fluidextractum Eupatorii, U. S.

EXTRACTA.

EXTRACTS

(ex-trăc'tă)

Extracts, *Fr.*; Extrakte, *G.*; Estratti, *It.*; Extractos, *Sp.*

Extracts, as the term is employed in the Pharmacopœias, are solid preparations, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing a dried drug to the action of a solvent, or by expressing the juice from a fresh plant. A distinction was formerly made between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, the former being called *Extracta*, the latter *Succi Spissati*, but the distinction has been generally abandoned. There is no such essential difference between these two sets of preparations as to require that they should be separately classed, and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant with as little of the inert matter as possible, though sometimes it may be desirable to separate two active ingredients from each other, when their effects upon the system are materially different; this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, coloring matter, salts, and the peculiar principles of plants, to which, when an alcoholic solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil, gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in this commentary. There is one, however, which, from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive*, or, as it is sometimes called, *extractive matter*.

It has long been observed that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first a greenish, then a yellowish brown, and ultimately a deep brown color, and becoming itself insoluble. This sub-

stance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive name of *extractive*, derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted, by some chemists, who consider the phenomena supposed to result from its presence as depending upon the mutual reaction of other principles, and in relation to Peruvian bark it appears to have been proved that the insoluble matter which forms during its decoction in water is a compound of starch and tannin. A similar compound must also be formed in other cases when these two principles coexist; but they are not always present in the same vegetable, nor can all the changes which have been attributed to extractive be accounted for by their union, even when they are present; so that, until further light is shed on the subject, it is best to admit the existence of a distinct class of substances, which, though not the same in all plants, possess sufficient identity of character to be entitled, like sugars, resins, etc., to a generic name. The most important property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. If chlorine be passed through an infusion or decoction, a similar precipitate is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has, therefore, been called, in its altered condition, oxidized extractive; but De Saussure ascertained that, though oxygen is absorbed during the process, an equal measure of carbon dioxide is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is, therefore, obviously incorrect, and Berzelius proposed to substitute for it that of *apotheme*, synonymous with deposit; apotheme seems to be similar in properties to *humin*. According to Berzelius, apotheme is not completely insoluble in water, but imparts a slight color to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it, thus acquiring properties somewhat different according to the source from which it is obtained. In this way also, even when the extractive of a plant is itself medicinally inert, its conversion into apotheme may be injurious by causing a precipitation of a portion of the active prin-

ciple, and in practical pharmaceutical operations this change should always, if possible, be avoided. With these preliminary views, we shall proceed to the consideration of the practical rules necessary to be observed in the preparation of extracts. We shall treat of the subject under the several heads of—1, the extraction of the soluble principles from the plant; 2, the method of conducting the evaporation; 3, the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract: 1, by expression alone; 2, by the agency of a solvent, with or without expression.

1. By Expression.—This method is applicable to recent vegetables. All plants cannot be usefully treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable portion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects for this treatment. The plants should be operated upon, if possible, immediately after collection. Battley of London, recommended that, if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvas bag, and the liquid parts expressed. Brande states that light pressure only should be employed, as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. (*Practice of Pharmacy.*) The juice thus obtained is opaque, and usually green, in consequence of the presence of green wax or chlorophyll, and of a portion of the undissolved vegetable fibre in minute division. By heating the juice to about 71.1° C. (160° F.) the albumen contained in it coagulates, and, involving the chlorophyll and vegetable fibre, forms a greenish precipitate. If the liquid be now filtered, it becomes limpid and nearly colorless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle, in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of syrup. Ether added to the expressed juices of plants enables them to be kept long without injurious change. Lepage of Gisors, France, has kept the juice of belladonna

in this way more than ten years, and found it, at the end of that time, to yield an extract identical in physical, chemical, and physiological properties with that obtained from the fresh juice. If this fact is found to be of general applicability, it will be of considerable importance, as enabling the pharmacist to supply himself at pleasure with extracts to be relied on, without reference to the season.

2. By Solution.—The active principles of dried vegetables can be extracted only by means of a liquid solvent. The menstruum usually employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action, if necessary, by a higher degree of heat than the latter. Pump water is often unfit for the purpose, in consequence of the quantity of its saline matter, which in some instances may exert an unfavorable influence on the active principle, and must always be left in the extract. Rain, river, or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils or the active principles of sarsaparilla; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The aqueous solution requires to be quickly evaporated, as this fluid rather promotes than counteracts chemical changes, while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable, and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively than of both united. Extracts obtained by the agency of water are called *aqueous extracts*; those by means of alcohol, undiluted or diluted, *alcoholic* or *spirituous extracts*. Sometimes the term *hydro-alcoholic* is applied to extracts obtained by the joint agency of alcohol and water.

The method of preparing the solution is not a matter of indifference. The drug should be thoroughly bruised, or reduced to a coarse powder, so as to allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved or inactive portion. When water is alone employed, it has been customary to boil

the medicine for a considerable time, and, if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions until the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the decomposition of many vegetable principles, or at least so modifies them as to render them inert, and the extracts, prepared by decoction are usually less efficient than those made with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat employed. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot infusion, in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is often preferable to the other modes, as starch, which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By *digestion*, though the solvent power of water is moderately increased, the advantage is often more than counterbalanced by the increased disposition to spontaneous decomposition. *Hot infusion*, therefore, is to be preferred where the vegetable does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without adding to its virtues. A convenient mode of performing this process is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel having a notched cork in its mouth, then to pour on the boiling water, and, having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated until the water comes away without any obvious impregnation.

It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both when decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it.

Sometimes the filtering of a turbid infusion or decoction, before evaporation, causes the resulting extract to keep better, by removing substances which, besides undergoing decomposition, may act as a ferment, and occasion the decomposition of the active matter of the extract.

When alcohol is employed as a menstruum, the vegetable should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration, as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels. When alcohol and water are both used, it is best, as a rule, to exhaust the substance with each separately, as the two menstrua require different modes of treatment. In whichever of these modes the extraction is effected, it requires the assistance of occasional agitation, and when the vegetable matter is very porous, and absorbs a large quantity of the solvent, expression must be resorted to.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and still stronger with alcohol to which strong acetic acid has been added. (*J. P. C.*, 3e sér., i. 239.) This acid is used in the preparation of the extracts of colchicum and nuxvomica. Experiments have shown that strong acetic acid (60 per cent.) is a powerful solvent for the active properties of various drugs, particularly those which contain volatile oils, and in many cases a 10 per cent. acetic acid is an excellent menstruum for making extracts; for these the name *acettract* has been proposed. (*Proc. A. Ph. A.*, 1897, 416.) E. R. Squibb has used acetic acid largely for extracts. (*West. Drug.*, 1897, 123.)

Ether also is now used to a considerable extent in the preparation of certain extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the preparation of extracts from those substances the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation, and the ether is then allowed to escape by spontaneous evaporation, or distilled off at a very moderate heat. The oleo-resinous extracts thus obtained are usually of a thick fluid or semi-fluid consistence. Several of them now rank among the official preparations, in the U. S. P., under the title of *Oleo-resinae*.

The process of *percolation* has in this country been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages: 1, that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion; 2, that it effects the extraction much more quickly than can be

done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and, 3, that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing the injurious effects of the subsequent evaporation. While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed, for, though an inexperienced or careless operator may incur loss by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskillfully prepared upon this plan. In the U. S. P., all the extracts to which the process is applicable are prepared by percolation, and with merely sufficient previous maceration or digestion to thoroughly soften the tissues. In the Br. Ph., the process is applied, as it were, hesitatingly to some of the extracts, and withheld in others to which it seems equally appropriate. In the process of percolation the drug must first be reduced to the proper degree of fineness. The U. S. P. (8th Rev.) gives the following directions.

"Fineness of Powder."—The fineness of powder is expressed, in the Pharmacopœia, either by descriptive words (generally so in the case of brittle or easily pulverizable substances), or in terms expressing the number of meshes to a linear inch of the sieve through which the powder will pass. The corresponding values, in terms of metric measures of length, are added below in parentheses, but it has not been deemed advisable, in this revision, to substitute them in the text of the Pharmacopœia for those at present in use. The diameter of the wire (gauge number) used in making sieve cloth has an important influence upon the size of the mesh, and it is necessary to specify in each case the thickness of the wire.

These different forms of expression correspond to each other as follows:

In certain cases, powders of a different degree of fineness (*e.g.*, No. 30, No. 12) are directed to be taken." U. S.

"Percolation," as directed in the U. S. Pharmacopœia, consists in subjecting a substance or a mixture of substances, in powder, contained in a vessel called a percolator, to the solvent action of successive portions of a certain menstruum in such a manner that the liquid, as it traverses the powder in its descent to the receiver, shall be charged with the soluble portion of it, and pass from the percolator free from insoluble matter.

When the process is successfully conducted, the first portion of the liquid, or percolate, passing through the percolator, will be nearly saturated with the soluble constituents of the substance treated; and if the quantity of menstruum be sufficient for its exhaustion, the last portion of the percolate will be nearly free from color, odor, and taste, other than those of the menstruum itself.

Percolators.—The percolator most suitable for the quantities contemplated by this Pharmacopœia should be nearly cylindrical, or slightly conical, with a funnel-shaped termination at the smaller end. The neck of this funnel-end should be rather short, and should gradually and regularly become narrower toward the orifice, so that a perforated cork, bearing a short glass tube, may be tightly wedged into it from within until the end of the cork is flush with the outer edge of the orifice. The glass tube, which must not project above the inner surface of the cork, should extend from 3 to 4 Cm. beyond the outer surface of the cork, and should be provided with a closely fitting rubber tube, at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band holding the tube in position.

A <i>very fine</i> powder	{ should pass through a sieve having 80 or more meshes to the linear inch (30 meshes to the centimeter) which should be made from gauge No. 38 wire—	= No. 80 powder.
A <i>fine</i> powder	{ should pass through a sieve having 60 meshes to the linear inch (24 meshes to the centimeter) which should be made from gauge No. 36 wire—	= No. 60 powder.
A <i>moderately fine</i> powder	{ should pass through a sieve having 50 meshes to the linear inch (20 meshes to the centimeter) which should be made from gauge No. 35 wire—	= No. 50 powder.
A <i>moderately coarse</i> powder	{ should pass through a sieve having 40 meshes to the linear inch (16 meshes to the centimeter) which should be made from gauge No. 33 wire—	= No. 40 powder.
A <i>coarse</i> powder	{ should pass through a sieve having 20 meshes to the linear inch (8 meshes to the centimeter) which should be made from gauge No. 28 wire—	= No. 20 powder.

The shape of a percolator should be adapted to the nature of the drug to be operated upon. For drugs which are apt to swell, particularly when a feebly alcoholic or an aqueous menstruum is employed, a conical percolator is preferable. A cylindrical or only slightly tapering percolator may be used for drugs which are not liable to swell, and when the menstruum is strongly alcoholic, or when ether or some other volatile liquid is used for extraction. The size of the percolator selected should be in proportion to the quantity of drug extracted. When properly packed in the percolator, the drug should not occupy more than two-thirds of its height. The percolator is best constructed of glass, but, unless otherwise directed, may be made of any suitable material not affected by the drug or menstruum.

The percolator is prepared for percolation by gently pressing a small tuft of cotton into the neck above the cork, and this may then be moistened by pouring a few drops of the menstruum upon the cotton, to facilitate the passage of the first portion of percolate, which is often very dense.

The Process.—The powdered substance to be percolated (which must be uniformly of the fineness directed in the formula, and should be perfectly air-dry before it is weighed) is put into a basin, the specified quantity of menstruum is poured on, and the powder thoroughly stirred with a spatula, or other suitable instrument, until it appears uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders, and those which are finer, requiring a No. 20 sieve, while No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from fifteen minutes to several hours, unless otherwise directed; after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum, strongly alcoholic menstrea, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disk of filtering paper, or other suitable material, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions be accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent

evaporation. The apparatus is then allowed at rest for the period of time specified in the formula.

To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for the quantity of liquid to be percolated, if the percolate is to be measured, or of a tared bottle, if the percolate is to be weighed; and by raising or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable. A layer of menstruum must constantly be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator so that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator.

When the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on, until all has passed from the surface, when immediately a sufficient quantity of the original menstruum should be poured on to displace the absorbed liquid, until the prescribed quantity has been obtained.

Repercolation.—Authority is given (by the U. S. P. 8th Rev.) to employ, where it may be applicable, the process of repercolation, without change of the initial menstruum.

Rate of Flow.—It is obvious that the success of the process of percolation largely depends upon the regulation of the flow of the percolate; if this should be too rapid, incomplete exhaustion will result, but if too slow, valuable time may be wasted. The rate of flow for extracts and fluidextracts for 1000 Gm. of powder should range from two to five drops a minute; for official quantities of tinctures and preparations of about the same strength from eight to fifteen drops a minute, and the word "slowly" throughout the text is understood to mean a rate of flow corresponding to this; it is evident that the proper rate of flow should vary with the quantity and character of the drug used and the density of the menstruum.

Maceration.—Percolation is not suitable for exhausting some drugs and the process of maceration is employed for some of the tinctures (Aloes, Asafetida, Sweet Orange Peel, Tolu, etc.). Specific directions will be found under each process, and maceration should be conducted at a moderately warm temperature, about 15° to 20° C. (59° to 68° F.), and in a shady place." U. S.

For an account of E. R. Squibb's process of repercolation, see *Fluidextracta*.

Some prefer the mode of expression to that of percolation. This also is applicable both to aqueous and to alcoholic menstrua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances, and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of a common screw press, or other convenient apparatus. Another portion of the menstruum may then be added, and pressure again applied, and, if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantages over that of the percolation, that it yields solutions of more uniform concentration, that it does not require the materials to be so carefully powdered, or otherwise so skilfully managed, in order to insure favorable results, and, finally, that it occupies less time.

2. Mode of Conducting the Evaporation.

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapor. The operator should, therefore, observe two rules: 1, to conduct the evaporation at as low a temperature as is consistent with other objects; 2, to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. The injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case, and therefore a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe that decoctions generally let fall, upon cooling, a portion of insoluble matter, and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble substance formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a rule, is to allow it to remain.

The method of evaporation formerly resorted to in the case of aqueous solutions is rapid

boiling over a fire. The more quickly the process is conducted, the better, provided the liquid is to be brought to the boiling point, for the temperature cannot exceed this, and the length of exposure is diminished. But, where this method is employed, it should never be continued until the completion of the evaporation, for when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire before it has attained the consistence of thick syrup, and completing the evaporation, either by means of a water bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions and evaporate each separately, for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. (Mohr.) But the mode of evaporation by boiling is always objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by the method of decoction.

Evaporation by means of the water bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but, as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and, the temperature being nearly the same, when the water bath is kept boiling, there is greater risk of injurious action from the air. The liquid should be stirred during the process. The use of the steam bath has become very general in this country, as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, may be less than 100° C. (212° F.). The apparatus consists of an ordinary boiler, containing water, the vapor of which is conducted through a pipe into the evaporating vessels, communicating with each other by means of iron steam pipes. These vessels have the form of an ordinary copper basin, to the inside of which is riveted a shallow tinned copper evaporating basin, intended to contain the liquid to be evaporated. The vapor from the boiler circulates between these vessels, and the water into which it condenses is allowed to escape through a steam valve attached to the bottom of each vessel. The liquid to be evaporated is first distributed in two or three basins, but when considerably concentrated, is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid can be easily regulated by the steam valves.

As the heat capable of being applied by boiling water to the evaporating liquid does not exceed 93.3° C. (200° F.), while that by steam can, by a moderate pressure, be increased to the boiling point or beyond it, the evapora-

tion by the latter agency may be much more rapid than by the former, when the pressure is from ten to twenty pounds to the square inch; so that there is a temptation to raise the heat to a degree seriously injurious to the product. Evaporation, therefore, by steam heat always requires caution and a stirring device should be used. The water bath is much less liable to be abused. In this respect the latter method has the advantage.

A good plan of evaporation, though slow, is to place the liquid in a broad, shallow vessel, exposed in a stove or drying room to a temperature of about 100° F., or a little higher, taking care that the air have free access in order to facilitate the evaporation. This mode is particularly applicable to those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while extracts prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smith's bellows, over the surface of the liquid, and in reference to substances which are injured by heat and not by atmospheric air the plan will be found useful.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for *evaporation in vacuo*, now largely used by manufacturing pharmacists, is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapor more rapidly, and at a comparatively low temperature.

A convenient plan of excluding the air, though it does not at the same time meet the object of reducing the degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo*. Care, however, must be taken that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water bath.

In the concentration of alcoholic solutions, distillation should always be performed, as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water bath should be employed, to obviate any possible risk of injury from the fire. When the decoction or infusion and the tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together while they are of such a consistence as to incorporate

without difficulty. The object of this separate evaporation is that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat therefore, should be applied to the bottom and not to the sides of the vessel.

Inasmuch as the yield of extracts is largely dependent on the character of the menstruum used in the percolation, it follows that there must necessarily be a great variation in the strength of commercial extracts. C. H. LaWall has prepared a valuable table giving the yield of extract by various drugs. (*Proc. A. Ph. A.*, 1897, 414.) For methods of assay, see various official processes.

3. Condition and Preservation of Extracts.

Extracts may be prepared of three different degrees of consistence: soft so that they may be readily made into pills, hard in order that they may be pulverized, and in a fine, dry powder. The soft extracts always contain a notable percentage of water. In astringent extracts, the evaporation should be carried to dryness. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophyll, harden by time, in consequence of the escape of their moisture, and it not unfrequently happens that small crystals of saline matter are formed in their substance; sodium chloride in small cubes is sometimes found in certain old extracts, having slowly crystallized as they hardened. John Attfield of London, has made a chemical examination of the crystals found in numerous extracts, and ascertained that in a large number they consisted of potassium chloride, and in a comparatively few of potassium nitrate. Potassium chloride was detected in the extracts of belladonna, hemlock, sarsaparilla (compound), colchicum seed, stramonium seed, and aconite; potassium nitrate in the extracts of belladonna, hyoseyamus, and lettuce; and sodium sulphate in extract of stramonium seed. (*P. J.*, March, 1862, p. 448.) The air, moreover, exercises an unfavorable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt or any other very soluble salt of difficult decomposition, the greater part of it will be precipitated, in consequence of

the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water.

Abstracts, which were official in the U. S. P. 1880, were not re-introduced in the U. S. P. (8th Rev.), as they did not come into general use; this is unfortunate, as they had many advantages, and are used in certain sections of the country. A description and a typical formula, with comments, are appended.¹ Abstracts of the following eleven drugs were official in 1880: aconite, belladonna root, conium, digitalis, hyoseyamus, ignatia, jalap, nux vomica, podophyllum, senega, and valerian. C. S. N. Hallberg favors the use of a menstruum of three measures of alcohol with one of chloroform for abstracts, and prefers the term "*quatract*" to "*abstract*." (*Proc. A. Ph. A.*, 1894, 245.)

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from

the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather or a piece of bladder. The application of alcohol to the surface has a tendency to prevent mouldiness. Should the extract become too moist, it may be dried by means of a water bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner and incorporating with it a little distilled water. Martin (1880) proposes to preserve extracts in a soft condition by surrounding the vessel containing the extract by another of larger diameter, which is furnished with a tight cover, the space between the two vessels being filled with crystallized sodium sulphate, which gradually parts with its water of crystallization and prevents the extract from becoming hard and dry.

When extracts which are too soft are subjected to a moderate temperature, fermentation may set in; E. Coccardas describes the various forms of "*Penicillium-ferment*" which are found in such extracts, and concludes that the ferment causes them to undergo changes similar to those effected by heat,—viz., the absorption of oxygen and the disengagement of carbon dioxide. (*P. J.*, 1886, p. 590.)

Powdered Extracts.—These extracts are largely superseding soft extracts for reasons given in preceding paragraphs; the difficulty of making them arises from the injurious influence of heat upon concentrated percolates of organic substances, but by the use of vacuum apparatus, suitable absorptive diluents and care, they should be made successfully.

General Formula for Official Powdered Extracts.—Evaporate the Fluidextract of the drug at a temperature not exceeding 70° C. (158° F.) with constant stirring, to complete dryness. Reduce the product to a fine powder and add enough powdered glycyrrhiza to make the finished extract weigh — Gm. Mix thoroughly. Permission is given by the U. S. P. (8th Rev.) to use instead of powdered glycyrrhiza the dried and powdered marc from the same drug. Powdered extracts should be kept in tightly closed vials and in a cool place.

Some extracts when powdered have a tendency to cohere. According to Geiseler, this may be obviated by the addition of sugar of milk or powdered licorice root, two or three parts of the former and one part of the latter to one of the extract being sufficient for the purpose. (*Ph. Cb.*, 1850, p. 238.) Mohr recommends the following plan of drying and preserving extracts. Take equal parts of powdered licorice-root and of the extract, rub them well together in a mortar, put the resulting paste into an earthen vessel with a flat bottom, place this in another of iron, a little deeper, containing calcium chloride thoroughly dried by heat insufficient to melt it; then enclose

¹ *ABSTRACTA. Abstracts*.—Abstracts are solid powdered preparations containing the soluble constituents of the drugs from which they are made, and to which they bear a definite and uniform relation. These preparations were first introduced into the U. S. Pharmacopœia of 1880, and have many advantages over ordinary extracts. They are prepared by evaporating an alcoholic tincture of a drug spontaneously and at a low temperature, mixing it with a sufficient quantity of dried sugar of milk to make the final product when dry weigh one-half the weight of the drug, and then powdering it. The following general formula exhibits the typical former official process.

General Formula.—Drug, in No. 60 powder, two hundred parts [or four ounces av.]; Sugar of Milk, recently dried and in fine powder, Alcohol, each, a sufficient quantity, to make one hundred parts [or two ounces av.]. Moisten the drug with eighty parts [or one and three-quarter fluidounces] of Alcohol, and pack firmly in a cylindrical glass percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the drug is exhausted. Reserve the first one hundred and seventy parts [or three and one-half fluidounces] of the percolate, evaporate the remainder to thirty parts [or half a fluidounce] at a temperature not exceeding 50° C. (122° F.), and mix with the reserved portion. Place the mixture in an evaporating dish, and, having added fifty parts [or one ounce av.] of Sugar of Milk, cover it with a piece of thin muslin gauze, and set aside in a warm place, where the temperature will not rise above 50° C. (122° F.), until the mixture is dry. Lastly, having added enough Sugar of Milk to make the mixture weigh one hundred parts [or two ounces av.], reduce it to a fine, uniform powder. Preserve the powder in a well-stopped bottle.

The advantages possessed by abstracts may be briefly stated as follows:

1. Each abstract represents twice the strength of the drug or fluidextract from which it is prepared.

2. They are dry powders, if properly made, and thus are permanent and portable; not subject to precipitation as fluidextracts are; not liable to become hard, tough, and variable in strength, as is the case with extracts.

3. Injurious exposure to heat is entirely avoided, and the official process requires no apparatus but such as either is at hand in the pharmacy or can be easily obtained by a pharmacist operating upon the small scale.

4. The final thorough trituration of the dry powder reduces the soluble and active constituents of the drug to a pulverulent condition, the diluent is soluble, and the fine state of division of abstracts is the most favorable condition that a powder can possess to secure efficient medication. (*Remington's Practice of Pharmacy*, 4th ed., p. 456.)

the whole with a cover fitted to the iron vessel, and allow them to stand for a day or more. When the mixture is quite dry, powder it, and add so much of the powdered root as to make the weight double that of the original extract. This process was substantially adopted in the German Pharmacopœia (1882). The old process of using dextrin as a diluent was found very objectionable, principally on account of the tendency of the extracts to reabsorb moisture. Four parts of extract are now mixed with three parts of finely powdered licorice-root, and dried in a porcelain dish at 40° to 50° C. (104° to 122° F.) until the mixture ceases to lose weight. The mass is then rubbed to powder, and sufficient powdered licorice-root added to make the whole weigh eight parts, or double the weight of extract used. In our opinion, this method is not so good as that formerly adopted for abstracts. The German powdered extracts are always half the strength of the extracts, no relation whatever with the drug is established, and the variations in the yield of extract from different drugs have been repeatedly shown to be great. Kirchmann proposes exsiccated sodium sulphate as a diluent instead of dextrin, licorice-root, etc. (*Ph. Ztg.*, 1881, 116.) A. B. Lyons of Detroit (1898), has introduced *scale extracts*. These do not, as a class, bear a definite relation to the drug; they are assayed, however, and acacia is used as a means of preserving their dry condition; they are easily pulverized, and are very convenient for dispensing.

The plan of incorporating a little glycerin with extracts has been recommended for such extracts as require it, 10 per cent. of glycerin being added to the liquid extract before evaporating to a pilular consistence. By its unchangeable liquid character, glycerin keeps the extract soft, so that it can be readily made into pills, and it also exercises a favorable influence through its chemical properties. The U. S. P. (8th Rev.) directs the use of glycerin for this purpose as follows: "When it is desired to preserve a solid extract (for instance, of Gentian, Taraxacum, etc.) in a plastic condition, suitable for making pills, or for other purposes, it is recommended that there be incorporated with it, after it has been evaporated to the proper consistence, and while it is still warm, 10 percent. of its weight of glycerin." U. S. It is preferable to add a definite weight of the glycerin to the percolate. If it were added to the menstruum, owing to the variation in the yield of extracts from plants, some would be too soft, and at another time, in the case of a large yield of extract, the quantity of glycerin would be insignificant.

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; a good rule is to prepare them once a year; but the demand for extracts from fresh drugs has declined rapidly of late, as it has been found that properly dried drugs yield extracts of uniform strength.

Nine extracts were dismissed at the last revision of the U. S. Pharmacopœia, these were as follows:¹ aconite, arnica root, cinchona,

¹ *Extractum Aconiti*, U. S. 1890. *Extract of Aconite*, "Aconite, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until three thousand cubic centimeters [or 100 fluidounces] of tincture are obtained, or the Aconite is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate, evaporate the remainder in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters [or 3 fluidounces, 183 minims], add the reserved portion, and evaporate, at or below the above-mentioned temperature, until an extract of a pilular consistence remains." U. S. 1890.

This extract has been very properly abandoned by the U. S. P. (8th Rev.), as it has been shown that heat injuriously affects liquid preparations of aconite. For comments see 18th ed. U. S. D., p. 538.

Dose, one-sixth of a grain to one-fourth of a grain (0.01 to 0.016 Gm.).

Extractum Arnica Radicis, U. S. 1890. The omission of *Emplastrum Arnica* from the Eighth Revision of the U. S. P. very properly led to the dismissal also of the *Extract of Arnica Root*, since although the dose was given in the books as from three to five grains (0.2 to 0.32 Gm.) the extract was probably never used internally. The following process is that of the U. S. P. of 1890.

"Arnica Root, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Arnica Root is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate; evaporate the remainder to one hundred cubic centimeters [or 3 fluidounces, 183 minims], at a temperature not exceeding 50° C. (122° F.), mix the residue with the reserved portion, and evaporate, at or below the above-mentioned temperature, to a pilular consistence." U. S. 1890.

Extractum Cinchona, U. S. 1890. *Extract of Cinchona*,—"Cinchona, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, three thousand cubic centimeters [or 101 fluidounces, 212 minims]; Water, one thousand cubic centimeters [or 33 fluidounces, 63 fluidrachms]; Diluted Alcohol, a sufficient quantity. Mix the Alcohol and Water, and having moistened the powder with three hundred and fifty cubic centimeters [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Diluted Alcohol, until four thousand cubic centimeters [or 135 fluidounces, 122 minims] of tincture are obtained, or the Cinchona is exhausted. Distill off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." U. S. 1890.

The above former official process is excellent, and if proper care be taken in executing the process, both in relation to the percolation and the avoidance of too high a temperature, the extract will fully represent the virtues of the bark.

Uses.—The extract of Peruvian bark is at present much less employed than before the discovery of quinine. It is still, however, occasionally prescribed as a tonic in combination with other medicines.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.), equivalent to about a drachm (3.9 Gm.) of the powdered bark.

conium, iris, jalap, juglans, podophyllum, and uva ursi. Five extracts were added as follows: malt, cascara sagrada, scopola, stramonium, and sumbul.

EXTRACTUM ALOES. U. S.

EXTRACT OF ALOES

(ex-trăc'tum ăl'ô-ēs)

Extrait d'Aloës, Fr.; Extractum Aloës, P. G.; Aloeextract, G.; Estratto di aloë acquoso, It.

* "Aloes, one hundred grammes [or 3 ounces av., 231 grains]; Boiling Water, one thousand

Extractum Conii, U. S. (1890). *Extract of Conium*. Extract of Hemlock; Extrait de Ciguë (Semenae), Fr. Cod.; Schierlingsextract, G.—"Conium, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Acetic Acid, twenty cubic centimeters [or 324 minims]; Diluted Alcohol, a sufficient quantity. Mix the Acetic Acid with nine hundred and eighty cubic centimeters [or 33 fluidounces, 66 minims] of Diluted Alcohol, and, having moistened the powder with three hundred cubic centimeters [or 10 fluidounces, 70 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until three thousand cubic centimeters [or 101 fluidounces, 212 minims] of tincture are obtained or until the Conium is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters [or 3 fluidounces, 183 minims], mix this with the reserved portion, and evaporate, at or below the above-mentioned temperature, to a pilular consistence." U. S. 1890.

Under the present name two extracts are found in commerce, one, that of the U. S. P. (1890), an alcoholic extract made from conium fruit, the other, the British (1885) extract, made from the fresh leaves and young branches of the plant. In the U. S. extract acetic acid is used to fix the alkaloid conine.

The most important point in making the Br. Ph. (1885) extract is to evaporate the juice without an undue degree of heat. At a temperature of 100° C. (212° F.), or upwards, its active principle undergoes rapid decomposition, being converted into resinous matter and ammonia. This is detected by the operator by the ammoniacal odor mixed with that which is peculiar to the plant. The juice always to a certain extent undergoes this decomposition when evaporated over a fire, and is not exempt from it even when the heat is regulated by a water bath. Hence the propriety of the directions in the Br. Ph. (1885). An excellent plan in the evaporation is to conduct it first in a vacuum, and afterwards in shallow vessels with a current of air at common temperatures. By the direction to heat the juice to the boiling point, or 93.3° C. (200° F.) (Br.), and then to filter, whereby the inert albumen is coagulated, and, with the equally inert chlorophyll and vegetable fibre, is separated from the liquid before evaporation, the extract is procured in a more concentrated state, and, besides, deprived of substances which might favor its decomposition. Long continued exposure to the air is productive of the same result as too much heat, so that old extracts are frequently destitute of activity. (J. P. C., xxii. 416.) No one of the extracts is more variable in its qualities than this. The season at which the herb is collected, the place and circumstances of its growth, the method of preparing the extract, are all points of importance, and are all too frequently neglected. The activity of any specimen of the extract may be in some measure judged of by rubbing it with potassium hydroxide, which, disengaging the conine and rendering it volatile, gives rise to the peculiar mouse-like odor of that principle. If no odor be evolved under these circumstances, the extract may be deemed inert.

The extract of conium prepared without separating the chlorophyll has a fresh olive or green color. It should have a strong narcotic, somewhat fetid odor, and a bitterish saline taste. According to Brande, from three to five pounds are obtained from one cwt. of the leaves. M. Recluz obtained rather more than an ounce from sixteen ounces.

Dose, of the U. S. P. 1890 extract, one-half to one grain (0.032 to 0.065 Gm.), of the British extract, two grains (0.13 Gm.), two, three, or four times a day, to be gradually increased *pro re nata*, in pill or solution.

Extractum Jalapæ, U. S. 1890. *Extract of Jalap*. "Jalap, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity. Moisten the powder with three hundred and fifty cubic centimeters [or 11 fluidounces, 400 minims] of Alcohol, and pack it firmly in a cylin-

dricul percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Jalap is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate. Distill off the Alcohol from the remainder by means of a water-bath, add the residue to the reserved portion, and evaporate to a pilular consistence." U. S. 1890.

Extractum Podophylli, U. S. 1890. *Extract of Podophyllum*.—"Podophyllum, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity. Mix eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of Alcohol with two hundred cubic centimeters [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Podophyllum is exhausted. Distill off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." U. S. 1890.

This is possessed of the purgative properties of the root, and may be given in the dose of from one to three grains (0.065 to 0.2 Gm.). From experiments made by John R. Lewis, it is probable that the alcoholic extract would be more powerful as a purgative than the official preparation; but it does not follow that it would be more serviceable. (See A. J. P., xix.)

Extractum Stramonii Seminis, U. S. 1890. *Extract of Stramonium Seed*.—"Stramonium Seed, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity. Moisten the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until three thousand cubic centimeters [or 101 fluidounces, 212 minims] of tincture are obtained, or the Stramonium Seed is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters [or 3 fluidounces, 183 minims]; mix this with the reserved portion, and by means of a water-bath, evaporate, at or below the before-mentioned temperature, to a pilular consistence." U. S. 1890.

Extractum Uvæ Ursi, U. S. 1890. *Extract of Uva Ursi*.—"Uva Ursi, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity. Mix two hundred cubic centimeters [or 6 fluidounces, 366 minims] of Alcohol with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Water, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Uva Ursi is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 min-

cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Aloes with the Boiling Water in a suitable vessel, stirring constantly until the particles of Aloes are thoroughly disintegrated, and allow the mixture to stand for twelve hours; then pour off the clear liquid, strain the residue, and evaporate the mixed liquids to dryness with the aid of a water-bath or steam-bath." *U. S.*

The object of this preparation is to afford an aloes purified from mechanical impurities. The process is based upon the British formulas for extracts of Barbados aloes and Socotrine aloes, but the former is alone official in the Br. Pharm. (See below.) With an official purified aloes, the necessity for this preparation is not obvious.¹ An extract made with cold distilled water was formerly official in the German Pharmacopœia, as was also the vitriolated extract, "*Extractum Aloes Acido Sulfurico Correctum*," made by suspending eight parts of extract of aloes in thirty-two parts of distilled water, adding drop by drop one part of pure sulphuric acid, and evaporating in a porcelain vessel to dryness.

Dose, two to ten grains (0.13 to 0.65 Gm.).

EXTRACTUM ALOES BARBADENSIS.

Br.

EXTRACT OF BARBADOS ALOES

(*ex-trăc'tum ăl'q-ēs bār-bā-dēn'sis*)

Extrait d'Aloès des Barbades, Fr.; Barbados-Aloe-extrakt, G.

"Barbados Aloes, in small fragments, 1 pound (Imperial) or 1000 grammes; Distilled Water, boiling, 1 gallon (Imp. meas.) or 10 litres. Add the Barbados Aloes to the Distilled Water and stir well until they are thoroughly mixed; set the mixture aside for twenty-four

hrs] of the percolate; evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Mix this with the reserved portion, and evaporate, at or below the before-mentioned temperature, on a water-bath, to a pilular consistence." *U. S.* 1890.

Dose, from five to ten grains (0.32 to 0.65 Gm.).
¹*Glycerite of Aloes. Glycerate of Aloes.*—Under the latter name, Chausit brought to the notice of the profession a preparation consisting of an alcoholic extract of aloes dissolved in glycerin. Haselden prepared this by the following method. Macerating half an ounce of aloes in four fluidounces of alcohol until dissolved, he filtered the tincture through bibulous paper, evaporated it to the consistence of molasses, and, while it was still warm, added enough glycerin to make four fluidounces. Finding that the aloes was wholly dissolved, with the exception of a little impurity, he concluded that the spirit might very well be dispensed with, and the aloes used directly in the process. Accordingly he proposes to substitute the following method. Mix well in a mortar half an ounce of Socotrine aloes, in fine powder, and four fluidounces of glycerin; transfer the mixture to a bottle, and agitate occasionally for several days; if the aloes be not now dissolved, heat for fifteen minutes by a water bath, and strain through linen to separate impurities. The resulting liquid is of a bright mahogany color, and of the consistence of glycerin. The preparation has been recommended as an external remedy in *Uchen agrius* and the excoriations of *eczema*, applied by means of a camel's hair brush. (*P. J.*, 1859, p. 322.) For the mode of preparing a *fluidextract of aloes* with the aid of glycerin, by Procter, see *Proc. A. Ph. A.*, 1863, p. 240.

hours; decant; strain; evaporate the strained liquid to dryness at a temperature not exceeding 140° F. (60° C.)." *Br.*

The revised direction, to evaporate at a temperature not exceeding 140° F. (60° C.), instead of "by a current of warm air," is an improvement. *Extract of Socotrine Aloes*, made by a similar process, was dropped at the last revision of the British Pharmacopœia.

Dose, two to six grains (0.13 to 0.4 Gm.).

Off. Prep.—Decoction Aloes Compositum, *Br.*; *Extractum Colocyntidis Compositum, Br.*; *Tinctura Aloes, Br.*

EXTRACTUM ANTHEMIDIS. Br.

EXTRACT OF CHAMOMILE

(*ex-trăc'tum an-thēm'idis*)

Extrait de Camomille Romaine, Fr.; Extractum Chamomillæ Romanæ; Römisch-Kamillenextrakt, G.

"Chamomile Flowers, 1 pound (Imperial) or 1000 grammes; Oil of Chamomile, 15 minims (Imp. meas.) or 2 cubic centimetres; Distilled Water, 1 gallon (Imp. meas.) or 10 litres. Boil the Chamomile Flowers with the Distilled Water until the volume is reduced to one-half; strain; press; filter; evaporate the filtrate to the consistence of a soft extract; add the Oil of Chamomile towards the end of the process." *Br.*

According to Brande, one cwt. of dried chamomile flowers affords upon an average 48 pounds of extract.

This extract has a deep brown color, with the bitter taste and aroma of chamomile. It much better represents the chamomile than did the old Edinburgh extract, which, being obtained by decoction and inspissation, contained none of the volatile oil of the plant. In the present British process care is taken not only to avoid boiling, but also to supply any possible loss of oil during the cautious evaporation, by the addition of a small portion near the close of the process. The extract may be given for the same purpose as the flowers, but is most used as a vehicle for other tonics in the pilular form. An extract may be prepared having the peculiar flavor as well as bitterness of chamomile, by macerating the flowers in water, and evaporating the infusion *in vacuo*.

Dose, two to ten grains (0.13 to 0.65 Gm.).

EXTRACTUM BELLADONNÆ FOLIORUM. U. S. (Br.)

EXTRACT OF BELLADONNA LEAVES

[*Extractum Belladonnæ Foliorum Alcoholicum, Pharm.* 1890]

(*ex-trăc'tum bēl-lā-dōn'næ fō-lī-ō'rūm*)

"An Extract containing one per cent. of the alkaloids of Belladonna Root." *Br.*

Extractum Belladonnæ Alcoholicum, Br.; also *U. S.* 1880; *Extrait de Belladone (Racine), Fr. Cod.*; *Spirituosus Tollkirscheneextrakt, G.*; *Estratto di belladonna idroalcoolicco, It.*; *Extracto alcoholico de belladonna, Sp.*

* "Belladonna Leaves, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of Alcohol with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 fluidrachms] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until *three thousand cubic centimeters* [or 101 fluidounces, 3½ fluidrachms] of tincture are obtained, or the Belladonna Leaves are exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], mix the residue with the reserved portion, and evaporate at or below the above-mentioned temperature to a pilular consistence. When assayed by the process given below, Extract of Belladonna Leaves should contain 1.4 percent. of mydriatic alkaloids. If the Extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.4 percent." U. S.

"Evaporate *one fluid ounce* (Imperial measure) or fifty cubic centimetres of Liquid Extract of Belladonna, in a counterpoised basin, on a water-bath, to the consistence of a moderately firm extract; weigh. The difference between the weight of the residue and *three quarters of an ounce* (Imp.) or thirty-seven and a half grammes gives the weight of Milk Sugar to be used as a diluent for each *fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Liquid Extract.

Evaporate *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of Liquid Extract of Belladonna to the consistence of a thin syrup; add to it the required quantity of Milk Sugar determined from the data obtained from the foregoing experiment; continue the evaporation until the extract weighs *fifteen ounces* (Imp.) or seven hundred and fifty grammes. This Alcoholic Extract of Belladonna contains one-third the proportion of alkaloids present in average samples of the Alcoholic Extract of Belladonna of the British Pharmacopœia of 1885." Br.

The alcoholic extracts of belladonna of the U. S. P. 1880 and 1890 were made from the leaves, in deference to a prejudice which seems to have a strong following. The British Pharmacopœia introduced in the 1885 revision for the first time an alcoholic extract of bella-

donna, but it differed from the U. S. extract in being made from the root instead of the leaves. (See *Extractum Belladonnæ Viride*, p. 471.) The British alcoholic (root) extract (1898) is 66 per cent. weaker than the Br. Pharm. 1885 extract; it now contains 1 per cent. of the alkaloids of belladonna root, and is only 25 per cent. stronger than the liquid extract. While the advantage of establishing a definite relation between the two is apparent, in our opinion it would have been better not to have reduced the strength so enormously as 66 per cent.; the extract could have been made to contain 1½ per cent. of alkaloids, and, besides, this would have conveniently made the extract just double the strength of the liquid extract. The reduction in strength was no doubt made for the purpose of avoiding accidents in dispensing due to having two official Extracts of Belladonna. The dose of both British extracts is now the same. (P. J., 1895, 795.) The absence of chlorophyll in an extract made from the root would cause ointments, cerates, plasters, etc., made from it to be deficient in the characteristic green color so much prized, but there can be no question of the greater uniformity in strength of the root.

Assay. U. S. (8th Rev.)—"Extract of Belladonna Leaves, *five grammes*, Alcohol, Ammonia Water, Distilled Water, Chloroform, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S. or Iodeosin T.S., each, *a sufficient quantity*. Introduce the Extract of Belladonna Leaves into a small beaker and dissolve it in a mixture consisting of alcohol 5 Cc., distilled water 10 Cc., ammonia water 2 Cc., and chloroform 20 Cc. When dissolved, transfer it to a separator, rinsing the beaker with a little alcohol and adding the rinsings to the separator. Insert the stopper securely and shake the separator for half a minute. Draw off the chloroformic layer into a second separator, and add to the first separator 10 Cc. more of chloroform. Shake it for half a minute, allow to separate, and again draw off the chloroformic layer into the second separator. Repeat this with 10 Cc. more of chloroform. To the united chloroformic liquids in the second separator, add 5 Cc. of normal sulphuric acid V.S. and 10 Cc. of distilled water, and shake it for half a minute. Draw off the chloroformic layer, after the liquids have separated, into the first separator, after cleaning it thoroughly, and the aqueous layer into a beaker, and repeat the process by adding to the first separator 10 Cc. of distilled water and 1 Cc. of normal sulphuric acid V.S. Draw off the chloroformic layer, rejecting the same, and then run the acid aqueous layer into the beaker. Pass the combined acid aqueous solutions through a pledget of purified cotton into the first separator, after cleaning it thoroughly, rinsing the second separator, the beaker, and the funnel with about 10 Cc. of distilled water. To the first separator, add 15 Cc. of

chloroform, a small piece of red litmus paper and enough ammonia water to produce a distinctly alkaline reaction. Shake the separator for half a minute, and when the liquids have separated, draw off the chloroformic layer into a beaker. Repeat this process with two portions of 10 Cc. each of chloroform, and evaporate the combined chloroformic liquids in the beaker to dryness on a water-bath containing warm water; dissolve the residue in 3 Cc. of ether and allow the latter to evaporate completely. To the alkaloidal residue add 5 Cc. of tenth-normal sulphuric acid V.S. and 5 drops of hematoxylin T.S. (or iodeosin T.S.), then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0287, and this product by 20, to obtain the percentage of mydriatic alkaloids contained in the Extract of Belladonna Leaves. The figure 0.0287 represents the weight in grammes of mydriatic alkaloids (mainly atropine) required to neutralize 1 Cc. of tenth-normal sulphuric acid V.S." U. S.

Uses.—The formula for this extract does not differ essentially from that official in the former revision; it is a good preparation, and is official in the French Codex. It is much used externally. Thus, in *rigidity of the os uteri*, it is applied at intervals to the neck of the uterus, mixed with simple ointment in the proportion of one drachm to an ounce; but care must be taken not to affect the system too powerfully, and the preparation, therefore, should be used in a small quantity at first. In *irritability of the bladder, choræe, spasm of the urethra or of the rectum*, it may either be rubbed in the form of ointment upon the perineum, or be used in the form of suppository; but care is requisite not to introduce it too freely into the bowel. It is sometimes smeared upon the bougie, mixed with oil, in the treatment of stricture of the urethra. In the form of ointment it has been beneficially employed in *phimosis* and *paraphimosis*, and in that of plaster or ointment, in local *neuralgic or rheumatic pains*. (See *Emplastrum Belladonnæ*.)

Dose, internally, from one-sixth to one-third of a grain (0.010 to 0.021 Gm.).

Off. Prep.—*Emplastrum Belladonnæ*, U. S.; *Pilule Laxativæ Compositæ*, U. S.; *Pilule Podophylli*, *Belladonnæ et Capsici*, U. S.; *Suppositoria Belladonnæ*, Br.; *Unguentum Belladonnæ*, U. S.

EXTRACTUM BELLADONNÆ VIRIDE. Br.

GREEN EXTRACT OF BELLADONNA

(*ex-trac'tum bēl-lā-dōn'næ vīr'i-dē*)

"Bruise the fresh leaves and young branches of *Atropa Belladonna*, *Linn.*, in a mortar;

press out the juice and heat it to 130° F. (54.4° C.); separate the green coloring matter by a calico filter; heat the strained liquid to 200° F. (93.3° C.); filter. Evaporate the filtrate on a water-bath to the consistence of a thin syrup; add to it the green coloring matter previously separated and passed through a hair sieve, stir the whole together, and evaporate at a temperature not exceeding 140° F. (60° C.) to the consistence of a soft extract." Br. This extract is identical with the Br. Pharm. 1885 extract of belladonna leaves made from the recent plant.

Dose, from one-fourth to one grain (0.016 to 0.065 Gm.).

EXTRACTUM CANNABIS INDICÆ.

U. S., Br.

EXTRACT OF INDIAN CANNABIS

(*ex-trac'tum cân-na-bis in'di-cæ*)

Extract of Indian Hemp; *Extrait de Chanvre de l'Inde*, Fr. Cod.; *Indischer Hanfextrakt*, G.

* "Indian Cannabis, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity. Moisten the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Indian Cannabis is exhausted. Distil off the Alcohol from the percolate by means of a water-bath, and evaporate the residue, in a porcelain dish, on a water-bath, to a pilular consistence." U. S.

"Exhaust Indian Hemp, in coarse powder, with Alcohol (90 per cent.) by percolation; evaporate the percolate to the consistence of a soft Extract." Br.

It will be noticed that the English name of the drug was changed in the U. S. Pharmacopœia 1890 to Indian Cannabis, to prevent its being mistaken for the root of *Apocynum cannabinum*, which is also called Indian Hemp. Several mistakes have occurred through this unfortunate confusion of nomenclature.

Although there is some difference in the details of the two processes, the preparations of the U. S. and Br. Pharmacopœias are practically identical. Procter investigated the subject of the tests for the purified extract or resin, and came to the following conclusions: its peculiar odor when moderately heated, its indifference to alkalies, and its solubility in alcohol, ether, chloroform, benzene, and oil of turpentine are characteristic though not entirely distinctive properties. The best test, he found, was nitric

acid (sp. gr. 1.38), which acts slowly when cold, but with heat rapidly, evolving red fumes, and converting the resin into an orange-red resinoid substance which, when washed and dried, closely resembles gamboge in color. (*Proc. A. Ph. A.*, 1864.) Care should be observed in selecting the drug for making this extract, and old Indian cannabis should be rejected. The limit of age in India is said to be three years. (*P. J.*, 1894, 246; *Rép. de Pharm.*, 1894, 257.) The preparation varies exceedingly in strength, so that it is wisest to begin with a small *dose*, one-quarter of a grain (0.016 Gm.), and rapidly increase the amount given until some effect is produced.

Off. Prep.—Tinctura Cannabis Indicæ, Br.

EXTRACTUM CIMICIFUGÆ. U. S.

EXTRACT OF CIMICIFUGA

(ex-trăc'tûm cîm-î-clîf'û-gæ)

Extract of Black Cohosh; Extrait d'Actée à grappes, Fr.; Cimicifugaextract, G.

* "Fluidextract of Cimicifuga, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Glycyrrhiza (peeled, Russian), in No. 80 powder, a sufficient quantity, to make twenty-five grammes [or 386 grains]. .. Evaporate the Fluidextract of Cimicifuga in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring, to complete dryness. Reduce the product to a fine powder and add enough powdered Glycyrrhiza to make the finished Extract weigh twenty-five grammes [or 386 grains]. Mix thoroughly." U. S.

This extract was introduced for the reason that although the fluidextract and tincture represent the virtues of cimicifuga, the alcohol present in both is therapeutically contra-indicated, and the exceedingly disagreeable taste of the drug is entirely masked if the extract be prescribed in the form of a pill, with proper additions, such as extract of licorice, or if the pill be coated or enclosed in a capsule.

Dose, of the extract, from three to ten grains (0.2 to 0.65 Gm.).

EXTRACTUM COLCHICI. Br.

EXTRACT OF COLCHICUM

(ex-trăc'tûm cöl'çhî-cî)

"Crush fresh Colchicum Corms, deprived of their coats; press out the juice; allow the feculence to subside; decant; heat the clear liquid to 212° F. (100° C.); strain through flannel, and evaporate at a temperature not exceeding 160° F. (71° C.) to the consistence of a soft extract." Br.

The U. S. extract is an acetic extract of the corm (see *Extractum Colchici Cormi*); the British is made by evaporating the juice of fresh corms.

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims (0.3 Cc.) or more. It is made by expressing the fresh corm, allowing the juice to stand for forty-eight hours that the feculent matter may subside, then adding one-fourth of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering.

Dose, of the British extract, from fresh corms, one to two grains (0.065 to 0.13 Gm.).

EXTRACTUM COLCHICI CORMI. U. S.

EXTRACT OF COLCHICUM CORM

[*Extractum Colchici Radicis*, Pharm. 1890, Acetic Extract of Colchicum]

(ex-trăc'tûm cöl'çhî-cî cör'mî)

Extrait de Colchique acetique, Fr.; Zeitlosen Essigextract, G.

* "Colchicum Corm, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Acetic Acid, three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims]; Water, a sufficient quantity. Mix the Acetic Acid with fifteen hundred cubic centimeters [or 50 fluidounces, 346 minims] of Water, and, having moistened the powder with five hundred cubic centimeters [or 16 fluidounces, 436 minims] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Water, until the Colchicum Corm is exhausted. Evaporate the percolate in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 80° C. (176° F.), to a pilular consistence.

When assayed by the process given below, Extract of Colchicum Corm should contain 1.4 percent. of colchicine. If the Extract should be found by assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.4 percent." U. S.

Assay. U. S. (8th Rev.)—"Extract of Colchicum Corm, four grammes, Chloroform, Alcohol, Ether, Distilled Water, Ammonia Water, each, a sufficient quantity. Dissolve the Extract of Colchicum Corm in 20 Cc. of distilled water, carefully transfer the solution to a graduated flask, and add sufficient alcohol to make the liquid measure 100 Cc. Shake the flask well, allow it to stand for five minutes,

filter, and collect 50 Cc. of the filtrate (representing 2 Gm. of the Extract), and evaporate it to dryness in a porcelain dish by means of a water-bath. Add to the residue 10 Cc. of ether and 5 Cc. of distilled water, stir the mixture well and heat it gently until the ether is evaporated. After cooling, pour off the aqueous solution, filtering it into a separator, retaining as much of the insoluble matter in the dish as possible. Again treat the residue with 10 Cc. of ether, and 5 Cc. of water, and proceed as before; rinse the dish and filter with a little water and collect all of the aqueous liquids in the separator. Introduce a small piece of red litmus paper into the separator, add enough ammonia water to render the liquid alkaline, and then shake it out with three successive portions of chloroform, of 20, 15, and 10 Cc., respectively. Collect the combined chloroformic solutions in an Erlenmeyer flask, evaporate the chloroform, and add to the alkaloidal residue two successive small portions of alcohol, evaporating the alcohol each time. Now add to the residue a mixture of 5 Cc. of distilled water and 10 Cc. of ether, agitate the liquid gently and evaporate the ether; after cooling, filter the aqueous liquid into a separator. Rinse the flask with distilled water, pass the rinsings through the filter into the separator, and shake out the aqueous solutions with three successive portions of chloroform, 20, 15, and 10 Cc. respectively. Collect the combined chloroformic solutions in a tared Erlenmeyer flask, evaporate the chloroform, and treat the alkaloidal residue with two successive small portions of alcohol, evaporating the alcohol each time, and dry the residue, at 100° C. (212° F.), to a constant weight. The weight multiplied by 50 will give the percentage of colchicine in the Extract of Colchicum Cormi." *U. S.*

As the fresh colchicum corm is rarely to be had in this country, the *U. S. Pharmacopœia* employs the dried corm; its process, if properly conducted, will afford a very efficient extract. In preparing this extract according to the British process, by expression from the recent corm, there will be experienced some inconveniences, which would seem to render the *U. S.* process under all circumstances preferable. (*P. J.*, xiii. 62.) The acetic extract of colchicum made from fresh corms was abandoned by the *Br. Ph.* 1898. The acetic acid menstruum in the *U. S.* preparation is a good solvent for colchicine.

Dose, from one-fourth to one grain (0.016 to 0.065 Gm.).

EXTRACTUM COLOCYNTHIDIS. *U. S.*

EXTRACT OF COLOCYNTH

(*ex-trăc'tūm cōl-q-cyn'thi-dis*)

Extractum Colocynthis Alcoholicum; Extrait de Coloquinte, Fr. Cod.; Extractum Colocynthis, P. G.; Koloquintenextrakt, G.; Estratto di colouintide idroalcolico, It.

* "Colocynth, freed from the seeds, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity. Reduce the Colocynth to a coarse powder by grinding or bruising, and macerate it in thirty-five hundred cubic centimeters [or 118 fluid-ounces, 167 minims] of Diluted Alcohol for four days, with occasional stirring; then express strongly, and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and gradually pour Diluted Alcohol upon it until the tincture and expressed liquid, mixed together, measure five thousand cubic centimeters [or 169 fluidounces, 33 minims]. Distil off the Alcohol from the mixture by means of a water-bath, evaporate the residue to dryness, and reduce the dry mass to powder. Extract of Colocynth should be kept in well-stoppered bottles." *U. S.*

The colocynth should always be deprived of its seeds, following the directions of the *U. S. Pharmacopœia*, before being submitted to the action of the menstruum. Duncan found 3500 grains of colocynth to contain 2770 grains of seeds, which, when they were boiled by themselves, yielded almost nothing to water. Squibb found selected fruits to yield from 25.8 to 34 per cent. of medullary part, and this, when well exhausted by diluted alcohol, was found to yield 60.7 to 60.8 per cent. of dry extract, while from the whole fruit, including pulp and seeds, from 15.69 to 20.6 per cent. was obtained, according to the degree of dryness. (*A. J. P.*, 1857, p. 98.) Boiling water extracts such a large amount of pectin and mucilage from colocynth that either the decoction or the hot infusion "gelatinizes on cooling, and the extract made by means of it is therefore loaded with inert matter, and, besides, is liable to become mouldy, or so tough and hard as to resist trituration and formation into pills. Hence many years ago the London College, following in this respect the old French Codex, directed, in the last edition of its *Pharmacopœia*, maceration with cold water; but diluted alcohol has been found to be a much better menstruum, and has accordingly been adopted in the *U. S. Pharmacopœia* process, while in the British *Pharmacopœia* the simple extract has been discarded altogether. The chief, if not exclusive, use of the alcoholic extract is in the preparation of the compound extract.

This preparation should never be substituted for an extract prepared with a menstruum containing a larger percentage of water, because the water extracts a large quantity of mucilaginous and inert matter. Commercial extract of colocynth may be often found in the market made with an aqueous menstruum.

Dose, one-half grain (0.032 Gm.).

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. U. S., Br.

COMPOUND EXTRACT OF COLOCYNTH

(*ex-trăc'tūm cōl-q-cyn'thī-dis cōm-pōs'it-ūm*)

Extrait de Coloquinte composé, *Fr.*; Zusammen-
gesetztes Colokynthentextrakt, *G.*

* "Extract of Colocynth, *one hundred and sixty grammes* [or 5 ounces av., 282 grains]; Purified Aloes, *five hundred grammes* [or 17 ounces av., 279 grains]; Cardamom, in No. 60 powder, *sixty grammes* [or 2 ounces av., 51 grains]; Resin of Scammony, in fine powder, *one hundred and forty grammes* [or 4 ounces av., 411 grains]; Soap, dried and in coarse powder, *one hundred and forty grammes* [or 4 ounces av., 411 grains]; Alcohol, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Heat the Purified Aloes, contained in a suitable vessel, on a water-bath, until it is completely melted; then add the Alcohol, Soap, Extract of Colocynth, and Resin of Scammony, and heat the mixture at a temperature not exceeding 120° C. (248° F.), until it is perfectly homogeneous, and a thread taken from the mass becomes brittle when cool. Then withdraw the heat, thoroughly incorporate the Cardamom with the mixture, and cover the vessel until the contents are cold. Finally, reduce the product to a fine powder. Compound Extract of Colocynth should be kept in well-stoppered bottles." *U. S.*

"Colocynth Pulp, 6 ounces (Imperial) or 150 grammes; Extract of Barbados Aloes, 12 ounces (Imp.) or 300 grammes; Scammony Resin, 4 ounces (Imp.) or 100 grammes; Curd Soap, in shavings, 4 ounces (Imp.) or 100 grammes; Cardamom Seeds, in the finest powder, 1 ounce (Imp.) or 25 grammes; Alcohol (60 per cent.), 1 gallon (Imp. meas.) or 4 litres. Macerate the Colocynth Pulp in the Alcohol for four days; press out the tincture; remove the alcohol by distillation; add the Extract of Aloes, Scammony Resin, and Soap; evaporate to the consistence of a firm extract, adding the Cardamoms towards the end of the process." *Br.*

The *Br.* Pharm. (1898) substituted Barbados aloes for the Socotrine variety, and increased the proportion of soap from three to four ounces. The object of the soap is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the liquors of the stomach. It may possibly also serve the purpose of qualifying the action of the aloes. In the *U. S.* process the extract is in the form of powder, which is very convenient for admixture with other substances; while if given uncombined, it may be readily made into pills by suitable additions. The alternative of using the scammony or its resin, in the first British formula, which appeared to us very objectionable, has been abandoned in the present edition, and the resin only directed. It was objected to the *U. S.* com-

pound extract of 1860 that it was apt to gripe in consequence of deficiency in the proportion of the aromatic ingredient, and the addition of some aromatic oil, as oil of cloves, was recommended; this was remedied in the revision of 1870 by increasing the proportion of cardamom. The plan of having the powders simply mixed was liable to the objection that the mixture was not likely to be so thoroughly effected as to obtain a uniform result, and hence the *U. S. Pharm.* 1880 adopted Squibb's suggestion, to melt together all the ingredients unpowdered, except the cardamom, add a little alcohol, and, when the mixture is thoroughly made, to stir in the powdered aromatic, and finally to reduce the whole to a fine powder. The active principle of the cardamom (the volatile oil) is thus not dissipated, but absorbed by the other ingredients, and one of the objections to the British process is avoided,—*i.e.*, the necessity for directing cardamom in "the finest" powder, the previous desiccation of the cardamom, which is a requisite if a fine powder is desired, being very wasteful of the volatile oil.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, etc., with one or more of which it is often united in prescription. We are informed that much of the extract sold in this country is made with inferior scammony and aloes and an insufficient proportion of colocynth, so that it is comparatively inert. Compound extract of colocynth should be looked on with suspicion when cheap, and the pharmacist should always prepare it for himself. (*See Am. Drug.*, 1896, 152.)

Dose, as a laxative, one to two grains (0.065 to 0.13 Gm.); as a purgative, five to ten grains (0.32 to 0.65 Gm.).

Off. Prep.—Pilulæ Catharticæ Compositæ, *U. S.*; Pilulæ Catharticæ Vegetabiles, *U. S.*

EXTRACTUM DIGITALIS. U. S.

EXTRACT OF DIGITALIS

(*ex-trăc'tūm dig-ī-tāl'is*)

Extractum Digitalis Alcoholicum; Extrait de Digitale (alcoolique), *Fr. Cod.*; Digitalisextrakt; Fingerhutextrakt, *G.*; Estratto di digitale idroalcolico, *It.*; Extracto alcohólico de digital, *Sp.*

* "Fluidextract of Digitalis, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Evaporate the Fluidextract of Digitalis in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), with constant stirring, until it is reduced to a pilular consistence." *U. S.*

This was first introduced into the *U. S. Pharmacopœia* of 1860, though less needed than many others, because the dose of digitalis itself is small, and very little can be gained on

the point of strength. The alcoholic extract of digitalis contains all the virtues and may be used for all the purposes of the powdered leaves. According to Vielguth and Nentwich, the amount of alcoholic extract obtained from dried digitalis by cold displacement is 27.1 per cent. (*A. J. P.*, May, 1859.)

Dose, one-fourth of a grain (0.016 Gm.).

EXTRACTUM ERGOTÆ. U. S., Br.

EXTRACT OF ERGOT

(*ex-trăc'tūm ěr-gō-tă*)

Extractum Hæmostatium; Ergotin, Br. (1898); *Extrait de Segle Ergoté, Fr. Cod.*; *Extractum Secalis cornuti, P. G.*; *Mutterkornextrakt, G.*; *Estratto di segala cornuta, It.*

*“Ergot, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Hydrochloric Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Monohydrated Sodium Carbonate, *eight and one-half grammes* [or 131 grains]; Glycerin, *twelve and one-half grammes* [or 193 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]. Mix *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Alcohol with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water, and, having moistened the powder with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of the mixture, pack it firmly in a cylindrical percolator; then add sufficient menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Ergot is exhausted. Evaporate the percolate in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), to *two hundred and fifty grammes* [or 8 ounces av., 358 grains]; add *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of water, and stir; filter when cold, rinse the dish with a little Water, and add this to the filter. Add the Diluted Hydrochloric Acid to the filtrate; then set it aside for twenty-four hours; filter, wash the contents of the filter with Water until the washings no longer have an acid reaction, and add the washings to the filtrate. To this, add gradually the Monohydrated Sodium Carbonate, and, when the evolution of carbon dioxide has ceased, evaporate the liquid in a tared dish until it weighs *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; add the Glycerin, and continue the evaporation, at the above-named temperature, until the weight of the Extract is reduced to *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains].” U. S.

“Ergot, in No. 40 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (60 per cent.), *a sufficient quantity*; Distilled Water, *a sufficient quantity*; Diluted Hydrochloric Acid, 7½ fl. drachms (Imp. meas.) or 47 cubic centimetres; Sodium Carbonate, 175 grains (Imp.) or 20 grammes. Moisten the powdered Ergot with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; pack the damp powder in a percolator; percolate with the Alcohol until the Ergot is exhausted. Evaporate the percolate to *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres; add *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of Distilled Water; filter when cold, washing the residue with a little Distilled Water. Add the Diluted Hydrochloric Acid to the filtrate; set aside for twenty-four hours; filter; wash the residue with Distilled Water until the washings no longer have an acid reaction, adding the washings to the filtrate; add the Sodium Carbonate to the latter; evaporate to a soft extract.” Br.

This official extract leaves little to be desired. The U. S. and the British preparations are modelled upon Keller's process. (*S. W. P.*, 1894, 141.) The object of the addition of hydrochloric acid is to precipitate out the flocculent sclererythrin, the coloring matter of ergot. The sodium carbonate neutralizes the acid, a small quantity of sodium chloride remaining in the extract. This is much the best preparation of ergot, being the only one that should be used hypodermically, and much less likely to cause nausea when given by the mouth. For method of hypodermic use, see *Ergota*. It is well adapted for suppositories, and has been applied topically to the os uteri, the desired dose being put on a dossil of absorbent cotton. Internally it is best given in gelatin capsules, since pills are likely to flatten.

Dose, from five to fifteen grains (0.32 to 1.0 Gm.).

Off. Prep.—*Injectio Ergotæ Hypodermica, Br.*

EXTRACTUM EUONYMI. U. S. (Br.)

EXTRACT OF EUONYMUS

(*ex-trăc'tūm eū-ōn'y-mī*)

Extractum Euonymi Siccum, Br.; Dry Extract of Euonymus; Extract of Wahoo; *Extrait d'Euonymus atro-purpureus, Fr. Cod.*; *Extrait de Fusain Américain, Fr.*; *Spindelbaumextrakt, Spillbaumrindenextrakt, G.*

*“Fluidextract of Euonymus, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Glycyrrhiza (peeled, Russian), in No. 80 powder, *a sufficient quantity*, to make *twenty-five grammes* [or 386 grains]. Evaporate the Fluidextract of Euonymus in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring, to complete dryness. Reduce the pro-

duct to a fine powder, and add enough powdered Glycyrrhiza to make the finished extract weigh *twenty-five grammes* [or 386 grains]. Mix thoroughly." *U. S.*

"Euonymus Bark, in No. 20 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (45 per cent.), a sufficient quantity; Calcium Phosphate, a sufficient quantity. Moisten the powdered Euonymus Bark with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; pack in a percolator; gradually pour on more of the menstruum until the Euonymus is exhausted; collect the liquid and evaporate the alcohol; thoroughly dry the residue; powder the product as far as possible and mix it with one-fourth of its weight of Calcium Phosphate, continuing the drying and powdering until a satisfactory preparation is obtained; then immediately transfer it to a well-closed bottle." *Br.* Dry and powdered extract of euonymus is frequently but erroneously termed "*euonymin*."

Dose, one to three grains (0.065 to 0.2 Gm.).

EXTRACTUM GENTIANÆ. U. S., Br.

EXTRACT OF GENTIAN

(*ex-trăc'tum gën-ti-ăn'æ*)

Extrait de Gentiane, *Fr. Cod.*; Extractum Gentiane, *P. G.*; Enzianextrakt, *G.*; Estratto di gentiana acquoso, *It.*; Extracto acuoso de gentiana, *Sp.*

* "Gentian, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, a sufficient quantity. Moisten the powder with *four hundred cubic centimeters*. [or 13 fluid-ounces, 252 minims] of Water, and let it macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the Gentian. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then, by means of a water-bath, evaporate to a pilular consistence." *U. S.*

"Infuse Gentian Root in ten times its weight of Distilled Water for two hours; boil for fifteen minutes; pour off; press; strain; evaporate the liquid to the consistence of a soft extract." *Br.*

The plan of percolation with cold water is admirably adapted to the extraction of the active principles of gentian. By the use of cold water, starch and pectic acid are left behind, while any albumen that may be taken up is disposed of by the subsequent boiling and straining.

The extract, however, may be advantageously made by macerating the root in two parts of water for thirty-six hours, then expressing in a powerful press, again macerating with additional water, and in like manner expressing, and evaporating the united expressed liquors. Guibourt and Cadet de Vaux obtained by maceration in cold water an extract not only greater in amount, but also more transparent, more bitter, and possessing more of the color and odor of

the root, than that prepared by decoction. Guibourt attributes this result to the circumstance that, as gentian contains little if any starch, it yields nothing to boiling which it will not also yield to cold water, while decoction favors the combination of a portion of the coloring matter with the lignin. But this opinion requires modification, now that it is understood that gentian contains pectic acid, which water will extract when boiling hot, but not when cold. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian has an agreeable odor, is very bitter, and of a dark brown color approaching to black, shining, and tenacious. It is frequently used as a tonic, in the form of pill, either alone or in connection with metallic preparations; but the practice of some pharmacists of using it indiscriminately as a pill excipient is deserving of severe censure.

Dose, from five to ten grains (0.32 to 0.65 Gm.).

EXTRACTUM GLYCYRRHIZÆ. U. S.

EXTRACT OF GLYCYRRHIZA [Extract of Licorice]

(*ex-trăc'tum glyc-yrrhî-zæ*)

"The commercial extract of the root of *Glycyrrhiza glabra* Linné, or of *Glycyrrhiza glandulifera* Waldstein and Kitaibel (Fam. *Leguminosæ*)." *U. S.*

Extractum Liquiritiæ; Liquorice, Licorice; Extrait de Régilisse, *Fr. Cod.*; Suc de Régilisse, Sucre noir, *Fr.*; Succus Liquiritiæ, *P. G.*; Lakriz, Lakritzensaft, Süßholzsafft, *G.*; Estratto di liquorizia, Sugo di liquorizia, *It.*; Extracto acuoso de regaliz, Regaliza en ballos, *Sp.*

Licorice is an article of export from the north of Spain, particularly Catalonia, where it is obtained in the following manner. The roots of the *G. glabra*, having been dug up, thoroughly cleansed, and half dried by exposure to the air, are cut into small pieces, and boiled in water until the liquor is saturated. The decoction is then allowed to rest, and, after the dregs have subsided, is decanted, and evaporated to the proper consistence. The extract, thus prepared, is formed into rolls from five to six inches long by an inch in diameter, which are dried in the air, and wrapped in laurel leaves.

The British Pharmacopœia gives a process for making extract of licorice. (See page 478.) The U. S. Pharmacopœia directs that not less than 60 per cent. of it should be soluble in cold water.

Much licorice is prepared in Calabria, according to Fée, from the *G. echinata*, which abounds in that country. The process is essentially the same as that just described, but conducted with greater care, and the Italian licorice is purer and more valuable than the Spanish. It is in cylinders, generally somewhat smaller than the Spanish, and usually stamped with the manufacturer's brand. Most of the extract brought to this

country comes from Messina and Catania in Sicily and Naples, from Seville and Saragossa in Spain, and from Smyrna in Turkey. Perhaps in no other part of the world is more licorice consumed than in the United States, from four to five thousand tons having been imported annually before 1860; but the article is now made on an extensive scale in this country, very successfully, with the best modern appliances, and of such good quality as to have almost driven the foreign article out of the market. The principal use of Extract of Licorice is in the manufacture of chewing tobacco, that in the form of rolls as sold by the druggists being a comparatively small portion of the whole amount consumed.

Crude Licorice, Licorice Paste, or Licorice Mass, as it is variously termed, is found in the market in cases ranging from two hundred and fifty to four hundred pounds, of a hard pilular consistence and, as its name implies, in a mass, which has been run into the case while hot and then allowed to cool.

Licorice is usually in cylindrical rolls, somewhat flattened, and often covered with bay-leaves. We have seen it abroad and in this market in large cubical masses. When good, it is very black, dry, brittle, breaking with a shining fracture, of a very sweet, peculiar, slightly acid or bitterish taste, and almost entirely soluble, when pure, in boiling water.

It is described officially as "in flattened cylindrical rolls, from 15 to 18 Cm. long, and from 15 to 30 Mm. thick; of a glossy black color. It breaks with a sharp, conchoidal, shining fracture, and has a very sweet, peculiar taste. Not less than 60 percent. of it should be soluble in cold water." *U. S.* Neumann obtained 460 parts of aqueous extract from 480 parts of Spanish licorice. It is, however, considerably less soluble in cold water. It is often impure from accidental or fraudulent addition or careless preparation. Starch, sand, the juice of prunes, etc., are sometimes added, and carbonaceous matter, and even particles of copper, are found in it, the latter arising from the boilers in which the decoction is evaporated. Four pounds of the extract have yielded two drachms and a half of metallic copper. (Fée.) In different commercial specimens examined by Chevalier he found from 9 to 50 per cent. of insoluble matter. (*J. P. C.*, xxx. 429.) This is by no means, however, always impurity. In the preparation of the extract by decoction, a portion of matter originally insoluble, or rendered so by decoction, is taken up, and is, in fact, necessary to the proper constitution of the licorice. When this is prepared with cold water, or even with hot water by simple displacement, the extract attracts moisture from the air, becomes soft, and loses the characteristic brittleness of the drug. The additional substances taken up in decoction serve to protect the extract against this change. Delondre has obtained the same result by using steam as the solvent. He prepares from the root an

excellent licorice, having all the requisite qualities of color, taste, and permanence, by passing steam, in suitable vessels, through the coarse powder of the root. The vapor thoroughly penetrates the powder, and is drawn off as it condenses. With about 500 lbs. of the root, this treatment is continued for twelve hours, and repeated at the end of five days. The liquors are collected, decanted, clarified with about 4 lbs. of gelatin, and quickly evaporated. After being put into the form of cylinders, the extract is kept for ten days in a drying room, at a temperature of 77° F. (*Ibid.*, p. 433.) A bitter or empyreumatic taste is a sign of inferior quality in licorice. As ordinarily found in commerce, it requires to be purified. (See *Extractum Glycyrrhizæ Purum*; also *Glycyrrhizinum Ammoniatum*.)

Licorice contains *glycyrrhizin*, $C_{24}H_{36}O_9$, a glucoside, partly free and partly in combination with ammonia, to which combination the characteristic sweet taste of licorice is due. The glycyrrhizin when boiled with dilute acids decomposes into *glycyrrhetin*, $C_{18}H_{26}O_4$, and a fermentable sugar.

According to Mellor (*A. J. P.*, 1898, 23, 54, 136) the best process for estimating glycyrrhizin is as follows: The best menstruum with which to treat the commercial powdered extract is a mixture of 40 Cc. ammonia water, 240 Cc. of alcohol, and sufficient water to make a liter. After extraction, filter, and precipitate with diluted sulphuric acid. Of twelve samples examined, the highest was a Greek licorice with 27.78 per cent., and the lowest a Spanish with 5.28 per cent. of glycyrrhizin. Of insoluble matter, the highest was a Spanish with 36.52 per cent., and the lowest a Greek with 5.95 per cent. The average yield, however, was strongly in favor of American licorice. Tobacco manufacturers dissolve 10 Gm. in 100 Cc. of water, add 200 Cc. of alcohol, and allow it to stand over night. The insoluble matter will then have mostly settled; the filtrate is acidulated with sulphuric acid.

The so called *refined licorice*, found in commerce in small cylindrical pieces not thicker than a pipistem, is prepared by dissolving the impure extract in water without boiling, straining the solution, and evaporating. The object of this process is to separate not only the insoluble impurities, but also the acrid oleoresinous substance which is extracted from the licorice root and is necessarily mixed with the unrefined extract. It is customary to add, during the process, a portion of sugar, gum, flour, starch, or perhaps glue. These additions, or something equivalent, are necessary to obviate the deliquescent property of the pure licorice. According to Delondre, 15 per cent. of gum is the proper proportion, when this substance is used; Geiseler has found sugar of milk to lessen the disposition of the extract to absorb moisture; but he considers the best addition, on the whole, to be very finely powdered licorice root, which should be used in the proportion of 1 part to 16 of

the purified extract. (*A. J. P.*, xxviii. 225.) The preparation is sometimes attacked by small worms, probably in consequence of the farinaceous additions. Excellent licorice is prepared in some parts of England, from the root cultivated in that country. The *Pontefract cakes* are small lozenges of licorice made in the vicinity of Pontefract, England. For methods of assaying extract of licorice, see *A. J. P.*, 1896, 663; also 1898, 23, 136.

Uses.—Licorice is a useful demulcent, much employed in cough mixtures, and frequently added to infusions or decoctions in order to cover the taste or obtund the acrimony of the principal medicine. It is used in pharmacy to impart consistence to pills and troches, and to modify the taste of other medicines.

EXTRACTUM GLYCYRRHIZÆ PURUM.

U. S. (Br.)

PURE EXTRACT OF GLYCYRRHIZA

(*ex-trăc'tum glŷc-yr-rhîzæ pû'rûm*)

Extractum Glycyrrhizæ, Br.; Extract of Liquorice; Extractum Glycyrrhizæ Depuratum, Succus Liquiritiæ Depuratus; Extrait de Réglisse pur, *Fr.*; Succus Liquiritiæ depuratus, *P. G.*; Gereinigter Süßholzwass, Reines Lakritz, *G.*

* "Glycyrrhiza, peeled, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Ammonia Water, one hundred and fifty cubic centimeters [or 5 fluidounces, 35 minims]; Glycerin, Distilled Water, each, a sufficient quantity. Mix the Ammonia Water with three thousand cubic centimeters [or 101 fluidounces, 212 minims] of Distilled Water, and, having moistened the powder with one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of the mixture, allow it to macerate in a closed vessel for twenty-four hours. Then pack it moderately in a cylindrical glass percolator, and gradually pour upon it, first the remainder of the menstruum, and then Water, until the Glycyrrhiza is exhausted. Lastly, evaporate the liquid in a tared porcelain dish, by means of a water-bath, to a pilular consistence, and while the mass is still warm, incorporate with it 5 percent. of its weight of Glycerin." *U. S.*

"Liquorice Root, in No. 20 powder, 1 pound (Imperial) or 1000 grammes; Distilled Water, 4 pints (Imp. meas.) or 5 litres. Mix the Liquorice Root with two pints (Imp. meas.) or two and a half litres of the Distilled Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Distilled Water and set aside the mixture for six hours; strain; press; mix the strained liquids; heat to 212° F. (100° C.); strain through flannel; evaporate to the consistence of a soft extract." *Br.*

The necessity for a pure extract of licorice must be apparent to every pharmacist; the very

variable quality of the commercial extract has frequently led to disappointment. The official process affords a preparation which is unexceptionable, the ammonia rendering the glycyrrhizin soluble, yet care must be taken in its evaporation, as it is very easily injured by too much heat, which gives it an empyreumatic taste, destroying at once its usefulness as an agreeable adjuvant.

Off. Prep.—*Confectio Sennæ, Br.*; *Decoctum Aloes Compositum, Br.*; *Mistura Glycyrrhizæ Composita, U. S.*

EXTRACTUM HÆMATOXYLI. U. S.

EXTRACT OF HEMATOXYLON

(*ex-trăc'tum hæ-mă-tôx'y-li*)

Extract of Logwood; Extractum Lignū Campechiani; Extrait de Bois de Campêche, *Fr.*; Campecheholzextract, *G.*

* "Hematoxylon, rasped, one thousand grammes [or 35 ounces av., 120 grains]; Water, ten thousand cubic centimeters [or 338 fluidounces, 66 minims]. Macerate the Hematoxylon with the Water for forty-eight hours. Then boil (avoiding the use of metallic vessels) until one-half of the Water has evaporated; strain the decoction, while hot, and evaporate it to dryness." *U. S.*

This is one of the few instances in which decoction in the preparation of extracts is not considered objectionable. Iron vessels should not be employed in the process, in consequence of the presence of tannic acid. The evaporation should be carried so far that the extract may be dry and brittle when cold. About 20 lbs. of it are obtained from one cwt. of logwood. (Brande.) It is of a deep ruby color, and an astringent, sweetish taste, and has all the medicinal virtues of the wood. If given in pills, these should be recently made, as when long kept they are said to become so hard as sometimes to pass unchanged through the bowels. The extract, however, is best administered in solution. This extract is said to be prepared largely in Yucatan and other parts of Mexico.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

EXTRACTUM HYOSCYAMI. U. S. (Br.)

EXTRACT OF HYOSCYAMUS

(*ex-trăc'tum hŷ-qs-cŷ'ă-mŷ*)

Extractum Hyoscyami Viride, Br., Green Extract of Hyoscyamus; Extract of Henbane; Extrait de Jusquame (feuille), *Fr. Cod.*; Extractum Hyoscyami, *P. G.*; Bilsenkrautextrakt, *G.*; Estratto di glusquiamo idroalcoolico, *It.*; Extracto alcoholico de beleno, *Sp.*

* "Fluidextract of Hyoscyamus, one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Evaporate the Fluidextract of Hyoscyamus in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence.

When assayed as directed below, Extract of Hyoscyamus should contain 0.3 percent. of mydriatic alkaloids. If the Extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 0.3 percent." *U. S.*

Assay. *U. S.* (8th Rev.)—"The method to be employed is identical with that given for Extract of Belladonna Leaves, page 470, using *ten grammes* of Extract of Hyoscyamus instead of the quantity of Extract of Belladonna Leaves there directed, and multiplying the product by 10 instead of 20." *U. S.*

"Bruise fresh leaves, flowering tops, and young branches of *Hyoscyamus niger*, *Linn.*; press out the juice and heat it gradually to 130° F. (54.4° C.); separate the green coloring matter by a calico filter; heat the strained liquid to 200° F. (93.3° C.); filter. Evaporate the filtrate to the consistence of a thin syrup; add to it the green coloring matter previously separated and passed through a hair sieve; stir the whole together, and evaporate at a temperature not exceeding 140° F. (60° C.), to the consistence of a soft extract." *Br.*

Solon and Soubeiran have shown that the insoluble matter separated from the expressed juice of hyoscyamus by filtering, and that coagulated by heat, are nearly if not quite inert; so that the juice may be usefully clarified before evaporation. (*A. J. P.*, viii. 228.) The retention of the chlorophyll, however, as provided for in the British formula, is thought to be advantageous. This kind of extract of hyoscyamus is chiefly derived from England. Brande says that one cwt. of the fresh herb affords between four and five pounds. Recluz obtained one part from sixteen.

The extract is of a dark olive color, of a narcotic rather unpleasant odor, and a bitterish, nauseous, slightly saline taste. It retains its softness for a long time, but at the end of three or four years becomes dry, and exhibits, when broken, small crystals of potassium nitrate and sodium chloride. (Recluz.) Like all the inspissated juices, it is of variable strength, according to its age, the care used in its preparation, and the character of the leaves. (See *Hyoscyamus*.)

Much depends on the choice of the leaves, and too little attention is paid to this point. In reference to the biennial plant, there seems to be no doubt that the leaves of the second year are much more efficacious than those of the first, and should, therefore, always be selected. It is stated under *Hyoscyamus* that the leaves should be gathered soon after the plant has flowered. Charles Cracknell gives more particular directions. He thinks the plant is in a fit state for collection during only a very short period, namely, when the flowers at the top are blown, but have not yet begun to fade, and the seed vessels and seeds which have been formed are still soft and juicy. For other observations on the preparation of this extract, see a paper by

Cracknell in *A. J. P.* (xxiii. 245). T. B. Groves found that an extract obtained by inspissating the juice of the stems was altogether inferior to another obtained in like manner from the leaves, being not only less in amount, but also lower in quality. (*P. J.*, 1862.)

The *U. S. P.* extract is a much more reliable and active preparation than the inspissated juice, or, as it is usually termed, English extract. It is of a dark olive color, with the peculiar odor of hyoscyamus. In the use of the English extract it is advisable to begin with a moderate dose, two or three grains (0.13 or 0.2 Gm.), and gradually to increase the quantity until some effect is experienced, and the degree of efficiency of the particular parcel employed is ascertained. It is usually given in pill.

Dose, from one to two grains (0.065 to 0.13 Gm.).

EXTRACTUM JALAPÆ. Br.

EXTRACT OF JALAP

(ex-trăc'tum ja-lă'pæ)

Extrait de Jalap, *Fr.*; Jalapenextrakt, *G.*

"Jalap, in coarse powder, 1 pound (Imperial) or 1000 grammes; Alcohol (90 per cent.), 4 pints (Imp. meas.) or 5 litres; Distilled Water, 1 gallon (Imp. meas.) or 10 litres. Macerate the powdered Jalap in the Alcohol for seven days; press out the tincture, filter, and then remove the alcohol by distillation, leaving a soft extract. Again macerate the residue of the Jalap in the water for four hours; express; strain through flannel; evaporate to the consistence of a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° F. (60° C.) to the consistence of a firm extract." *Br.*

This extract was retained in the *U. S. Pharmacopœia* of 1890, but was dismissed in the Eighth Revision owing to the fact that the resin of jalap (see *Resina Jalapæ*) represents more fully the activity of the drug and both were not needed. It was intended to replace the abstract formerly official. The *U. S.* 1890 extract was simply an alcoholic extract, differing from the extract official in 1870, and also from the present British extract, in containing no aqueous extract whatever. (See page 468.)

Jalap contains a considerable quantity of starch, which is extracted by decoction, but left behind by cold water, and, as this principle serves only to impede the filtration or straining, and to augment the bulk of the extract, without adding to its virtues, cold water is very properly used in the process, if water is used at all. The use both of alcohol and of water was formerly deemed necessary, in order to extract all the medicinal qualities of the drug, and they were employed successively, under the impression that

the previous removal of the resin by the former facilitates the action of the latter; but A. B. Taylor satisfactorily determined that the substance which water will extract from jalap previously exhausted by alcohol has no observable influence on the system, he having taken 240 grains of the matter thus extracted without effect. (*Proc. A. Ph. A.*, 1864, p. 215.) It was shown, moreover, that the aqueous extract of jalap is hygroscopic, and that it is the cause of the inconvenient hardening of the powdered extract. The substitution of dried sugar of milk for the inert, hygroscopic, aqueous extract was certainly an improvement (see *Abstracts*, page 466); but the use of alcohol alone as a menstruum in the U. S. P. 1890 process made a stronger preparation, and thus a smaller pill could be made in all cases where extract of jalap was prescribed. According to Cadet de Gassicourt, water at ordinary temperatures, and in the old mode, acts so slowly that fermentation takes place before the active matter is all dissolved. Hence, if the extract be prepared without percolation, the residue, after the tincture has been decanted, should be digested with water at a temperature of about 90° or 100° F., which, while it is insufficient for the solution of the starch, enables the solvent to take up the active matter with a sufficient degree of rapidity.

One cwt. of jalap afforded, according to Brande, about fifty pounds of aqueous extract and fifteen of resin. The product of the former was somewhat less by infusion than by decoction, and the extract was proportionately stronger. There is reason to believe, as we have been informed on good authority, that what is sold for extract of jalap is sometimes prepared from tubers which have been previously exhausted of their resin by alcohol, and a spurious substance has been offered in considerable quantities in our markets for extract of jalap, which Bullock and Parrish proved to owe its purgative property to 42 per cent. of gamboge. (*A. J. P.*, 1862, p. 113.)

Extract of jalap is of a dark brown color, slightly translucent at the edges, and tenacious when not perfectly dry. It contains the resin and gummy extractive, and, consequently, has all the medicinal properties of the root; but it is not often exhibited alone, being chiefly used as an ingredient of purgative pills, for which it is adapted by its comparatively small bulk. It is most conveniently kept for use in the form of powder, which, however, is apt to attract moisture and to aggregate into a solid mass, unless carefully excluded from the air.

Dose, from two to eight grains (0.13 to 0.5 Gm.).¹

EXTRACTUM KRAMERIÆ. U. S., Br.

EXTRACT OF KRAMERIA

(*ex-trăc'tum kṛa-mē'ri-æ*)

Extract of Rhatany; Extractum Ratanhæ; Extrait de Ratanhia, *Fr. Cod.*; Ratanhaextrakt, *G.*; Estratto di ratania acquoso, *It.*; Extracto acuoso de ratania, *Sp.*

* "Krameria, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Water, a sufficient quantity. Moisten the powder with three hundred cubic centimeters [or 10 fluid-ounces, 69 minims] of Water, pack it in a conical glass percolator, and gradually pour Water upon it, until the infusion passes but slightly imbued with the astringency of the Krameria. Heat the liquid to the boiling point, strain, and evaporate the strained liquid, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), to dryness." *U. S.*

"Macerate coarsely powdered Krameria Root in twice its weight of Distilled Water for twenty-four hours; pack in a percolator; and percolate with more Distilled Water until the Krameria Root is exhausted. Evaporate the liquid to dryness." *Br.*

In selecting a plan for the preparation of this extract, it was undoubtedly wise to adopt percolation, with cold water as the menstruum. It is absolutely necessary to the success of the process that the root should be well and uniformly comminuted; the "No. 40 powder" of the U. S. Pharmacopœia is, therefore, preferable to the "coarse powder" of the British. The wood of the root yielded to Procter only 6.8 per cent. of extract, while the bark separated from the wood yielded 33 per cent. As the wood is of difficult pulverization, the inference is obvious that, in powdering the roots, the ligneous portion may be rejected with advantage. (*A. J. P.*, xiv. 270.) As a prolonged exposure of the infusion to the air is attended with the absorption of oxygen and the production of insoluble apotheme, it is desirable that the evaporation should be conducted rapidly, or in a vacuum. There scarcely appears to be occasion, in the case of rhatany, for heating and filtering the infusion before evaporation, the only use of which is to get rid of albumen, and this is not among the recognized ingredients of the root.

Very inferior extracts of rhatany are often sold. Such is the South American extract, which has been occasionally imported. As the product obtained by decoction is greater than that afforded by the official plan, the temptation to substitute the former is not always resisted, although it has been shown to contain nearly 50

¹ *Fluidextract of Jalap*.—The following process has been proposed by Procter. Take of jalap, in coarse powder, 16 troyounces; sugar, 8 troyounces; potassium carbonate, half a troyounce; alcohol, water, each, q. s. Add to the jalap one pint of a mixture consisting of two parts of alcohol and one of water, and set aside for twenty-four hours. Then put the mixture into a percolator, and pour on it diluted alcohol until half a gallon has passed. Evap-

orate the filtered liquid one-half, add the sugar and potassium carbonate, and evaporate to 12 fluidounces. Put the liquid, while warm, into a pint bottle, add four fluidounces of alcohol, and mix. The potassium carbonate renders the resin soluble in water, and probably favorably qualifies the irritating properties of the jalap. A fluidrachm of this extract would represent a drachm of jalap, so that the dose should be from 15 to 30 minims (0.9 to 1.8 Cc.). (*A. J. P.*, xxix. 108.)

per cent. of insoluble matter. Some druggists prepare the extract with an alcoholic menstruum, with a view to the greater product, but the extract thus prepared has from 20 to 30 per cent. less of the active principle than the official. A substance has been shown to us, said to have been imported as extract of rhatany from Europe, which was nearly tasteless, and was plausibly conjectured to be the dried coagulated matter of old tincture of kino.

Extract of krameria should have a reddish-brown color, a smooth shining fracture, and a very astringent taste, and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed.

Dose, from five to twenty grains (0.32 to 1.3 Gm.).

Off. Prep.—Trochisci Krameriaë, U. S. (Br.); Trochiscus Krameriaë et Cocainæ, Br.

EXTRACTUM LEPTANDRÆ. U. S.

EXTRACT OF LEPTANDRA

(ex-trăc'tūm lep-tăn'dræ)

Extract of Culver's Root; Extrait de Leptandra, Fr.; Leptandrawurzelextrakt, G.

* "Fluidextract of Leptandra, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Glycyrrhiza (peeled, Russian), in No. 80 powder, a sufficient quantity, to make *twenty-five grammes* [or 386 grains]. Evaporate the Fluidextract of Leptandra in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring, to complete dryness. Reduce the product to a fine powder and add enough powdered Glycyrrhiza to make the finished Extract weigh *twenty-five grammes* [or 386 grains]. Mix thoroughly." U. S.

This extract will furnish practitioners who have been in the habit of prescribing the so-called *leptandrin*, with a uniform preparation.

Dose, from five to ten grains (0.32 to 0.65 Gm.).

Off. Prep.—Pilulæ Catharticæ Vegetabiles, U. S.

EXTRACTUM MALTI. U. S.

EXTRACT OF MALT

(ex-trăc'tūm māl'ti)

Essence (Extrait) de Malt, Fr.; Malzextrakt, G.

* "Malt, in coarse powder, not finer than No. 12, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, a sufficient quantity. Upon the powder, contained in a suitable vessel, pour *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water, and macerate for six hours. Then add *four thousand cubic centimeters* [or 135 fluidounces, 122 minims] of Water, heated to about 30° C. (86° F.), and digest for an hour at a temperature not exceed-

ing 55° C. (131° F.). Strain the mixture with strong expression. Finally, by means of a water-bath, or vacuum apparatus, at a temperature not exceeding 55° C. (131° F.), evaporate the strained liquid rapidly to the consistence of thick honey.

Extract of Malt should be kept in well-closed vessels, in a cool place." U. S.

Under the name of extract of malt, two distinct preparations have been put upon the market, the one being a very strong beer, the other an extract prepared from malt, and chiefly composed of dextrin and glucose, with some albumen and phosphates. The object of the U. S. process is to obtain all of the soluble principles of malt in a permanent form. To secure this, strict attention to the details of the process is necessary. Good extract of malt should contain no starch, have the consistence of thick honey, a brown color, and should be free from empyreumatic taste. A great deal of commercial extract of malt is adulterated with glucose to a surprising extent.

The above process does not differ materially from that of L. W. Jassey (*J. P. C.*, 4e sér., xvi. 440), who recommends the following method.¹ Macerate malt for three hours in its weight of cold water, then add four times its weight of water, and carefully raise the temperature to 65° C. during one hour. Filter, boil the residue with three parts of water for a quarter of an hour, remove from the fire, and allow to cool to 75° C., filter, and express the residue. Mix the liquids, maintain for some time at a temperature of 50° C., until the starch is converted into sugar. Reduce to one-third the volume by gentle boiling, allow to stand over night, filter through a woollen strainer, and evaporate upon a water bath to the consistence of an extract. A dry extract of malt has come into extensive use as an infants' food, made by artificially drying the thick syrupy extract. It is in the form of a straw-colored, coarse powder, and is given dissolved in milk or water. O. F. Romer and H. R. Randoll of Brooklyn, have patented several improvements in the process of making extract of malt,—namely, 1, the properly ground malt is treated with an alkaline solution, in order to neutralize the fatty acids which usually impart a bad taste to the product; 2, the extract is separated from the solid matters by pressing in press cloths, where-

¹ Fellerer recommends the following as being a practical method for the production of malt extract: 1 kilo of malt is broken up and mixed with 1500 Cc. of water of 50° C. and 10 drops of concentrated hydrochloric acid. The mash must be kept for two hours at a temperature of 45° C., after which 3500 Cc. of water at 65° C. is added. After two hours, during which time the temperature must be kept at 60°, it is strained, the liquid filtered through coarse cloth and evaporated *in vacuo*. Malt extract prepared in this way is darker than the usual preparations in the market (which are often clarified by means of albumin), but is sweet and pleasant to the taste. If a lighter color is desired, the temperature should not be allowed to rise above 45° to 50° C.; this has, however, the disadvantage of producing an extract of less sweetness. The hydrochloric acid aids the diastasic action very materially. (*Ph. Zig.*, 1897, 897.)

by it is obtained as a clear liquid with scarcely any loss. (*N. R.*, 1880, 179.) Pharmaceutically, extract of malt has been used as an emulsifying agent; it makes a good basis for a cod liver oil emulsion, for which purpose it is admirably adapted therapeutically.

Dose, from one to four fluidrachms (3.75 to 15 Cc.).

EXTRACTUM NUCIS VOMICÆ.

U. S., Br.

EXTRACT OF NUX VOMICA

(*ex-trăc'tūm nū'cis vōm'icæ*)

"Extract of Nux Vomica, when assayed by the following process, should be found to contain 5 percent. of strychnine." *U. S.*

"An Extract containing 5 per cent. of Strychnine." *Br.*

Extractum Nucum Vomicarum Spirituosum (vel Alcoholicum); Extralt de Nolz Vomique, *Fr. Cod.*; Extractum Strychni, *P. G.*; Weingelstiges Krähenaugenextrakt, Brechnussextrakt, Strychnossamenextrakt, *G.*; Estratto di noce vomica alcoolico, *It.*; Extracto alcoholico de nuez vomica, *Sp.*

* "Nux Vomica, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, Water, Alcohol, Sugar of Milk, dried and in fine powder, each, a *sufficient quantity*. Mix *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Acetic Acid with *thirteen hundred cubic centimeters* [or 43 fluidounces, 460 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then Water, until the percolate passes but faintly imbued with bitterness, and the Nux Vomica is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and, having heated the remainder to boiling, filter, and evaporate the filtrate to a soft extract; dissolve this in the reserved portion, and add enough Water to make the liquid measure *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims]. To the liquid thus obtained, add *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of Alcohol, shake the mixture well, and set it aside for twenty-four hours, with occasional agitation. Filter the liquid through paper, and wash the residue in the filter with a mixture of Alcohol three volumes, and Water one volume, until the washings are only faintly bitter. Evaporate the filtrate and washings in a porcelain dish, on a water-bath, to dryness. Determine, by the method given below, the percentage of strychnine in the dry Extract; ascertain, by calculation, the amount of strychnine in the remainder of the Extract; add to this enough well-dried Sugar of Milk to bring the quantity of strychnine in the final dry Extract of Nux Vomica to 5 percent. of the total weight; and, when thoroughly powdered and mixed, transfer the Extract to small, well-stoppered vials.

Extract of Nux Vomica, when assayed by the following process, should be found to contain 5 percent. of strychnine." *U. S.*

Assay. *U. S.* (8th Rev.)—"Extract of Nux Vomica, *two grammes*; Distilled Water, Ether, Chloroform, Ammonia Water, Sulphuric Acid Solution (3 percent. H_2SO_4), Nitric Acid (sp. gr. 1.40), Sodium Hydroxide Solution (1 in 10), Tenth-normal Sulphuric Acid V.S., Fiftieth-Normal Potassium Hydroxide V.S., Iodo-sin T.S., each, a *sufficient quantity*. Introduce the Extract of Nux Vomica into a beaker, and dissolve it in 25 Cc. of a mixture of 16 Cc. of ether, 5 Cc. of chloroform, and 4 Cc. of ammonia water. When dissolved, transfer it to a separator, rinsing the beaker with a little chloroform and adding the rinsings to the separator. Insert the stopper securely and shake the separator carefully for a few minutes. Draw off the aqueous layer into another separator, washing the ether-solution and separator with a little water, and adding this to the second separator. Then shake out the aqueous liquid with two portions of 15 and 10 Cc., respectively, of chloroform, and add these to the first separator. If a few drops of the liquid left in the second separator still give a reaction with mercuric potassium iodide T.S. after acidulating, repeat the shaking out with 10 Cc. more of chloroform. Now shake out the chloroformic solution in the first separator with three portions of 15, 10, and 10 Cc. of sulphuric acid solution (3 percent.), and collect the combined acid solutions in another separator. Introduce a small piece of red litmus paper, add enough ammonia water to render the liquid alkaline, and extract the mixture with three portions, respectively, of 15, 10, and 10 Cc. of chloroform. Draw off the chloroformic solutions into a beaker, and evaporate the chloroform with the aid of a water-bath. Dissolve the alkaloidal residue in the beaker in 15 Cc. of 3 percent. sulphuric acid solution by the aid of a water-bath, and allow the liquid to cool. To this solution add 3 Cc. of a cooled mixture of equal volumes of nitric acid (specific gravity 1.40) and distilled water, and after rotating the liquid a few times, set it aside for exactly ten minutes, stirring it gently three times during this interval. Transfer the resulting red liquid to a separator containing 25 Cc. of an aqueous solution of sodium hydroxide (1 in 10), and wash the beaker three times with very small amounts of distilled water, and add the washings to the separator. If the liquid is not quite turbid, add 2 Cc. more of the solution of sodium hydroxide. Now add 20 Cc. of chloroform to the separator, and shake it well by a rotating

motion for a few minutes, allow the liquids to separate, and draw off the chloroform through a small filter, wetted with chloroform, into a flask. Repeat this twice, using 10 Cc. of chloroform each time, and draw off both portions into the flask, using the same filter. Finally, wash the filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform by means of a water-bath, very carefully, to avoid decrepitation. To the alkaloidal residue, add 10 Cc. of tenth-normal sulphuric acid V.S., 5 drops of iodeosin T.S., about 90 Cc. of distilled water, and 20 Cc. of ether. When all the alkaloid is dissolved, titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. until the aqueous liquid just turns pink. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 10 (the 10 Cc. of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.0332, and this product by 50, which will give the percentage of strychnine contained in the Extract of Nux Vomica." U. S.

"Liquid Extract of Nux Vomica, 11 fl. ounces (Imperial measure) or 550 cubic centimetres; Milk Sugar, in fine powder, a sufficient quantity. Ascertain the proportion of Milk Sugar required for ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of the Liquid Extract by the following experiment on one fluid ounce (Imp. meas.) or fifty cubic centimetres.

Evaporate one fluid ounce (Imp. meas.) or fifty cubic centimetres of the Liquid Extract of Nux Vomica in a counterpoised dish on a water-bath to a moderately firm extract, and weigh. The difference between the weight of the extract and one hundred and thirty-one and a quarter grains (Imp.) or fifteen grammes, multiplied by ten, will give the amount of Milk Sugar required for the remaining ten ounces (Imp. meas.) or five hundred cubic centimetres of the Liquid Extract of Nux Vomica.

Distil the alcohol from ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of the Liquid Extract of Nux Vomica; to the residue add the quantity of Milk Sugar shown to be required by the above experiment; mix; evaporate to the consistence of a firm extract, which should weigh three ounces (Imp.) or one hundred and fifty grammes." Br.

The process of the Br. Pharm. directs the evaporation of the standardized liquid extract of nux vomica and the addition of sufficient sugar of milk to the residue to make the extract contain 5 per cent. of strychnine. The finished product "has about two-thirds the total alkaloidal strength of the Extract of Nux Vomica of the Br. Pharm. of 1885." Br.

Extract of nux vomica differs from that of the U. S. Pharm. 1890 in its mode of preparation. Acetic acid is the most effective menstruum for nux vomica, but it has the disadvantage of also extracting inert constituents; it leaves the fixed oil in the marc and this is a great point in its favor. The object of concen-

trating the acetous liquid extract, adding alcohol and filtering, is to precipitate the inert constituents.

The U. S. P. (8th Rev.) standard of strength for extract of nux vomica differs from that of the U. S. P. 1890 in that the former requires 5 per cent. of strychnine while the latter demanded 15 per cent. of total alkaloids. The gain has been in the direction of greater definiteness and the adoption of the same standard as that used by the British Pharmacopœia. The assay process is practically that of H. N. Gordin.

If the extract is kept in powder, it is apt to agglutinate into a tough mass. According to Zippel, this may be prevented by adding a little water before the close of the evaporation, and then continuing the evaporation to dryness. Recluz obtained from sixteen ounces of nux vomica the average product of one ounce and a quarter; the yield by the U. S. process should be about 25 per cent. of the weight of the drug used. (See *Proc. A. Ph. A.*, 1894, 551, 643; *P. J.*, 1894, 137.)

Dose, one-fourth to one-half of a grain (0.016 to 0.032 Gm.).

Off. Prep.—Tinctura Nucis Vomicae, U. S.

EXTRACTUM OPII. U. S., Br.

EXTRACT OF OPIUM

(ex-trăc'tum ô-pi-i)

"An Extract containing 20 per cent. of morphine. Br.¹

Extractum Thebæicum; Extrait d'Opium, *Fr. Cod.*; Extrait Thébaïque, *Fr.*; Extractum Opii, *P. G.*; Opiumextrakt, *G.*; Estratto di oppio, *acquoso, It.*; Extracto acuoso de opio, *Sp.*

* "Powdered Opium, one hundred grammes [or 3 ounces av., 231 grains]; Sugar of Milk, recently dried and in fine powder, Water, each, a sufficient quantity. Rub the Powdered Opium, in a mortar, into a smooth paste with two hundred and fifty cubic centimeters [or 8 fluid-ounces, 218 minims] of Water; then transfer to a bottle of the capacity of one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms], wash the mortar with seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of water in successive portions, and add the washings to the contents of the bottle. Cork the bottle, and shake it vigorously once every two hours during twelve hours. Then filter through a rapidly acting, double filter, and pour water on the magma slowly, until the filtrate passes nearly colorless and only faintly bitter.

Concentrate the filtrate and washings in a tared dish, on a water-bath, until the contents weigh about two hundred grammes [or 7 ounces av., 24 grains], and allow the Extract

¹The U. S. P. (8th Rev.) requires extract of opium to contain 20 per cent. of crystallized morphine, while the morphine in the British extract is anhydrous; the latter is therefore about 6 per cent. stronger than the U. S. P. extract.

to become cold. Then weigh it accurately, transfer *twelve grammes* to an Erlenmeyer flask having a capacity of about *one hundred cubic centimeters*, and determine in this portion the amount of morphine by the process of assay given below, using the same quantities of liquids as there directed for *four grammes* of the dry Extract. In another portion of *five grammes* determine the amount of water by drying it in a flat-bottomed dish, at 100° C. (212° F.), until it ceases to lose weight. From the results thus obtained, ascertain by calculation the amount of morphine and of water contained in the remainder of the Extract, add to this enough well-dried Sugar of Milk to bring the quantity of morphine in the final dry Extract to 20 percent., then evaporate the whole to dryness, reduce it to powder, and transfer it to small, well-stoppered vials." U. S.

"Opium, sliced, 1 *pound* (Imperial) or 1000 grammes; Distilled Water, 6 *pints* (Imp. meas.) or 7½ litres. Set aside the sliced Opium with one-third of the Distilled Water for twenty-four hours; express the liquid; thoroughly mix the residue of the Opium with another third of the Distilled Water; set aside for twenty-four hours; express; repeat the operation with the remaining third of the Distilled Water; mix the liquids; strain through flannel; evaporate to about *half a pound* (Imp.) or five hundred grammes.

Test.—Analyzed as described under 'Opium,' using 7 grammes of the Extract in place of the 14 grammes of Opium, this Extract should yield 20 per cent. of morphine. To obtain Extract of Opium of proper strength and consistence, stronger and weaker extracts may be mixed, and stronger extracts may be diluted with Distilled Water or with Milk Sugar as may be necessary." Br.

Assay.—"Extract of Opium, dried at 100° C. (212° F.), *four grammes*; Ammonia Water, *two and two-tenths cubic centimeters*; Alcohol, Ether, Water, Lime Water, each, *a sufficient quantity*. Dissolve the Extract of Opium in 30 Cc. of water, filter the solution through a small filter, and wash the filter and residue with water, until all soluble matters are extracted, collecting the washings separately. Evaporate, in a tared dish, on a water-bath, first, the washings to a small volume, then add the first filtrate, and evaporate the whole to a weight of 10 Gm. Rotate the concentrated solution in the dish, until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 Cc., and rinse the dish with a few drops of water at a time, until the entire solution weighs 15 Gm. Add 7 Gm. (or 8.5 Cc.) of alcohol, shake the flask well, then add 20 Cc. of ether, and repeat the shaking. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during ten minutes, and then set it aside, in a moderately cool place, for at least six hours, or over night.

Remove the stopper carefully, and, should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly acting filters, of a diameter of 7 Cm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ether-solution as completely as possible upon the inner filter. Add 15 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 15 Cc. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when the liquid has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 Cc. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-liquor, and afterwards wash them with alcohol (previously saturated with powdered morphine), added drop by drop from a pipette. When this has passed through, displace the remaining alcohol by ether, using about 10 Cc., or more if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals of morphine to a tared watch-glass and weigh them.

Transfer the crystals (which are not quite pure) to an Erlenmeyer flask, add lime water in the proportion of 10 Cc. for each 0.1 Gm. of morphine, and shake the flask at intervals for twenty-five minutes. Pass the liquid through two counterpoised, rapidly acting, plainly folded filters, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), and rinse the flask with additional lime water, passing the washings through the filter until the filtrate, after acidulation, no longer yields a precipitate with mercuric potassium iodide T.S. Then press the filters between bibulous paper, dry them to a constant weight, and weigh the contents of the inner filter, using the outer as a counterpoise. Subtract the weight of the insoluble matter, on the filter, from the weight of the impure morphine previously found, and the difference, multiplied by 25, will be the percentage of pure crystalline morphine contained in the Extract of Opium." U. S.

The process for the U. S. P. extract differs from that formerly official in several particulars, powdered opium being used instead of opium, and notwithstanding that the powdered opium is standardized, the extract is assayed, and the percentage of morphine adjusted to 20 per cent., so that the extract of opium can now be depended upon to contain slightly more than twice as much morphine as opium of the minimum official strength. The U. S. P. extract is about 1-9th stronger than that of U. S. 1890.

The U. S. P. (8th Rev.) process is a great improvement over those formerly official; in addition to the definite strength of the extract, its reduction to a pulverulent form will enable the pharmacist to dispense it more accurately and conveniently.

As purely aqueous preparations of opium have been found to agree better with certain individuals than opium alone or its alcoholic preparations, there is reason to believe that there are in the crude drug one or more principles, which are capable of causing nausea, headache, nervous disturbances, etc., and which are insoluble in water, though extracted by alcohol or ether. (See *Opium Deodoratum*.)

Dose, one-fourth to one grain (0.016 to 0.065 Gm.).

Off. Prep.—*Extractum Opii Liquidum, Br.*; *Emplastrum Opii, U. S.*

EXTRACTUM OPII LIQUIDUM. Br.

LIQUID EXTRACT OF OPIUM

(ex-trăc'tum ô'pî-i liq'uî-dûm)

"A Liquid Extract containing $\frac{1}{2}$ grain of morphine in 110 minims (0.75 gramme in 100 cubic centimetres)." *Br.*

"Extract of Opium, $\frac{1}{2}$ ounce (Imperial) or 18.75 grammes; Distilled Water, 16 fl. ounces (Imp. meas.) or 400 cubic centimetres; Alcohol (90 per cent.), 4 fl. ounces (Imp. meas.) or 100 cubic centimetres. Mix the Extract of Opium with the Distilled Water; set aside for an hour, stirring frequently; add the Alcohol; set aside in a cool place for twenty-four hours; filter. The product should measure one pint (Imp. meas.) or five hundred cubic centimetres. Specific gravity from 0.985 to 0.995.

Test.—Analyzed as described under '*Tinctura Opii*,' this Liquid Extract should yield an amount of morphine, reckoned as anhydrous, corresponding to not less than 0.7 gramme nor more than 0.8 gramme in 100 cubic centimetres. Each fluid ounce of Liquid Extract of Opium represents $16\frac{1}{2}$ grains of Extract of Opium; 20 cubic centimetres represent 0.75 gramme." *Br.*

In the last revision of the British Pharmacopœia this preparation was reduced in morphine strength 25 per cent.

It is a good preparation, one which has long been needed, and in the absence of which from the Pharmacopœia empirical preparations have obtained a certain vogue. It is well known that in opium there are principles soluble in alcohol but not in water, which often produce various disagreeable effects not experienced from the aqueous extract; what was wanted was a liquid preparation meeting this demand. All that was required was to make an aqueous solution of solid extract, and to add something to preserve it. The British Pharmacopœia uses alcohol for the purpose, and in the original formula employed it in such proportion that an Imperial pint of the liquid should contain three

fluidounces of the spirit, or between one-sixth and one-seventh by measure. But this amount of alcohol, according to Squire, is insufficient for its preservation, and should be doubled. In the present Pharmacopœia the spirit has been increased to four fluidounces, and the water diminished from seventeen to sixteen fluidounces; but even with this increase the spirit constitutes only one-fifth, which is considerably short of the proportion recommended by Squire. A preparation similar to the British was made some years since by Eugene Dupuy of New York. (See *Opium*.) In the *Deodorized Tincture of Opium* of the U. S. Pharmacopœia the advantages of the preparation have, we think, been still better secured.

Dose, five to thirty minims (0.3 to 1.8 Ce.).

EXTRACTUM PHYSOSTIGMATIS.

U. S., Br.

EXTRACT OF PHYSOSTIGMA

(ex-trăc'tum phy-sô-stîg'ma-tîs)

Extract of Calabar Bean; *Extractum Fabæ Calabaricæ*; *Extrait de Fève de Calabar, Fr. Cod.*; *Kalabarbohnenextrakt, Physostigmaextrakt, G.*

* "Physostigma, in No. 80 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Glycyrrhiza, (peeled, Russian), in No. 80 powder, each, a sufficient quantity. Moisten the Physostigma with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until three thousand cubic centimeters [or 101 fluidounces, $3\frac{1}{2}$ fluidrachms] of percolate are obtained, or the Physostigma is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters [or 3 fluidounces, 183 minims]; mix this with the reserved portion, and evaporate, at or below the above-mentioned temperature, on a water-bath, to dryness. Remove one gramme of the Extract, and assay this by the process given below; from the results thus obtained, ascertain by calculation the amount of ether-soluble alkaloids contained in the remainder of the Extract, add to this enough powdered Glycyrrhiza to bring the quantity of the alkaloids in the finished powdered Extract to 2 percent., reduce to powder, mix thoroughly, and transfer it at once to well-stoppered, amber-colored vials. Extract of Physostigma, when assayed by the following process, should be found to contain 2 percent. of ether-soluble alkaloids." *U. S.*

"Calabar Bean, in No. 40 powder, 1 pound (Imperial) or 1000 grammes; Alcohol (90 per cent.), 4 pints (Imp. meas.) or 5 litres; Milk Sugar, in fine powder, a sufficient quantity. Mix the powdered Calabar Bean with one pint (Imp. meas.) or twelve hundred and fifty cubic centimetres of the Alcohol; set aside in a closed vessel for forty-eight hours, agitating occasionally; transfer to a percolator; when the liquid ceases to pass, add the remainder of the Alcohol so that it may slowly percolate through the powder; remove the marc and subject it to pressure; add the expressed liquid to the percolate; filter; recover most of the alcohol by distillation; transfer the residue to a counterpoised basin, and evaporate to the consistence of a very soft extract; weigh; then add three times its weight of Milk Sugar and mix thoroughly to produce a firm Extract. This preparation is one-fourth the strength of the Extract of Calabar Bean of the British Pharmacopœia of 1885." *Br.*

Assay. U. S. P. (8th Rev.).—"Extract of Physostigma, one gramme; Alcohol, Diluted Alcohol, Ether, Sodium Bicarbonate, Normal Sulphuric Acid V.S., Distilled Water, Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Iodeosin T.S., each, a sufficient quantity.

Transfer the Extract of Physostigma to a small porcelain dish, add 5 Cc. of diluted alcohol, and digest for five minutes in a water-bath below boiling temperature; then add about 5 Gm. of very clean, fine quartz sand, and evaporate to dryness on a water-bath, triturating thoroughly with a pestle to secure uniform admixture. When dry, carefully transfer the contents of the dish to an Erlenmeyer flask, add 100 Cc. of ether, and shake the flask. Then add 10 Cc. of an aqueous solution of sodium bicarbonate (1 in 20), and shake the contents vigorously at intervals for one hour. Allow the mixture to stand, and, when settled, decant 50 Cc. of the ether-solution into a separator, to which add a small piece of blue litmus paper, sufficient normal sulphuric acid V.S. to render the liquid acid, and 10 Cc. of distilled water. Shake the separator well for one minute, and draw off the aqueous layer into another separator. Repeat the shaking-out process, using 2 Cc. of normal sulphuric acid V.S. and 8 Cc. of distilled water, and add the acid aqueous layer to the second separator; again repeat the extraction, using 1 Cc. of normal sulphuric acid V.S. and 9 Cc. of distilled water, and add this to the second separator. To the combined acid liquids in the second separator, add 25 Cc. of ether, a small piece of red litmus paper, and sufficient sodium bicarbonate solution (1 in 20) to render it alkaline. Shake the separator for one minute, allow the liquids to separate, and draw off the ether into a beaker. Repeat the shaking-out process with 20 Cc. and again with 15 Cc. of ether added to the separator; shake each time for one minute, allow the liquids to separate, and draw off the ether into the beaker.

Carefully evaporate the ether from the combined solutions by means of a water-bath, and, when dry, dissolve the residue in 2 Cc. of tenth-normal sulphuric acid V.S.; rinse the solution carefully into a 200 Cc. flask with distilled water, add enough distilled water to bring the volume to about 90 Cc., add 25 Cc. of ether, and having shaken the flask, add 5 drops of iodeosin T.S., then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., until, after shaking, the aqueous liquid just acquires a pink color. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 2 (the 2 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0273, and this product by 200; the result will be the percentage of ether-soluble alkaloids contained in the Extract of Physostigma." *U. S.* As alcohol is the best solvent for the active principles of the bean, it is preferred in making the extract, and as it is possible to assay physostigma the U. S. P. (8th Rev.) changed the process so as to make this extract contain a definite proportion of alkaloids by assaying a small portion of the extract made by evaporating the tincture to dryness and from the results thus obtained determining the quantity of powdered glycyrrhiza necessary to make the finished powdered extract contain 2 per cent. of alkaloids.

Dose, from one-twelfth to one-fourth of a grain (0.005 to 0.016 Gm.).

EXTRACTUM QUASSIÆ. U. S.

EXTRACT OF QUASSIA

(ex-trăc'tum quăss'i-æ)

Extrait de quassia amara, *Fr. Cod.*; Extrait de Quassie (Bois amer), *Fr.*; Quassiaextrakt, *G.*; Estratto di quassia acquoso, *It.*

* "Quassia, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Water, Sugar of Milk, recently dried and in fine powder, each, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Moisten the Quassia with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly imbued with bitterness. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then evaporate, by means of a water-bath, to dryness and add enough Sugar of Milk to make the Extract weigh one hundred grammes [or 3 ounces av., 231 grains]. Mix thoroughly, reduce to fine powder, and transfer to well-stoppered bottles." *U. S.*

The British Pharmacopœia (1898) no longer recognizes Extract of Quassia.

A change was made in the process for this extract at the last revision of the U. S. Pharmacopœia. The former extract of pilular consistence was dropped and a powdered extract

adopted, of which 1 grain represents 10 grains of quassia. This extract is scarcely half the strength of the former extract. The pilular aqueous extract of quassia was dark brown or black, and excessively bitter; it was likely to become dry and disposed to crumble by time. It concentrates a greater amount of tonic power within a given weight than any other extract of the simple bitters, and may, therefore, be given with great advantage in cases in which it is desirable to administer this class of substances in as small a bulk as possible.

Dose, from one to two grains (0.065 to 0.13 Gm.).

EXTRACTUM RHAMNI PURSHIANÆ.

U. S. (Br.)

EXTRACT OF CASCARA SAGRADA

(*ex-trăc'tūm rhām'nī pūrsh-i-ā'næ*)

Extractum Cascaræ Sagradæ, Br.: *Extrait de Cascara Sagrada, Fr. Cod.*; *Cascara Sagrada-Extrakt, Amerikanisches Faulbaumrindenextrakt, G.*; *Extracto alcoholico de cascara sagrada, Sp.*

* "Cascara Sagrada, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, Glycyrrhiza (peeled, Russian), in No. 80 powder, each, a sufficient quantity, to make two hundred and fifty grammes [or 8 ounces av., 358 grains]. Mix one hundred and twenty-five cubic centimeters [or 4 fluidounces, 109 minims] of Alcohol with eight hundred and seventy-five cubic centimeters [or 29 fluidounces, 282 minims] of Water, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the drug is exhausted. Reserve the first eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder on a water-bath, at a temperature not exceeding 70° C. (158° F.), to the consistence of syrup. Mix this with the reserved portion, and continue the evaporation, at or below the above-mentioned temperature, to dryness. Reduce the Extract to fine powder, and add enough powdered Glycyrrhiza to make the product weigh two hundred and fifty grammes [or 8 ounces av., 358 grains]. Mix thoroughly." U. S.

"Moisten Cascara Sagrada, in No. 20 powder, with Distilled Water, and let it remain a few hours to soften and swell; then place it loosely in a percolator and percolate with more Distilled Water until it is exhausted. Evaporate

on a water-bath to dryness." Br. This powdered extract was made official in the U. S. P. (8th Rev.) for the first time; 1 part of the extract represents 4 parts of the drug.

The present British preparation (1898) is a dry extract. This preparation well represents the virtues of the bark, and furnishes a good means of administering this purgative in pilular form.

Dose, from two to eight grains (0.13 to 0.5 Gm.).

EXTRACTUM RHEI. U. S., Br.

EXTRACT OF RHUBARB

(*ex-trăc'tūm rhē'i*)

Extractum Rhei Alcoholicum; *Extrait de Rhubarbe, Fr. Cod.*; *Extractum Rhei, P. G.*; *Rhabarberextrakt, G.*; *Estratto di rabarbaro acquoso, It.*; *Extracto acuoso de rubarbo, Sp.*

* "Fluidextract of Rhubarb, one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Evaporate the Fluidextract of Rhubarb in a porcelain dish, by means of a water-bath, with constant stirring, at a temperature not exceeding 50° C. (122° F.), to a pilular consistence." U. S.

"Moisten Rhubarb Root, in No. 20 powder, with Alcohol (60 per cent.), and set aside for forty-eight hours; transfer to a percolator; slowly pass as much of the Alcohol as may be sufficient to exhaust the Rhubarb Root. Remove most of the alcohol by distillation, and evaporate the residual liquid to dryness." Br.

The U. S. P. (8th Rev.) extract is practically identical with that of the former revision, notwithstanding the fact that the present extract is made by evaporating the fluidextract, because the menstruum for exhausting the rhubarb was the same in each case, *i.e.*, 4 volumes of alcohol and 1 volume of water.

The British extract (1898) is now nearly identical with the U. S. preparation; the menstruum used for the former is, however, slightly more aqueous. Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation be performed with great care and with a moderate heat, it is certain that the purgative principle is to a greater or less extent injured or dissipated in the process, and the extract may thus become even less efficient than the root. Among other consequences which result from the boiling temperature is the formation of a compound of the tannin and starch, which is insoluble in cold water, and upon its precipitation probably carries with it a portion of the purgative principle. There is, moreover, reason to believe that this principle is volatilizable by heat, and that a portion of it escapes with the vapor. When properly prepared, the extract has decidedly the peculiar odor of rhubarb.

Dose, from two to ten grains (0.13 to 0.65 Gm.).

EXTRACTUM SCOPOLÆ. U. S.

EXTRACT OF SCOPOLA

(ex-trăc'tum seq-pô'læ)

Extrait de Racine de Scopolia, *Fr.*; Scopolawurzel-extrakt, *G.*

* "Fluidextract of Scopolia, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Evaporate the Fluidextract of Scopolia in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), with constant stirring, to a pilular consistence. When assayed as directed below, Extract of Scopolia should contain 2 percent. of mydriatic alkaloids. If the extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 2 percent." *U. S.*

Assay of Extract of Scopolia. *U. S.* (8th Rev.)—"The method to be employed is identical with that given for Extract of Belladonna Leaves, using *two grammes* of Extract of Scopolia instead of the quantity of Extract of Belladonna Leaves there directed. [See page 470.] The product must be multiplied by 50 instead of 20." *U. S.*

This extract was introduced into the *U. S. Pharmacopœia* (8th Rev.) for the first time. It is largely used by the manufacturers of Belladonna plasters, as it has been shown to contain mydriatic alkaloids equal in therapeutic value to those found in belladonna, and the proportion of the alkaloids is more uniform in the various lots of root in commerce when compared with belladonna root.

Dose, one-eighth to one-fourth of a grain (0.008 to 0.016 Gm.).

EXTRACTUM STRAMONII. U. S., Br.

EXTRACT OF STRAMONIUM

(ex-trăc'tum stră-mō'nī-i)

Extrait de Stramoine (feuille), *Fr. Cod.*; Stechpfeilblätter-extrakt, *G.*

* "Fluidextract of Stramonium, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Evaporate the Fluidextract of Stramonium in a porcelain dish, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), with constant stirring, to a pilular consistence. When assayed as directed below, Extract of Stramonium should contain 1.4 percent. of mydriatic alkaloids. If the Extract should be found by the assay to contain more than this percentage, sufficient powdered sugar of milk should be added to reduce it to the standard of 1.4 percent." *U. S.*

"Pack Stramonium Seeds, in No. 40 powder, in a percolator; exhaust the powder by slow percolation with Alcohol (70 per cent.); remove most of the alcohol from the percolate by distillation; evaporate the residual liquid to the consistence of a firm extract." *Br.*

Assay of Extract of Stramonium. *U. S.* (8th Rev.)—"The method to be employed is identical with that given for Extract of Belladonna Leaves, using *five grammes* of Extract of Stramonium." *U. S.* (See page 470.)

This extract differs from that formerly official, because it is now made by evaporating the fluidextract of stramonium *leaves*; the *U. S. P.* 1890 extract and the British extract are made from the *seed*. The change was made because it was shown that the leaves were as uniform in quality as the seeds and a reliable assay process could be provided which would definitely fix the quality; the fixed oil present in the seeds constitutes an objection to their use. The use of 70 per cent. alcohol by the British Pharmacopœia will probably make a stronger extract by rejecting some of the inert constituents of the seeds soluble in water. According to the table of Recluz, sixteen ounces of the seed afford two ounces and two drachms of extract by maceration in diluted alcohol, and one ounce and a half by decoction.

Dose, from one-sixth to one-fourth of a grain (0.010 to 0.016 Gm.).

Off. Prep.—Unguentum Stramonii, *U. S.*

EXTRACTUM STROPHANTHI. Br.

EXTRACT OF STROPHANTHUS

(ex-trăc'tum strô-phăn'thî)

Extrait de Strophanthus Kombé (Semence), *Fr. Cod.*; Strophanthusextrakt, *G.*

"Strophanthus Seeds, reduced to No. 30 powder, and dried at 110° F. (43.3° C.), 1 ounce (Imperial) or 25 grammes; Purified Ether, Alcohol (90 per cent.), Milk Sugar, of each a *sufficient quantity*. Pack the dried powder in a percolator, and, having moistened it with the Ether, macerate for twenty-four hours; then allow percolation to proceed, continuing the addition of the Ether until the liquid passes through colorless. Remove the marc from the percolator, and dry it, gradually heating it to 120° F. (48.9° C.). Again reduce it to powder, repack in the percolator, and moisten with the Alcohol. Macerate for forty-eight hours, then pour on successive quantities of the Alcohol, percolating slowly, until *half a pint* (Imp. meas.) or two hundred and fifty cubic centimetres of liquid is obtained. Evaporate most of the alcohol; transfer the residual liquid to a counterpoised basin; concentrate until the liquid begins to thicken; then add sufficient finely powdered Milk Sugar to produce *two ounces* (Imp.) or fifty grammes of Extract, in powder." *Br.*

This preparation of the British Pharmacopœia closely resembles an "abstract" of the *U. S. P.* 1880; an important detail, in our opinion, has been neglected in not washing the fatty matter extracted by the ether with diluted alcohol to remove active constituents held by the fatty substances, then evaporating the solu-

tion and incorporating the residue with the extract. The U. S. and Br. processes for the tincture overcome the necessity for the use of ether by employing alcohol containing enough water to leave the fatty substances in the percolator residue, and the same expedient might have proved of value in the process for this preparation.

This extract fills a very decided want of a solid preparation of *strophanthus* that can be administered in pill and capsule, and is without doubt efficient. A grain of it may be considered to represent five minims of the U. S. (8th Rev.) tincture of *strophanthus*.

Dose, as given in the British Pharmacopœia, from one-fourth to one grain (0.016 to 0.065 Gm.).

EXTRACTUM SUMBUL. U. S.

EXTRACT OF SUMBUL

(*ex-trăc'tūm sūm'bŭl*)

Extract of Muskroot; *Extrait de Racine de Sumbul*, Fr.; *Sumbulwurzelextrakt*, *Moschuswurzelextrakt*, G.

* "Fluidextract of Sumbul, one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Evaporate the Fluidextract of Sumbul in a porcelain dish, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), with constant stirring, to a pilular consistence." U. S. This is a new official extract, intended to furnish a convenient method of administering *sumbul* in the form of pills or capsules.

Dose, two to five grains (0.13 to 0.32 Gm.).

EXTRACTUM TARAXACI. U. S., Br.

EXTRACT OF TARAXACUM

(*ex-trăc'tūm tă-răx'ă-ci*)

Extract of Dandelion; *Extrait de Dent-de-lion*, Fr.; *Löwenzahnextrakt*, G.; *Estratto di tarassaco acquoso*, It.

* "Taraxacum, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity. Mix one hundred and twenty-five cubic centimeters [or 4 fluidounces, 109 minims] of Alcohol with eight hundred and seventy-five cubic centimeters [or 29 fluidounces, 282 minims] of Water, and, having moistened the powder with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of the mixture, pack it in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Taraxacum is exhausted. Evaporate the percolate, by means of a water-bath, to a pilular consistence." U. S.

"Crush fresh Taraxacum Root; press out the juice; allow the feculence to subside; heat the

liquid to 212° F. (100° C.), and maintain the temperature for ten minutes; strain; evaporate to the consistence of a soft extract." Br.

The inspissated taraxacum juice of the former U. S. Pharmacopœias has been superseded by the present hydro-alcoholic extract, because of the very variable quality of the former; if the root is of good quality a better extract can be made by percolation and evaporation in the usual way.

The extract made from the juice is undoubtedly stronger when prepared from the root alone than from the whole plant. It is important that the root should be collected at the right season. The juice expressed from it in the spring is thin, watery, and of a feeble flavor; in the latter part of the summer, and in autumn, thick, opaque, cream-colored, very bitter, and abundant, amounting to one-third or one-half its weight. It may be collected in August, and afterwards until severe frost. According to Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the root. An extract prepared by inspissating the juice is more efficient than that prepared in the old way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure during evaporation changes the bitterness of the juice into sweetness, which is a sign of inferiority. In the British process it is wisely directed that before the evaporation of the juice it shall be exposed for a short time to a heat sufficient to coagulate the albumen, which is then separated and rejected as useless; it is indeed injurious, by favoring decomposition. As often found in the shops, the extract is dark-colored, sweet, and in all probability nearly inert. Houlton took more than an ounce of it in a day, without any sensible effect. (*P. J.*, i. 421.) When prepared from the root and leaves together, it has a greenish color. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained from plants collected in November, and the least in April and May. This extract deteriorates by keeping. It is conveniently given in an aromatic water.

Dose, from fifteen grains to a drachm (1 to 3.9 Gm.) three times a day.

FEL BOVIS. U. S.

OXGALL

(*fēl bō'vīs*)

"The fresh bile of *Bos taurus* Linné." U. S.

Fel Bovinum, Fel Tauri, Bile Bubula, Ox Bile; Bile de Bœuf, Fr. *Od.*; Ochsehgalle, Rindsgalle, G.; Hiel de toro, Sp.

contents with a little more Alcohol (90 per cent.). Distil off most of the Alcohol from the mixed liquids, and evaporate the residue in a porcelain dish, by the heat of a water-bath, until it acquires the consistence of a thick extract." *Br.*

The object of this preparation is to furnish purified concentrated Oxgall in a condition in which it can be satisfactorily prescribed for internal administration. The addition of alcohol to the concentrated liquid is made for the purpose of separating albuminous matter.

Properties.—The U. S. Pharmacopœia describes Purified Oxgall, and requires it to respond to the following tests: "A yellowish-green, soft solid, having a peculiar odor, and a partly sweet and partly bitter taste. Very soluble in water and in alcohol: A solution of 1 part of Purified Oxgall in about 100 parts of water behaves toward sugar and sulphuric acid in the same manner as the solution mentioned under *Fel Bovis*. An aqueous solution of Purified Oxgall should be clear, and should remain transparent upon the addition of an equal volume of alcohol (evidence of proper purification)." *U. S.* "A yellowish-green hygroscopic substance, having a taste partly sweet and partly bitter, soluble in water and in alcohol (90 per cent.). A solution in twenty or thirty times its weight of water, when treated, first with a drop of freshly made syrup consisting of one part of Refined Sugar and four of water, and then with sulphuric acid cautiously added until the precipitate at first formed is redissolved, gradually acquires a cherry-red color, which changes in succession to carmine, purple, and violet. Its aqueous solution gives no precipitate on the addition of alcohol (90 per cent.) (absence of unpurified ox bile)." *Br.*

Refined oxgall, much used by painters, is prepared, according to Gray, in the following manner. Take of "fresh oxgall, one pint; boil, skim, and add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months; then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colorless."

Uses.—Bile was formerly highly valued as a remedy in numerous complaints, and was considered peculiarly applicable to cases attended with deficient biliary secretion. Its use has, however, passed out of vogue, probably with insufficient reason, as it has been proven that the bile salts are the most powerful stimulants to the secretory activity of the liver known. We have employed it in large doses in *catarrhal jaundice* with apparently excellent results. Also, at our suggestion it has been used as a local application to sinuses and foul sores in horses, with favorable reports; recent researches show that the bile of venomous snakes, and

probably to a less extent the bile of other animals, is antidotal to snake venom. (See *Snake Venom*, PART II.)

Dose, five to twenty grains (0.32 to 1.30 Gm.).

FERRI ARSENAS. *Br.*

IRON ARSENATE [Arseniate of Iron, *Br.* 1885]

(fĕr'ī ār'se-nās)

"Ferrous arsenate, $\text{Fe}(\text{AsO}_4)_2 \cdot 6\text{H}_2\text{O}$, with ferric arsenate and some iron oxide." *Br.*

Ferrum Arsenicum; Ferrous Arsenate; Arséniate Ferreux, *Fr. Cod.*; Arséniate de Fer, *Fr.*; Arsensaures Eisen, *Arsensaures Eisenoxydul*, *G.*; Arseniato ferro-ferrico, *It.*; Arseniato de hierro, *Sp.*

"Ferrous Sulphate, 20½ ounces (Imperial) or 415 grammes; Sodium Arsenate, dried, 26½ ounces (Imp.) or 530 grammes; Sodium Bicarbonate, 4½ ounces (Imp.) or 90 grammes; Distilled Water, boiling, a sufficient quantity. Dissolve the Sodium Arsenate in about five pints (Imp. meas.) or two litres, and the Ferrous Sulphate in about six pints (Imp. meas.) or two thousand four hundred cubic centimetres of the Distilled Water; mix the solutions; add the Sodium Bicarbonate dissolved in a little cold Distilled Water; stir thoroughly; collect the resulting precipitate on a calico filter; wash until free from sulphates; squeeze the washed precipitate between folds of strong linen in a screw-press; dry it on porous bricks in a warm air-chamber, the temperature of which does not exceed 100° F. (37.8° C.)." *Br.*

This is an official salt of the British Pharmacopœia. The washed precipitate, described in the process is ferrous arsenate (FeAs_2O_6). A portion of ferrous arsenate remains dissolved in the solution. This is precipitated by the sodium bicarbonate, which also neutralizes the sulphuric acid liberated during the reaction, and carbon dioxide is evolved, thus:

Ferrous arsenate is white when first formed, but quickly turns green on exposure to the air during the process of washing and drying, and finally becomes a ferroso-ferric arsenate of the probable composition $3\text{Fe}(\text{FeO})\text{AsO}_4 \cdot 16\text{H}_2\text{O}$. It is an amorphous powder, without odor or taste, insoluble in water, but readily dissolved by hydrochloric acid. The British Pharmacopœia gives the following characters of the salt: "A tasteless amorphous powder of a greenish color, insoluble in water, but readily dissolved by hydrochloric acid. It affords the reactions characteristic of ferrous and ferric salts and of arsenates. Each gramme dissolved in an excess of sulphuric acid diluted with water should not cease to give a blue precipitate with solution of potassium ferricyanide until at least 6.7 cubic centimetres of the volumetric solution of potassium bichromate have been added, corresponding to nearly 12½ per cent. of hydrous,

or 10 per cent. of anhydrous, ferrous arsenate. It should yield no characteristic reaction with the tests for sulphates." The quantitative test proves that there is a due proportion of ferrous oxide present; for the potassium dichromate oxidizes the ferrous oxide, and until this is wholly converted into ferric oxide a blue precipitate continues to be produced, ceasing, however, when the conversion is complete. Thomas S. Barrie (*C. D.*, 1900, 484) found that iron arsenate is of variable composition and that the percentage of ferrous oxide affords no reliable indication of the amount of arsenic anhydride in the dried iron arsenate. For Nicholl's method of estimating the quantity of arsenic in iron arsenate see *Y. B. P.*, 1903, 572, 577.

Uses.—Ferrous arsenate is said to unite the virtues of the two metals which enter into its composition, but the quantity of iron in any permissible dose is so small as to be nearly or quite insignificant, and the activity of the medicine is in fact due to the arsenic alone. The complaints in which it has been found efficient are those in which arsenic in other forms has proved to be a most valuable remedy, and, judging from our own observation, there is no one of them in which the common solution of potassium arsenite will not produce all the effects that can be obtained from the arsenical preparations, with which this ought undoubtedly to be ranked rather than with the chalybeates. Should the coexistence of an anæmic state of the system with any disease requiring the use of arsenic indicate the joint use of iron, it would be unsafe to depend on ferrous arsenate alone. This remedy is peculiarly useful in chronic affections of the skin, especially those of a scaly character, as *lepra*, *psoriasis*, and the advanced stage of *eczema* and *impetigo*. It is useful also in *lupus*, and, mixed with twelve times its weight of simple cerate, may be employed externally in *cancerous ulcers*, though much caution is requisite.

Dose, from one-tenth to one-eighth of a grain (0.006 to 0.008 Gm.), of which about one-half is ferrous oxide.

FERRI CARBONAS SACCHARATUS.

U. S., Br.

SACCHARATED FERROUS CARBONATE

(fēr'ri cār'bō-nās sāk-çhā-rā'tūs)

"Saccharated Ferrous Carbonate should contain not less than 15 percent. of Ferrous Carbonate [$\text{FeCO}_3 = 115.05$], and should be kept in small, well-stoppered bottles." *U. S.* "Ferrous oxycarbonate, $x\text{FeCO}_3, y\text{Fe}(\text{OH})_2$, more or less oxidized, mixed with sugar; the ferrous salt, if reckoned as carbonate, FeCO_3 , forming about one-third of the mixture." *Br.*

Saccharated Iron Carbonate; Saccharated Carbonate of Iron; Carbonas Ferrosus Saccharatus; Saccharure de Carbonate Ferreux, *Fr.*; Ferrum Carbonicum Saccharatum, *P. G.*; Zuckerhaltiges Kohlen-saures Eisen, Zuckerhaltiges Ferrocarbonat, *G.*

* "Ferrous Sulphate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Bicarbonate, *thirty-five grammes* [or 1 ounce av., 103 grains]; Sugar, in fine powder, Distilled Water, each, a *sufficient quantity*, to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Ferrous Sulphate in *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of hot Distilled Water, and the Sodium Bicarbonate in *five hundred cubic centimeters* [or about 17 fluidounces] of Distilled Water at a temperature not exceeding 50°C. (122°F.), and filter the solutions separately. To the solution of Sodium Bicarbonate contained in a flask having a capacity of about *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] add, gradually, the solution of Ferrous Sulphate, and mix thoroughly by rotating the flask. Fill the flask with boiling Distilled Water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, and then fill the flask again with hot Distilled Water, and shake it. Again draw off the clear liquid, and repeat the washing with hot Distilled Water in the same manner until the decanted liquid gives merely a slight cloudiness with barium chloride T.S. Finally drain the precipitate thoroughly on a muslin strainer, transfer it to a porcelain dish containing *eighty grammes* [or 2 ounces av., 360 grains] of Sugar, and mix it intimately. Evaporate the mixture to dryness, by means of a water-bath, reduce it to powder, and mix intimately with it, if necessary, enough well-dried Sugar to make the final product weigh *one hundred grammes* [or 3 ounces av., 231 grains]." *U. S.*

"Ferrous Sulphate, *2 ounces* (Imperial) or 40 grammes; Ammonium Carbonate, *1½ ounces* (Imp.) or 25 grammes; Distilled Water, boiling, *2 gallons* (Imp. meas.) or 6400 cubic centimetres; Refined Sugar, *1 ounce* (Imp.) or 20 grammes. Dissolve the Ferrous Sulphate and the Ammonium Carbonate each in one-quarter of the Distilled Water; add the former to the latter with brisk stirring, in a deep cylindrical vessel; cover this so as to protect it as much as possible from the air; set the mixture aside for twenty-four hours; separate the supernatant liquid from the precipitate by means of a siphon; pour on the remainder of the Distilled Water; stir well; after subsidence remove the clear liquid; collect the precipitate on a calico filter; subject it to expression; triturate it with the Refined Sugar in a porcelain mortar; dry the mixture at a temperature not exceeding 212°F. (100°C.)." *Br.*

This was introduced into the U. S. P. in 1880; the process is identical with that of the former German Pharmacopœia. When solutions of ferrous sulphate and sodium carbonate are mixed together, there are formed, by double decomposition, sodium sulphate which remains in solution, and ferrous carbonate which falls as a pale-blue precipitate. This precipitate begins immediately to alter in nature by the ab-

sorption of oxygen, and, if washed and dried in the ordinary way, becomes ferric oxide, associated with a small quantity of the ferrous carbonate, which has escaped change. As the preparations of iron containing ferrous oxide are the most esteemed, the change which this precipitate undergoes has always been a matter of regret, and various attempts have been made to prevent it. Saccharine matter has been ascertained to possess the required preservative properties, and in the preparation under consideration it is used to prevent the ferrous carbonate as first precipitated from passing into the ferric hydroxide.

Becker, a German physician, was the first to suggest the use of saccharine matter as a means of protection against the absorption of oxygen, and the idea was carried out by Klauer, a German chemist, who first made the saccharated ferrous carbonate. The use of boiling distilled water in the process is to avoid the action of the air contained in unboiled water. The washed precipitate is pressed so as to free it from water as far as possible, and then incorporated with the sugar in fine powder. The mode of treating the precipitate unnecessarily exposes it to the action of the air, and the late London method of incorporating it with the sugar immediately after washing was on this account preferable. The final drying temperature should not exceed 54.5° C. (130° F.).¹ (See *A. Pharm.*, Jan. 1878; *N. R.*, 1878, 1881.)

Properties.—"A greenish-brown powder, gradually becoming oxidized by contact with air, without odor, and having at first a sweetish, afterwards a slightly ferruginous taste. Only partially soluble in water, but completely soluble upon the addition of hydrochloric acid, with copious evolution of carbon dioxide, forming a clear, greenish-yellow liquid. If 1 Gm. of Saccharated Ferrous Carbonate be dissolved in 5 Cc. of hydrochloric acid, and the solution diluted with water until it measures 50 Cc., portions of this solution will yield a blue precipitate with both potassium ferrocyanide T.S. and potassium ferricyanide T.S., but should not

give more than a slight cloudiness with barium chloride T.S. (absence of sulphate). If 1.15 Gm. of Saccharated Ferrous Carbonate be dissolved in 10 Cc. of diluted sulphuric acid, and the solution diluted with water to about 100 Cc., it should require not less than 15 Cc. of tenth-normal potassium permanganate V.S. to impart a permanent pink tint to the liquid, corresponding to not less than 15 percent. of ferrous carbonate." *U. S.*

Saccharated ferrous carbonate is frequently seen in small coherent lumps, usually of a grayish-brown color, permanent in the air, having a sweet, styptic taste, and wholly and readily soluble in warm hydrochloric acid, diluted with half its volume of water, with effervescence. According to the last revision of the British Pharmacopœia, it is described as being in "small coherent lumps or powder, of a brownish-gray color with a sweet, feebly chalybeate taste. It dissolves with effervescence in warm hydrochloric acid diluted with half its volume of water. Each gramme, dissolved in excess of warm Concentrated Phosphoric Acid and diluted with water, should not cease to give a blue precipitate with solution of potassium ferricyanide until at least 29 cubic centimetres of the volumetric solution of potassium bichromate have been added. It should yield only the slightest characteristic reactions with the tests for sulphates." The presence of ferric oxide is a defect, which is avoided in Vallet's ferruginous mass.

Its solution in diluted hydrochloric acid is but slightly affected by potassium ferrocyanide, showing the presence of the ferric salt in only small proportion, but yields a copious blue precipitate with the ferricyanide, proving the abundance of the ferrous compound. The same solution should give but a very slight precipitate with barium chloride, evincing that very little either of ferrous or of sodium sulphate has escaped the washing process. The quantitative tests determine the quantity of ferrous salt present, requiring in the British test the stated amount of the potassium bichromate to convert it into the ferric chloride, and of potassium permanganate in the test of the *U. S. Pharmacopœia*.

Uses.—This preparation is an excellent chalybeate, possessing the advantages of having nearly all the iron in it in the ferrous state, and of being readily soluble in acids. Originally introduced into the official list by the Edinburgh College, it appeared for the first time in the Dublin and London Pharmacopœias of 1850 and 1851. It is undoubtedly more active than the ferric subcarbonate, and must be used in a smaller dose. It is, however, inferior to Vallet's ferruginous mass, in the preparation of which the anti-oxidizing influence of saccharine matter is much more fully applied.

Dose, of the saccharated ferrous carbonate, from five to thirty grains (0.32 to 2.0 Gm.), given in the form of pill.

¹ *Saccharated Ferric Oxide. Saccharum Ferrugineum.*—This is a combination of sugar and ferric oxide. It is soluble and of a pure sweet taste. According to the method of Siebert, to prepare it dissolve two parts of iron in twenty-four parts of nitric acid, sp. gr. 1.2; evaporate the filtrate to fifteen parts; when quite cool, dissolve twelve parts of sugar in the filtrate, and add an excess of a solution of twelve parts of sugar in twelve parts of 20 per cent. ammonia water. After setting aside for twenty-four hours, precipitate this with four or five times its volume of strong alcohol; collect the precipitate, partially dry with bibulous paper, intimately mix the moist mass with its own weight of powdered sugar, and dry by a moderate heat. It is a good antidote for arsenic. (*A. J. P.*, xl. 324, 326. See also *Neues Repertor. für Pharm.*, xviii. 36.) Keutmann (*Int. Pharm. Gen. Anz.*, 1893, 214) dissolves ferrous sulphate in water, precipitates the solution (placed in a bottle) with ammonia water, fills the bottle with water, decants, washing the precipitate repeatedly with hot water; the precipitate is placed in a porcelain dish containing pulverized sugar warmed, a small quantity of alkali added, and hydrogen peroxide added to complete the oxidation; the mixture is then dried.

FERRI CHLORIDUM. U. S.

FERRIC CHLORIDE [Iron Perchloride]

(fēr'i chlō'rj-dūm)

"Ferrie Chloride should contain not less than 22 percent. of metallic iron in the form of chloride." U. S.

Sesquichloride (Perchloride) of Iron, Chloride of Iron; Ferrum Muraticum Oxydatum, Chloridum vel Chloruretum Ferricum, Ferri Perchloridum, Chlorure ferrique, *Fr. Cod.*; Perchlorure de Fer, *Fr.*; Ferrum sesquichloratum, *P. G.*; Eisenchlorid, *G.*; Cloruro ferrico, *Sp.*

* "Solution of Ferrie Chloride, one hundred grammes [or 3 ounces av., 231 grains], to make forty grammes [or 1 ounce av., 180 grains]. Evaporate the Solution of Ferrie Chloride on a water-bath until it weighs forty grammes [or 1 ounce av., 180 grains]; then set it aside in a glass-covered vessel, until it forms a crystalline mass. Lastly, break the salt into pieces, and keep it in glass-stoppered bottles, protected from light." U. S.

The U. S. P. (8th Rev.) does not give a process for making this salt directly from metallic iron, but simply evaporates the official solution of ferrie chloride. The former U. S. P. directed a process which had been adopted with but little alteration from that of Wittstein. (*Prac. Pharm. Chem.*, Darby's transl., p. 265.) When iron is heated with hydrochloric acid, water is decomposed, the hydrogen escapes with effervescence, and the oxygen uniting with the iron forms ferrous oxide, which reacts with the hydrochloric acid to form water and ferrous chloride.¹ The next step of the process is to convert the ferrous chloride into the ferrie salt. This is effected by treating it with hydrochloric and nitric acids and heating until red fumes no longer escape. The following reaction explains this:

The solution is then evaporated, and, on cooling, concretes into a crystalline mass. The relative proportions of iron and the two acids are adjusted very nearly to the production of these results. There are two crystallized chlorides, one, $\text{FeCl}_3 + 3\text{H}_2\text{O}$, which is very deliquescent, the other, $\text{FeCl}_3 + 6\text{H}_2\text{O}$, which is less so, but which, when allowed to stand over sulphuric acid, liquefies and slowly deposits crystals of the first chloride, $\text{FeCl}_3 + 3\text{H}_2\text{O}$, losing half of its water of hydration.²

¹ The Paris Pharmaceutical Society have adopted the following preparations of ferrous chloride, made by dissolving iron in hydrochloric acid and evaporating the filtered solution rapidly to dryness.

Syrup of Ferrous Chloride.—Dissolve 5 grammes of dry ferrous chloride in 20 grammes of orange-flower water, and add 800 grammes syrup of gum and 175 grammes syrup of orange-flower.

Pills of Ferrous Chloride.—Dry ferrous chloride, powdered marshmallow-root, each 10 grammes, mucilage sufficient. Make into 100 pills, which are to be silvered.

² *Syrupus Ferri Chloridi* (Edel). *Syrup of Iron Chloride.*—Take of Solution of Chloride of Iron (U. S. P.), 208 minims; Potassium Citrate, 224 grains; Citric Acid, 60 grains; Water, 8 fluidounces; Glycerin, 5 fluidounces; Syrup, 16 fluidounces. Dis-

The requirement of the U. S. P. (8th Rev.) that ferrie chloride should contain not less than 22 per cent. of metallic iron, is low. If the solution from which it is made contains not less than 10 per cent. of iron, as is required, the salt should theoretically contain not less than 25 per cent. of iron; but on account of the avidity with which it absorbs moisture an allowance on this account is proper.

Properties.—It is in "orange-yellow, crystalline pieces, odorless, or having a faint odor of hydrochloric acid, and a strongly styptic taste. Very deliquescent in moist air. Freely and completely soluble in water and in alcohol; also in a mixture of 1 part of ether and 3 parts of alcohol. At 35.5° C. (96° F.) the salt fuses to a reddish-brown liquid. When strongly heated, it decomposes, losing water and hydrochloric acid, while the anhydrous salt sublimes, leaving a residue of ferrie oxide. The dilute, aqueous solution of the salt shows an acid reaction with blue litmus paper, yields a brownish-red precipitate with ammonia water, a blue precipitate with potassium ferrocyanide T.S., and a white precipitate, insoluble in nitric acid, with silver nitrate T.S. If 1 Gm. of the salt, dissolved in 25 Cc. of boiling water, be treated with an excess of ammonia water, the filtrate should be colorless, and, after acidulation with hydrochloric acid, 20 Cc. of the solution should not respond to the Time-Limit Test for *heavy metals* (see PART III). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and an aqueous solution of the salt (1 in 10), the crystal should not become brown in color, nor should a brownish-black color be developed around it within five minutes (limit of *nitric acid*). If to a solution of the salt (1 in 50) a few drops of freshly prepared potassium ferriocyanide T.S. be added, a pure brown color should be produced, which should not turn at once to a green or greenish-blue (absence of *ferrous salt*). If 1 Gm. of dry Ferrie Chloride be dissolved in sufficient water to measure 100 Cc., then 55.5 Cc. of this solution, when measured into a glass-stoppered flask of the capacity of about 250 Cc., followed by 3 Cc. of hydrochloric acid, and 2 Gm. of potassium iodide, should, after securely stoppering the flask and heating for half an hour at 40° C. (104° F.), and cooling, require not less than 22 Cc. of tenth-normal sodium thiosulphate

to solve the potassium citrate and citric acid in the water, add the iron solution, and when the reaction ceases filter the solution, then add the glycerin and syrup. (*D. C.*, 1894, 246.)

Tasteless Iron Chloride is made by adding an alkaline citrate in solution to a solution of iron sesquichloride, in such proportion that there shall be two molecules of the former to three molecules of chlorine. Usually from 120 to 140 grains of citric acid saturated with soda, potassa, or ammonia are required for the preparation of an ounce of a tincture of corresponding strength to the official tincture. The addition should be made to the liquor, and the final solution must not contain more than 40 per cent. of alcohol. R. Rother affirms that these so-called salts are mere mixtures of iron citrate and iodide or chloride of the alkali used. (*A. J. P.*, 1876, p. 171.)

V.S. for complete decolorization (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." U. S. It contains a variable proportion of water according to the crystalline forms it is made to assume, having about 40 per cent., or six molecules, when in fine acicular crystals, and only 22 per cent., or two and a half molecules, when in the form of larger tables.

Uses.—Ferric chloride is used almost exclusively in the form of tincture or liquor, and in reference to its effect and application we refer to *Tinctura Ferri Chloridi* and *Liquor Ferri Chloridi*. Excepting deliquescence, it keeps without change. When used, it may be dissolved in water in such proportions as may be required. Six, three, two, and one and a half drachms to a fluidounce of water have been recommended, the stronger solutions being used in the treatment of *varices*, the weaker for injection into *aneurisms*, and for application to *bleeding surfaces*, etc. J. Z. Lawrence of England, has used it as a styptic in a semi-deliquescent state and found it extremely efficient. He keeps it in a bottle, in which it gradually deliquesces, and while it is in this condition he applies the thick liquid portion, by means of a brush of spun glass, to the bleeding surface.

FERRI CITRAS. U. S.

FERRIC CITRATE

(fēr'ī cī'trās)

"It should contain Ferric Citrate corresponding in amount to not less than 16 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light." U. S.

Citrate of Iron; Citras Ferricus; Citrate de Sesquioxide de Fer, Citrate ferrique, *Fr.*; Ferrum Citricum Oxydatum, *P. G.*; Ferricitrat, Citronensaures Eisenoxyd, *Elsencitrat*, *G.*; Citrato di ferro, *It.*; Citrato ferrico, *Sp.*

No process is given in the U. S. P. (8th Rev.) for ferric citrate. The process of the U. S. P. 1890 and that for the solution of ferric citrate are appended.¹

¹ "Solution of Ferric Citrate, a convenient quantity. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

Liquor Ferri Citratis, U. S. 1890. *Solution of Ferric Citrate.*—"An aqueous solution of Ferric Citrate, corresponding to about 7.5 per cent. of metallic iron." U. S. 1890.

"Solution of Ferric Sulphate, one thousand and fifty grammes [or 37 ounces av., 16 grains]; Citric Acid, three hundred grammes [or 10 ounces av., 255 grains]; Ammonia Water, eight hundred and eighty cubic centimeters [or 29 fluidounces, 363 minims]; Water, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Mix the Ammonia Water with three thousand cubic centimeters [or 101 fluidounces, 213 minims] of cold Water, and the Solution of Ferric Sulphate with ten thousand cubic centimeters [or 338 fluidounces, 70 minims] of cold Water. Add the latter solution slowly to the diluted Ammonia Water, with constant

stirring. Pour the mixture on a wet muslin strainer, and allow the liquid to run off and the precipitate to drain. Then remove the moist mass from the strainer, mix it well with six thousand cubic centimeters [or 202 fluidounces, 426 minims] of cold Water, again pour it on the strainer, and let it drain. Repeat this washing with several successive portions of cold Water in the same manner, until the washings cease to produce more than a slight cloudiness with barium chloride test-solution. Then allow the precipitate to drain completely, transfer it to a porcelain capsule, add the Citric Acid, and heat the mixture on a water-bath, to 60° C. (140° F.), stirring constantly, until the precipitate is dissolved. Lastly, filter the liquid, and evaporate it, at the above-mentioned temperature, until it weighs one thousand grammes [or 35 ounces av., 120 grains]." U. S. 1890.

In this process, the ferric hydroxide is first obtained by treating solution of ferric sulphate with ammonia, and is then combined, by the aid of heat, with the citric acid, thus forming a solution of ferric citrate. It might appear, from the phraseology of the process, that in the direction to add the citric acid to the precipitated hydroxide, the addition of water to hold the resulting citrate in solution had been omitted; but the precipitate, even after draining, retains mechanically quite sufficient water for the purpose, so much, indeed, that evaporation is necessary at the end of the process to reduce the bulk to the required standard. The temperature is limited to 60° C. (140° F.), because, though a moderate heat promotes the solution, a high degree of it diminishes the solubility of the oxide, and thus interferes with the process.

The solution is "a dark brown liquid, odorless, and possessing a slightly ferruginous taste. Specific gravity, about 1.250 at 15° C. (59° F.). Upon evaporating 100 Gm. of the Solution, in a thin layer, on plates of glass, about 42.5 to 43 Gm. of garnet-red scales will be obtained. The Solution has an acid reaction upon litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide test-solution it affords a bluish-green color or precipitate, which is increased and rendered dark blue by the subsequent addition of hydrochloric acid. On heating the Solution with potassium or sodium hydrate test-solution, it will yield a brown precipitate, without evolving vapor of ammonia. If a portion of the Solution, diluted with 4 volumes of water, be deprived of its iron by boiling it with an excess of potassium or sodium hydrate test-solution, and the filtrate slightly acidulated with acetic acid, a portion of this liquid, when allowed to stand for some time, should not give a white, crystalline precipitate (absence of *tartrate*). If to another portion of the acidulated and cooled filtrate a little calcium chloride test-solution be added, and the liquid heated to boiling, it should gradually deposit a white, crystalline precipitate. If 1.12 (1.1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 15 Cc. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each Cc. of the volumetric solution indicating 0.5 per cent. of metallic iron)." U. S. 1890. It keeps for a long time without change, and answers admirably well for preparing solid ferric citrate and the chalybeate salts containing it, and for introducing it into extemporaneous mixtures. Each fluidounce of it contains about half a troyounce of ferric citrate. It may be given as a ferruginous tonic, in the dose of ten minims (0.6 Cc.), equivalent to five grains (0.32 Gm.) of the salt, several times a day.

be thoroughly washed to free it from sulphates, otherwise brilliant scales will not be formed. (See process in footnote.)

Properties.—Ferric citrate is in "thin, transparent, garnet-red scales, without odor, and having a slightly ferruginous taste. Slowly but completely soluble in water at 25° C. (77° F.), and readily soluble in hot water, but diminishing in solubility with age; insoluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper (absence of *citrates* or *tartrates* of the *alkali metals*). An aqueous solution of the salt shows an acid reaction with blue litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. the aqueous solution yields a bluish-green color or precipitate, which is increased and rendered dark blue by the subsequent addition of hydrochloric acid (difference from *iron and ammonium citrate*). If Ferric Citrate be heated with potassium hydroxide T.S., it yields a brownish-red precipitate, without evolving ammonia. If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually afford a white crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for twenty-four hours, should not deposit a white crystalline precipitate (absence of *tartrate*). If 0.555 Gm. of Ferric Citrate be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., with the aid of a gentle heat, and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 16 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." U. S.

Uses.—Ferric citrate was introduced to the notice of the profession, in 1831, by Béral of Paris. It is a pleasant chalybeate, and is best given in solution.

Dose, of the salt, from three to ten grains (0.2 to 0.65 Gm.).

FERRI ET AMMONII CITRAS.

U. S., Br.

IRON AND AMMONIUM CITRATE [Ammonio-Ferric Citrate, Soluble Ferric Citrate]

(fēr'ri ēt am-mō'nī-i cī'trās)

"It should contain Iron and Ammonium Citrate corresponding in amount to not less

than 16 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light." U. S.

Citrate of Iron and Ammonia; Ferri et Ammonie Citras, Br. 1867; Ferrum Citricum Ammoniatum, Ferri Ammonio-Citras, Ferro-Ammonium Citricum; Ammonio-Citrate of Iron, Soluble Citrate of Iron; Citrate de Fer et d'Ammoniaque (de Fer ammoniacal), Fr. Cod.; Citrate Ferrique Ammoniacal, Fr.; Citronensäures Eisenoxyd-Ammonium (Ammoniak), Ferriammoniumcitrat, G.; Citrato ferrico-ammonico, Sp.

The U. S. P. 1890 process was as follows: "Solution of Ferric Citrate, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Ammonia Water, *forty cubic centimeters* [or 1 fluidounce, 169 minims]. Mix the solution of Ferric Citrate with the Ammonia Water, evaporate the mixture, by means of a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

"Solution of Ferric Sulphate, 10 fl. ounces (Imperial measure) or a sufficient quantity, or 200 cubic centimetres or a sufficient quantity; Solution of Ammonia, 23 fl. ounces (Imp. meas.) or a sufficient quantity, or 460 cubic centimetres or a sufficient quantity; Citric Acid, 4 ounces (Imp.) or 80 grammes; Distilled Water, a sufficient quantity. Prepare ferric hydroxide as follows: Mix sixteen fluid ounces (Imp. meas.) or three hundred and twenty cubic centimetres of the Solution of Ammonia with two pints (Imp. meas.) or eight hundred cubic centimetres of Distilled Water; gradually add to this the Solution of Ferric Sulphate, previously diluted with two pints (Imp. meas.) or eight hundred cubic centimetres of Distilled Water; stir constantly and briskly, taking care that ammonia is, finally, in slight excess as indicated by the odor; set aside the mixture for two hours, stirring it occasionally; pour it on a calico filter; when the liquid has drained away, wash the precipitated ferric hydroxide with Distilled Water until free from sulphates.

Dissolve the Citric Acid in its own weight of Distilled Water; warm the mixture on a water-bath; add the ferric hydroxide, previously well drained; stir them together until nearly the whole of the hydroxide has dissolved, or until the Citric Acid is saturated with ferric hydroxide (prepared, if necessary, from more of the Solution of Ferric Sulphate); let the solution cool; add five and a half fluid ounces (Imp. meas.) or one hundred and ten cubic centimetres of Solution of Ammonia; filter through flannel, adding some Distilled Water if necessary; evaporate to the consistence of syrup, the presence of a very slight excess of ammonia being maintained; dry in thin layers on flat porcelain or glass plates at a temperature not exceeding 100° F. (37.8° C.); remove the dry flakes of Iron and Ammonium Citrate." Br.

In the U. S. Pharmacopœia 1890, the process consisted simply in evaporating a mixture of solution of ferric citrate and ammonia water. In the British, ferric hydroxide is first precipitated from a solution of the ferric sulphate, then digested at a moderate heat with a solution of citric acid, and lastly neutralized by ammonia. It has, however, been found by E. R. Squibb that a heat above 82.1° C. (180° F.) acts injuriously in the preparation of the ferric citrate, and the boiling heat directed in the British Pharmacopœia of 1864 was, therefore, improper. (*A. J. P.*, xxvii. 297.) This error has been corrected in the present Br. Pharmacopœia, which directs that the salt should be dried at a heat not above 38° C. (100° F.). In the U. S. 1890 formula the ferric citrate was used already prepared, in the British it is prepared in the process. The solution should be concentrated to a syrupy consistence before being poured out on porcelain or glass to dry, and it is important that the heat employed in the concentration should not exceed that indicated. Like most of the scaled iron salts, this preparation is not a true chemical compound, the ammonia not being in the proportion to form a double salt; it would be better to name it "ammoniated iron citrate."

J. U. Lloyd (*N. R.*, 1879, 323) states that it is usually difficult to adjust accurately the quantity of the ammonia in this process, and proposes to use a definite quantity of a fixed salt, like ammonium citrate, instead. His process will be found in the footnote.¹ R. Rother recommends the following method: Dissolve 272 parts of ferric citrate in three or four times its weight of water with heat, add 79 parts of ammonium carbonate, evaporate, and scale in the usual manner. (*A. J. P.*, 1887, p. 166.)

Properties.—Iron and ammonium citrate is more soluble than the citrate. It is in "thin, transparent, garnet-red scales, without odor, and having a saline, mildly ferruginous taste; deliquescent in moist air. Readily and completely soluble in water, but insoluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction with red litmus paper (absence of *citrates* or *tartrates* of the *alkali*

metals). An aqueous solution of the salt is neutral to litmus paper. The aqueous solution is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. the solution does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid (difference from *ferric citrate*). If Iron and Ammonium Citrate be heated with potassium hydroxide T.S., it yields a brownish-red precipitate, and ammonia is evolved. If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for twenty-four hours, should not yield a white, crystalline precipitate (absence of *tartrate*). If 0.555 Gm. of the salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 16 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as an indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." *U. S.* "When incinerated with free access of air, it leaves 31 or 32 per cent. of ferric oxide, which is not alkaline to *litmus* (absence of fixed alkali). Heated with *solution of potassium hydroxide* it evolves ammonia and deposits ferric hydroxide. The alkaline solution from which the iron has separated does not, when slightly supersaturated with *acetic acid*, give any crystalline precipitate (absence of *tartrates*). It should not yield more than the slightest characteristic reactions with the tests for sulphates." *Br.* Its precise chemical constitution is not determined; but Méhu (*Jahresb.*, 1873, 570), on evaporating a solution of ferrous citrate in ammonia to dryness, obtained a salt of the formula $\text{Fe}_2(\text{NH}_4)_2 \cdot 2(\text{C}_6\text{H}_5\text{O}_7)_2 + 3\text{H}_2\text{O}$.

Uses.—This salt is a pleasant chalybeate, in doses of 5 grains (0.32 Gm.). According to Paris, it may be mixed with the carbonated alkalies without decomposition, and given in a state of effervescence with citric acid. It should be prescribed when ferric citrate is desired in solution, as it is not suited for administration in the form of pills, owing to the presence of ammonia, which renders it too soluble, and causes the pills to flatten after they have been made, and frequently to cohere in one solid mass. The official ferric citrate should always be used for pills, as it is more slowly dissolved.

Dose, from three to eight grains (0.2 to 0.5 Gm.).

Off. Prep.—Vinum Ferri, *U. S.* (*Br.*).

¹ Prepare a solution of ammonium citrate from citric acid 8 oz. av., and ammonia water q. s.

Add the ammonia water to the citric acid until in slight excess, then evaporate the solution until it measures sixteen fluidounces.

Then take of solution of iron tersulphate 16 fluidounces; citric acid 4 ounces av.; distilled water and ammonia water, each, a sufficient quantity; solution of ammonium citrate 5 fluidounces. Prepare hydrated ferric oxide from the solution of iron tersulphate. Having drained it, place in an evaporating dish and add the citric acid, warm upon a steam or water bath, and stir until the citric acid is dissolved, then add the solution of ammonium citrate and stir until the hydrated oxide is dissolved, filter and evaporate to the consistence of thick syrup, spread upon glass with a brush, and dry. The yield will be 4234 grains.

FERRI ET AMMONII SULPHAS. U. S.

FERRIC AMMONIUM SULPHATE [Ammonio-Ferric Sulphate, Ammonio-Ferric Alum, Iron Ammonium Alum]

(fēr'ri ēt ăm-mō'nī-i sŭl'phās)

"It should contain, in the uneffloresced condition, 99.5 percent. of pure Ferric Ammonium Sulphate, and not less than 11.5 percent. of metallic iron. It should be kept in well-stoppered bottles, protected from light." U. S.

Ferrum Ammonio-Sulphuricum, Oxidatum Ammoniatum; Ferrum Ammonio-Sulphuricum, Ferri Ammonio-Sulphas, Sulphas Ammonio-Ferricus, Alumen Ammoniacale ferricum, Iron Alum; Sulfate de Fer et d'Ammoniaque, Sulfate de Fer (ferrique) ammoniacal, Alun de Fer ammoniacal, Fr.; Schwefelsaures Eisenoxyd-Ammonium, Ammoniakalischer Eisenaun, Ferriammoniumsulfat, G.

The present Pharmacopœia does not give a process for preparing this salt; that of the U. S. P. 1870 will be found below.¹

This is an ammonia iron-alum, in which the place of the aluminum oxide (alumina) is occupied by the ferric oxide. It is prepared by heating the solution of ferric tersulphate with ammonium sulphate until the latter salt is dissolved, and then allowing the solution to cool. The two salts unite to form iron and ammonium sulphate, which, being insoluble in the amount of liquid employed, crystallizes when it cools. The process is based on that of Wm. Hodgson (*A. J. P.*, 1856, p. 305).

Properties.—Ammonio-ferric alum is in "pale violet, octahedral crystals, without odor, and having an acid, styptic taste; efflorescent on exposure to the air. Soluble in 2.7 parts of water at 25° C. (77° F.), and in 0.8 part of boiling water; insoluble in alcohol. When strongly heated, the crystals fuse, lose their water of crystallization, expand, and finally leave a pale brown residue. The aqueous solution of the salt has a slightly acid reaction upon blue litmus paper, and yields with potassium ferrocyanide T.S. a blue precipitate, and with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. With potassium hydroxide T.S. Ferric Ammonium Sulphate yields a brownish-red precipitate, and if the mixture be heated, ammonia gas is evolved. If the iron be wholly precipitated from a solution of the salt by treating it with an excess of potassium hydroxide T.S., the resulting filtrate when neutralized with hydrochloric acid, and then mixed with ammonia water, should not yield a white, gelatinous precipitate (absence of aluminum). The addition of 3 Cc. of nitric acid to 30 Cc. of a solution of the salt (1 in

20), followed by a few drops of silver nitrate T.S., should not produce any turbidity (absence of chlorides). If 0.555 Gm. of the uneffloresced crystals of the salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 11.5 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron.)" U. S. According to H. Rose, the pure salt is white, and gives a colored solution with water, in consequence of the formation of a basic ferruginous salt. This decomposition is prevented by dissolving it in diluted sulphuric acid, when the solution is colorless. Instead of ammonium sulphate, potassium sulphate may be employed with the solution of ferric tersulphate, in which case a potassium iron-alum is produced, called *potassio-ferric alum*, which has all the properties, physical and remedial, of the ammonio-ferric salt, and the two appear to have been indiscriminately used.

Uses.—The iron-alums were brought to the notice of the Pharmaceutical Society of London in Dec. 1853, by Lindsley Blyth, as a new remedy, prescribed in St. Mary's Hospital. Tyler Smith found them to be more astringent than common alum, and devoid of the stimulating effects of the other salts of iron. Ferric alum is certainly useful in passive *leucorrhœas*, and its saturated solution has been strongly recommended as a styptic.

Dose, from five to ten grains (0.32 to 0.65 Gm.), to be repeated twice or three times a day.

FERRI ET AMMONII TARTRAS. U. S.

IRON AND AMMONIUM TARTRATE
[Ammonio-Ferric Tartrate]

(fēr'ri ēt ăm-mō'nī-i tār'trās)

"It should contain Iron and Ammonium Tartrate corresponding in amount to not less than 13 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light." U. S.

Ferrum Tartaricum Ammoniatum, Ferri Ammonio-Tartras; Ammonio-Tartrate of Iron; Tartrate Ferrico-ammonique, Fr. Cod.; Tartrate de Fer et d'Ammoniaque, Tartrate ferrigue ammoniacal, Fr.; Weinsaures Eisenoxyd-Ammonium, G.

No process is given in the U. S. P. (8th Rev.) for iron and ammonium tartrate. The process of the U. S. P. 1890 is appended.¹

¹ *Ferri et Ammonii Sulphas.*—"Take of Solution of Tersulphate of Iron two pints; Sulphate of Ammonium four troyounces and a half. Heat the Solution of Tersulphate of Iron to the boiling point, add the Sulphate of Ammonium, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air." U. S. 1870.

¹ "Solution of Ferric Sulphate, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Tartaric Acid, twenty-nine grammes [or 1 ounce av., 10 grains]; Distilled Water, two hundred cubic centimeters [or 6 fluidounces, 368 minims]; Ammonia Water, Water, each, a sufficient quantity. To one hundred and ten cubic centimeters [or 3 fluidounces,

Properties.—This salt is in "thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, slightly ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol. When strongly heated, the salt chars, emits fumes having the odor of burning sugar, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper (absence of *citrates* or *tartrates* of the *alkali metals*). An aqueous solution of Iron and Ammonium Tartrate should be neutral to litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. the solution does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid. If Iron and Ammonium Tartrate be heated with potassium hydroxide T.S., it yields a brownish-red precipitate, and ammonia is evolved. If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate. If 0.555 Gm. of the dry salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide,

and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 13 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." U. S.

Dose, as a mild chalybeate, from five to ten grains (0.32 to 0.65 Gm.).

FERRI ET POTASSII TARTRAS.

U. S. (Br.)

IRON AND POTASSIUM TARTRATE
[Potassio-Ferric Tartrate]

(fě'r-rī ēt pō-tās'sī-i tār'trās)

"It should contain Iron and Potassium Tartrate corresponding in amount to not less than 15 percent. of metallic iron, and should be kept in well-stoppered bottles, protected from light." U. S.

Ferrum Tartaratum, Br.; Tartarated Iron; Ferri Potassio-Tartras, Ferrum Tartarizatum, Tartras Ferrico-Potassicus, s. Potassico-Ferricus, s. Ferrico-Kallicus, Ferri-Kalium Tartaricum; Tartarated (tartarized) Iron, Ferro-Tartrate of Potassium; Tartrate Ferrico-potassique, *Fr. Cod.*; Tartrate de Fer et de Potasse, Tartrate Chalybé, Tartre martial, *Fr.*; Kaliumferritartrat, Weinsaures Eisenoxyd-Kali, Eisen Weinstein, *G.*; Tartrato ferrico-potassico, *It.*; Tartrato ferrico-potassico, *Sp.*

No process is given in the U. S. P. (8th Rev.) for iron and potassium tartrate; that of the former Pharmacopœia will be found below.¹

"Solution of Ferric Sulphate, 10 *fl. ounces* (Imperial measure) or 200 cubic centimetres; Solution of Ammonia, 16 *fl. ounces* or a suffi-

345 minims] of Ammonia Water, previously diluted with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of cold Water, add, with constant stirring, the Solution of Ferric Sulphate, previously diluted with thirteen hundred cubic centimeters [or 43 fluidounces, 460 minims] of cold Water. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, then mix the precipitate intimately with about fifteen hundred cubic centimeters [or 50 fluidounces, 346 minims] of cold Water, again draw off the clear liquid, and repeat the washing with Water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Then transfer the precipitate to a wet muslin strainer, allow it to drain, and express the water as completely as possible. Dissolve one-half of the Tartaric Acid in the Distilled Water, neutralize the solution exactly with Ammonia Water, then add the other half of the Tartaric Acid, and dissolve it by the application of a gentle heat. Now add the moist ferric hydrate, in successive portions, stirring constantly, and continue the heat, which should not exceed 60° C. (140° F.), until the hydrate is dissolved. Filter the solution while hot, evaporate it in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

This process does not differ essentially from that of Procter. (*A. J. P.*, 1841, p. 276.) Ammonium tartrate is prepared, which is converted into bitartrate by the addition of tartaric acid, and the excess of acid is then combined with ferric hydroxide freshly prepared from the official solution of ferric sulphate. A double salt of ammonium and iron tartrate is thus made in solution; by filtering, concentrating, and scaling, the salt is then obtained; this, theoretically, must be considered as consisting of one molecule of tartaric acid and two molecules of base, one consisting of ammonia and the other of ferric oxide, $2(\text{FeO})\text{NH}_4\text{C}_4\text{H}_4\text{O}_6\cdot 3\text{H}_2\text{O}$. It is hardly probable that the salt has exactly this chemical composition, as the scaled salts cannot be said to be definite compounds. The proportion of tartaric acid has been considerably reduced, as it was found to be excessive in previous formulas, and it might be diminished still further with advantage.

¹"Solution of Ferric Sulphate, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Potassium Bitartrate, thirty-eight grammes [or 1 ounce av., 148 grains]; Distilled Water, three hundred cubic centimeters [or 10 fluidounces, 69 minims]; Ammonia Water, Water, each, a sufficient quantity. To one hundred and ten cubic centimeters [or 3 fluidounces, 345 minims] of Ammonia Water, previously diluted with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of cold Water, add, under constant stirring, the Solution of Ferric Sulphate, previously diluted with thirteen hundred cubic centimeters [or 43 fluidounces, 460 minims] of cold Water. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, then mix the precipitate intimately with about fifteen hundred cubic centimeters [or 50 fluidounces, 346 minims] of cold Water, again draw off the clear liquid, and repeat the washing with Water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Then transfer the precipitate to a wet muslin strainer, allow it to drain, and express the water as completely as possible. Mix the Potassium Bitartrate with the Distilled Water in a porcelain vessel, heat the mixture, on a water-bath, to a temperature not exceeding 60° C. (140° F.), and gradually add the moist ferric hydrate, stirring constantly until it is dissolved. Filter the liquid while hot, and let the filtrate stand in a cool, dark place for twenty-four hours. Then stir it well with a porcelain or glass spatula, so that the precipitate which has formed in it may be thoroughly incorporated with the liquid. Now add, very cautiously, just enough Ammonia Water to dissolve the precipitate, evaporate the solution in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

cient quantity (Imp. meas.) or 320 cubic centimetres or a sufficient quantity; Acid Potassium Tartrate, in powder, 3 ounces and 146 grains (Imp.) or 66.5 grammes; Distilled Water, a sufficient quantity. Prepare ferric hydroxide from ten fluid ounces (Imp. meas.) or two hundred cubic centimetres of Solution of Ferric Sulphate as directed under 'Ferri et Ammonii Citras.'

Mix the ferric hydroxide intimately with the Acid Potassium Tartrate in a porcelain dish; let the mixture stand for twenty-four hours; heat to a temperature not exceeding 140° F. (60° C.), add gradually a pint and a half (Imp. meas.) or six hundred cubic centimetres of Distilled Water; stir constantly until nothing more will dissolve; filter; evaporate at a temperature not exceeding 140° F. (60° C.) to the consistence of syrup; dry in thin layers on flat porcelain or glass plates in a drying closet at a temperature not exceeding 100° F. (37.8° C.); remove the dry flakes of Tartarated Iron." Br.

The object of this process is to combine the excess of acid in the potassium bitartrate with ferric hydroxide. The plan of Soubeiran in the main is adopted,—namely, that of dissolving the moist ferric hydroxide to saturation in a mixture of the bitartrate and water, aided by a moderate heat. The oxide is obtained from the solution of ferric sulphate, which is precipitated by ammonia. Potassium hydroxide, which was used in the former British process, is not a good precipitant, because the alkali adheres obstinately to the precipitated oxide, and cannot be completely separated even by repeated washings. The oxide should be gradually added to the bitartrate and water, heated to 60° C. (140° F.), as recommended by Soubeiran, at which temperature the oxide dissolves more readily and in larger quantity than when a higher temperature is employed. Besides, in the latter case, a portion of the ferric oxide is converted into ferrous oxide. (*Gmelin's Handbook*, x. 315). In the U. S. 1890 process the addition of ammonia water to the cooled filtrate dissolves the precipitated insoluble ferric tartrate, and is in accordance with the recommendation of J. U. Lloyd (*N. R.*, 1879, p. 324), who asserts that this modification renders the salt more soluble without interfering with its stability. G. H. Chas. Klie suggested this improvement in *A. J. P.*, 1876, p. 170. (See also *N. R.*, 1878, p. 21.) In both formulas the liquid is poured out on a plane surface so as to dry in scales. When duly carried into effect, they yield a product at all times identical, and having all the required qualities of the salt. W. Lyon (*P. J.*, 1902, 530) proposes to substitute potassium and sodium tartrate for the acid potassium tartrate used in the British Pharm. process, believing that the resulting scaled salt will retain its ready solubility for a much longer time than will the official preparation; he uses the following proportions: Solution of ferric sulphate 300 Cc.; Solution of

ammonia 480 Cc. or a sufficient quantity; potassium and sodium tartrate 176 Gm. The official process and directions are otherwise followed. For Roger's process for this salt and the manufacture of *Boules de Mars* (balls of iron and potassium tartrate), see U. S. D., 17th ed., 611.

Use proposed *ferrous tartrate* for medicinal use. He made it by acting on clean iron filings, or bits of iron wire, with a solution of tartaric acid. It is a pulverulent salt, insoluble in water, and possessing a mild chalybeate taste.

Properties.—Iron and potassium tartrate is in "thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol. When strongly heated, the salt chars, emits fumes having an odor resembling that of burning sugar, and finally leaves a dark brown residue, having a strongly alkaline reaction, and effervescing with acids (distinction from *iron and ammonium tartrate*). An aqueous solution of Iron and Potassium Tartrate should be neutral to litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. the solution does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid. When heated with potassium hydroxide T.S., the salt yields a brownish-red precipitate. If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate. If 0.555 Gm. of the dry salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 15 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." U. S. "The aqueous solution, when acidulated with *hydrochloric acid*, affords a copious blue precipitate with *solution of potassium ferrocyanide*, but none or only a greenish turbidity with *solution of potassium ferricyanide*. When the salt is boiled with *solution of sodium hydroxide*, a reddish-brown precipitate separates, and the filtered solution, when slightly acidulated with *acetic acid*, yields, as it cools, a crystalline deposit, especially if the solution is previously mixed with a little *alcohol* (90 per cent.). By incinerating 10 grammes at a red heat, washing the residue with *water*, and again incinerating with free access of air, a residue of ferric oxide is obtained weighing not less than 3 grammes." Br. According to the view of its nature taken in the U. S. Pharmacopœia, it

is a double salt, consisting of one molecule of ferrie tartrate and one of potassium tartrate:

Flückiger (*Pharmaceutische Chemie*, 2d ed., 573, 1888), on the other hand, considers the salt formed to be one in which Fe_2O_3 is present as a bivalent group, and gives it the formula:

The salt is incompatible with astringent vegetable infusions, which give rise to a dark-colored precipitate.

Uses.—Iron and potassium tartrate is a mild, agreeable chalybeate, with but little astringency. It is well borne by the stomach, taken fasting or with the food. Its slight taste and ready solubility make it one of the best ferruginous preparations for children.

Dose, for an adult, five to ten grains (0.32 to 0.65 Gm.), given preferably in solution.

FERRI ET QUININÆ CITRAS.

U. S., Br.

IRON AND QUININE CITRATE

(fēr'ri èt qui-nī'næ cit'rās)

"It should contain not less than 11.5 per cent. of dried quinine, and ferrie citrate corresponding in amount to not less than 13.5 per cent. of metallic iron. It should be kept in well-stoppered bottles, protected from light." U. S.

Ferri et Quininæ Citras, Br. 1867, U. S. 1870; Citrate of Iron and Quinia; Citrate de Fer et de Quinine, Fr.; Chininum Ferro-Citricum, P. G.; Eisen-chinincitrat, Citronensaures Eisen-Chinin, G.

No process is given in the U. S. P. (8th Rev.) for iron and quinine citrate; the U. S. P. 1890 process is appended.¹

"Solution of Ferrie Sulphate, 9 fl. ounces (Imperial measure) or 180 cubic centimetres; Quinine Sulphate, 2 ounces (Imp.) or 40 grammes; Diluted Sulphuric Acid, 3 fl. ounces (Imp. meas.) or 60 cubic centimetres; Citric Acid, 6 ounces and 60 grains (Imp.) or 123 grammes; Solution of Ammonia, Distilled Water, of each, a sufficient quantity. Prepare ferrie hydroxide from nine fluid ounces (Imp. meas.) or two hundred cubic centimetres of Solution of Ferrie Sulphate as directed under 'Ferri et Ammonii Citras.'

¹ "Ferrie Citrate, eighty-five grammes [or 2 ounces av., 436 grains]; Quinine, dried at 100° C. (212° F.) to a constant weight, twelve grammes [or 186 grains]; Citric Acid, three grammes [or 46 grains]; Distilled Water, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Dissolve the Ferrie Citrate in one hundred and sixty cubic centimetres [or 5 fluidounces, 197 minims] of Distilled Water by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the Quinine and Citric Acid, previously triturated with twenty cubic centimetres [or 325 minims] of Distilled Water, and stir constantly until the Quinine and Citric Acid are dissolved. Lastly, evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

Mix the Quinine Sulphate with eight times its weight of Distilled Water; add the Diluted Sulphuric Acid; when the salt is dissolved precipitate the quinine with a slight excess of Solution of Ammonia; collect the precipitate on a filter; wash it with three pints (Imp. meas.) or twelve hundred cubic centimetres of Distilled Water.

Dissolve the Citric Acid in its own weight of Distilled Water; warm the solution on a water-bath; add the ferrie hydroxide, previously well drained; stir them together; when the hydroxide has dissolved, add the precipitated quinine; continue the agitation until this also has dissolved; let the solution cool; add, in small quantities at a time, three fluid ounces (Imp. meas.) or sixty cubic centimetres of Solution of Ammonia, diluted with four fluid ounces (Imp. meas.) or eighty cubic centimetres of Distilled Water; stir briskly, allowing the quinine which separates with each addition of ammonia to dissolve before the next addition is made; filter the solution; evaporate it to the consistence of a thick syrup; dry the latter in thin layers on flat porcelain or glass plates at a temperature of 100° F. (37.8° C.); remove the dry flakes of Iron and Quinine Citrate." Br.

The official iron and quinine citrate has never been very largely used, because of its slow solubility,¹ the manufacturers supplying

¹ *Liquor Ferri et Quininæ Citratis*, U. S. 1880. *Solution of Citrate of Iron and Quinine*. (Citrate de Fer et de Quinine liquide, Fr.; Citronensaures Eisen-Chinin-Lösung, G.)—"Citrate of Iron and Ammonium, sixty-five parts [or five hundred and sixty-eight grains]; Quinine, dried at 100° C. (212° F.), until it ceases to lose weight, twelve parts [or one hundred and five grains]; Citric Acid, twenty-eight parts [or two hundred and forty-five grains]; Alcohol, thirty parts [or six fluidrachms]; Distilled Water, a sufficient quantity, to make two hundred parts [or four ounces av.]. Dissolve the Citrate of Iron and Ammonium in two hundred parts [or four fluidounces] of Distilled Water, contained in a tared porcelain capsule, heat the solution to 60° C. (140° F.), on a water-bath, add the Citric Acid, and, when it is dissolved, add the Quinine, stirring the mixture until a perfect solution has been obtained. Evaporate this to one hundred and sixty parts [or three ounces av.], allow it to cool, add the Alcohol, and finally enough Distilled Water to make the solution weigh two hundred parts [or four ounces av.]." U. S. 1880.

The introduction of this solution in the U. S. P. 1880 grew out of the necessity for a soluble form of iron and quinine citrate. That comparatively insoluble salt, the official iron and quinine citrate, has been but little used, while the readily soluble preparation of the manufacturers, which contained ammonia, was in extensive demand, and is now official. It was believed that the above solution would come into use, as it bears a definite and easily remembered relation toward the official salt (see *Ferri et Quininæ Citras*), being exactly half its strength, but these expectations were not realized, and the solution was not introduced into the U. S. P. 1890 or 8th Revisions.

Properties.—"A dark greenish-yellow to yellowish-brown liquid, transparent in thin layers, odorless, having a bitter and mildly ferruginous taste, and a slightly acid reaction. On supersaturating the diluted solution with a slight excess of ammonia, the color of the liquid is deepened and a white, curdy precipitate is thrown down, which is soluble in ether and answers to the reaction of quinine (see *Quinina*). A small portion of the filtrate, when mixed with test-solution of potassium ferrocyanide, does not produce a blue color or precipitate, unless it is acidulated with hydrochloric acid. If another portion of the filtrate be deprived of its iron, by boiling with an excess of potassa, the concentrated and cooled filtrate precipitated by test-solution of

a salt which is readily soluble, due to the presence of ammonia. But by the introduction of a soluble iron and quinine citrate (see *Ferri et Quinina Citras Solubilis*) the salt is now furnished in a very convenient form for use in solutions, while the above comparatively insoluble salt may be retained for use in pills, for which it is much better adapted. The British Pharmacopœia preparation contains ammonium citrate and is therefore more like the soluble citrate of iron and quinine of the U. S. P. 8th Rev.

The use of ferrous sulphate by the former British process was abandoned, and the solution of ferric sulphate retained. From this the freshly precipitated ferric hydroxide is obtained by precipitation with ammonia. The next step is to separate quinine from the sulphate, by simply dissolving the salt in water with the aid of sulphuric acid, and then precipitating by ammonia. Thirdly, the hydroxide and quinine are dissolved successively, aided by the heat of a water bath, in solution of citric acid, whereby an iron and quinine citrate is obtained. The ammonia is added in order to render the iron and quinine citrate more soluble by the agency of a portion of ammonium citrate. It is important that the ammonia should not be added in excess; on the contrary, the solution should retain a slight acid reaction. (Fleurot.) After evaporation, the salt is dried, as in the other process, on glass or porcelain, so as to be obtained in thin scales.

No analysis has been made that determines precisely the chemical composition of this "scaled salt." It is undoubtedly a mere mixture of the iron and quinine citrates, the British containing ammonium citrate.

The characters of the U. S. salt, as given in the Pharmacopœia, are the following: "Thin, transparent scales, of a reddish-brown color, without odor, and having a bitter, mildly ferruginous taste; slowly deliquescent. Slowly but completely soluble in cold water, more readily soluble in hot water, partially soluble in alcohol. Its solubility is diminished by age. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper (absence of citrates or tartrates of the alkali metals). The aqueous solution of the salt shows an acid reaction with blue litmus

calcium chloride, and the new filtrate heated to boiling, a white granular precipitate is produced. On heating the solution with potassa, vapor of ammonia is evolved. The solution contains 6 per cent. of quinine. It may be assayed as follows: Dilute 8 Gm. of the solution with water to 30 Cc., introduce it, with any rinsings, into a glass separator, add an aqueous solution of 0.5 Gm. of tartaric acid, and then solution of soda in decided excess. Extract the alkaloid by agitating the mixture with four successive portions of chloroform, each of 15 Cc. Separate the chloroformic layers, mix them, evaporate them in a weighed capsule, on a water bath, and dry the residue at a temperature of 100° C. (212° F.). It should weigh 0.48 Gm." U. S. 1880.

Uses.—The medicinal virtues of this solution are those of iron and quinine citrate. It may be given in the dose of from 10 to 20 minims (0.6 to 1.3 Cc.).

paper. On the addition of a slight excess of ammonia water the color of the solution is deepened, and a white, curdy precipitate is produced. The filtrate from this precipitate does not afford a blue color with potassium ferrocyanide T.S., unless it be acidulated with hydrochloric acid. Another portion of the filtrate, heated with an excess of potassium hydroxide T.S., deposits a brownish-red precipitate. If an aqueous solution of the salt (1 in 10) be deprived of its iron and quinine by boiling with an excess of potassium hydroxide T.S., and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, gradually deposits a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate (absence of tartrate)." U. S.

Assay for the Quinine.—"Introduce 1.11 Gm. of Iron and Quinine Citrate into a dish, and, with the aid of a gentle heat, dissolve it in 20 Cc. of water. Transfer the solution, together with the rinsings of the dish, to a separator, allow the liquid to become cold, then add 5 Cc. of ammonia water and 10 Cc. of chloroform, and shake the separator for one minute. Allow the liquids to separate, draw off the chloroformic layer, and shake the residuary liquid a second and a third time with portions of 10 Cc. each of chloroform. Allow the combined chloroformic solutions to evaporate spontaneously in a tared dish, and dry the residue at 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0.1276 Gm. (corresponding to at least 11.5 percent. of dried quinine), and should conform to the reactions and tests under *Quinina*.

Assay for the Iron.—Heat the aqueous liquid, from which the quinine has been removed in the manner just described, on a water-bath, until the odor of chloroform and of ammonia have disappeared, allow it to cool, and dilute it with water to the volume of 50 Cc. Transfer 25 Cc. of the liquid to a glass-stoppered flask having the capacity of about 100 Cc., add 3 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and, after securely closing the flask, allow the mixture to stand for half an hour at 40° C. (104° F.). After it has been allowed to cool, it should require not less than 13.5 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." U. S.

The British Pharmacopœia (1898) gives the following description and tests: "In thin scales of a greenish golden-yellow color, somewhat deliquescent. Soluble in half its weight of cold water. The solution is very slightly acid, and yields precipitates which are reddish brown with solution of potassium hydroxide,

white with solution of ammonia, blue with solution of potassium ferrocyanide and with solution of potassium ferricyanide, and grayish black with solution of tannic acid. The salt has a bitter, chalybeate taste. When incinerated with free access of air, it leaves a residue which when moistened with water is not alkaline to test-paper (absence of fixed alkali). 5 grammes dissolved in 45 cubic centimetres of water and treated with a slight excess of solution of ammonia should yield a white precipitate, which, when dissolved out by repeated treatment of the liquid with ether, and the latter evaporated, and the residue completely dried at 248° F. (120° C.), weighs 0.75 gramme. This precipitate is almost entirely soluble in a little purified ether; when burned it leaves but a minute residue; neutralized by sulphuric acid, it should answer to the characters of and tests for Quinine Sulphate." Br.

Owing to the comparative cheapness of the alkaloid quinine at the present time the tendency to substitute other cinchona alkaloids has greatly diminished, and the introduction of an official assay process furnishes an excellent check to these practices.

Amorphous quinine or chinoidine was sometimes substituted for the crystallizable alkaloid. For the detection of this fraud, de Vrij proposed a method which depended upon the fact that oxalic acid forms with crystallizable quinine, in a chloroformic solution, white crystals of quinine oxalate without discoloration. (See N. R., 1881, 10.)

When dissolved by the aid of an acid, it forms a solution which, decolorized by a little purified animal charcoal, turns the plane of polarization strongly to the left,—a character of quinine, cinchonine turning it to the right. (Squire.) The salt is said to be sometimes adulterated by cinchonine, which would be at once detected by the test of solubility in ether and the effect on polarized light, above given. Oscar Zinn (*A. J. P.*, 1877, 550) examined six commercial samples, two of which contained no quinine, but cinchonine. H. G. Drueding found three out of six samples deficient in quinine. As it occurs in the British market, it is of exceedingly variable composition, containing, according to J. C. Braithwaite, who examined thirty-five different specimens, a proportion of quinine varying from 1.5 to 17 per cent. (*P. J.*, 1868, 157.) The proportion of alkaloid appears to be usually below the standard. (A. W. Gerrard, *Ibid.*, March, 1873, 763.) According to C. H. Wood (*Ibid.*, 2d ser., x. 644), this salt undergoes a rapid change of composition when exposed to the influence of the direct rays of the sun.

The official process of assay will doubtless bring to light all shortcomings. (See results of examination of commercial iron and quinine citrate by E. C. Federer, *Proc. Mich. Pharm. Assoc.*, 1887, or *Ph. Era*, 1887, p. 357.)

Iron and quinine citrate combines the virtues of its two bases, and may be given in all cases in which they are jointly indicated, preferably in pill form.

Dose, as a tonic, five or six grains (0.32 to 0.4 Gm.), containing about half a grain (0.032 Gm.) of dry quinine, three or four times a day. This dose may be increased if desired.

FERRI ET QUININÆ CITRAS SOLUBILIS. U. S.

SOLUBLE IRON AND QUININE CITRATE

(fēr'ri ēt quī-nī'næ cī'trās sō-lū'bī-līs)

"It should contain not less than 11.5 per cent. of dried quinine, and ferric citrate corresponding in amount to not less than 13.5 per cent. of metallic iron. It should be kept in well-stoppered bottles, protected from light." U. S.

The U. S. P. (8th Rev.) does not contain a process for soluble iron and quinine citrate; the U. S. P. 1890 process is as follows: "Ferric Citrate, *eighty-five grammes* [or 2 ounces av., 436 grains]; Quinine, dried at 100° C. (212° F.) to a constant weight, *twelve grammes* [or 186 grains]; Citric Acid, *three grammes* [or 46 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity*, to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Ferric Citrate in *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims] of Distilled Water, by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the Quinine and Citric Acid previously triturated with *twenty cubic centimeters* [or 325 minims] of Distilled Water, and stir constantly until the Quinine and Citric Acid are dissolved. Then add gradually, and with constant stirring, *fifty cubic centimeters* [or 1 fluidounce, 331 minims], or *a sufficient quantity*, of Ammonia Water, so that, after the addition of each portion of the latter, the precipitated Quinine will be redissolved and the liquid acquire a greenish-yellow tint. Lastly, evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

This official preparation was first added to the list in 1890, in answer to a demand which was very persistent. The iron and quinine citrate formerly official and the one in the U. S. P. (8th Rev.) are comparatively insoluble salts, and better adapted for use in pills; but the combination of iron, quinine, and citric acid is wanted more frequently in solution, and hence a salt which can be quickly dissolved is a desirable addition; the only difference between the two salts consists in greater solu-

bility, and this is effected by the use of ammonia water. See *Liquor Ferri et Quinina Citratis*, U. S. P. 1880, page 501.

Properties.—The U. S. Pharmacopœia (8th Rev.) describes it as in "thin, transparent scales, of a greenish, golden-yellow color, without odor, and having a bitter, mildly ferruginous taste; deliquescent. Rapidly and completely soluble in cold water, partially soluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction upon red litmus paper (absence of *citrates* or *tartrates* of the *alkali metals*). An aqueous solution of the salt shows a slightly acid reaction with blue litmus paper. On the addition of a slight excess of ammonia water the color of the liquid is deepened, and a white, curdy precipitate is produced. With potassium ferrocyanide T.S. a portion of the filtrate from this precipitate does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid. When heated with potassium hydroxide T.S., the salt affords a brownish-red precipitate, and ammonia is evolved. If an aqueous solution of the salt (1 in 10) be deprived of its iron and quinine by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for twenty-four hours, should not give a white, crystalline precipitate (absence of *tartrate*). Soluble Iron and Quinine Citrate, when assayed for Quinine and Iron by the method described under *Ferri et Quinina Citras*, should respond to the same requirements as the latter." U. S. See modification of process by F. A. Sieker (*Ph. Rund.*, 1895, 36).

Uses.—Soluble iron and quinine citrate is employed medicinally for the same purposes as iron and quinine citrate (see page 501).

Off. Prep.—Vinum Ferri Amarum, U. S.

FERRI ET STRYCHNINÆ CITRAS.

U. S.

IRON AND STRYCHNINE CITRATE

(fēr'i ēt strĕch-nī'næ cī'trās)

"It should contain not less than 0.9 nor more than 1 percent. of strychnine, and ferric citrate corresponding in amount to not less than 16 percent. of metallic iron. It should be kept in well-stoppered bottles, protected from light." U. S.

Ferri et Strychnina Citras, U. S. 1870; Citrate de Fer et de Strychnine, Fr.; Citronensaures Eisen-Strychnin, G.

The U. S. P. (8th. Rev.) does not contain a process for this preparation; that of the U. S. P. 1890 is as follows: "Iron and

Ammonium Citrate, *ninety-eight grammes* [or 3 ounces av., 200 grains]; Strychnine, *one gramme* [or 15.4 grains]; Citric Acid, *one gramme* [or 15.4 grains]; Distilled Water, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 27 minims], to make *one hundred grammes* [or 3 ounces av., 230 grains]. Dissolve the Iron and Ammonium Citrate in *one hundred cubic centimeters* [or 3 fluidounces, 181 minims] of Distilled Water, and the Strychnine, together with the Citric Acid, in *twenty cubic centimeters* [or 325 minims] of Distilled Water. Mix the two solutions, evaporate the mixture by means of a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

Iron and strychnine citrate, although long used in medicine, was first recognized in the U. S. P. 1870. The U. S. P. 1890 formula did not differ essentially from that of the U. S. P. 1870.

This salt is well adapted for administration in pillular form, but should never be prescribed in solution. E. R. Squibb has shown that a whitish deposit will begin to settle from the solution within two or three hours after it is made, and continue to increase for several days; the deposit was found to contain fifty per cent. of strychnine. When ammonia water or ammonium citrate was added, the precipitate was redissolved, but the solution could not be made permanent by the addition, as the precipitate reappeared. There might be dangerous or alarming symptoms if this solution were dispensed without shaking. (*Ephem.*, June, 1888, p. 1128.)

Properties.—It is officially described as in "thin, transparent scales, varying in color from garnet-red to yellowish-brown, without odor, and having a bitter, slightly ferruginous taste; deliquescent in moist air. Readily and completely soluble in water, partially soluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which, when moistened with hot water, should not show an alkaline reaction with red litmus paper (absence of *citrates* or *tartrates* of the *alkali metals*). The aqueous solution of Iron and Strychnine Citrate is slightly acid to litmus paper, and is not immediately precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. the aqueous solution does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid. On heating with potassium hydroxide T.S. the salt affords a brownish-red precipitate, evolving ammonia. If an aqueous solution of the salt (1 in 10) be deprived of its iron and strychnine by boiling with an excess of potassium hydroxide T.S., and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, when mixed with a little calcium chloride T.S., and again heated to boiling, will gradually

deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for twenty-four hours, should not deposit a white crystalline precipitate (absence of *tartrate*).” *U. S.*

Assay for the Strychnine.—“Dissolve 4.44 Gm. of Iron and Strychnine Citrate, in a separator, in 15 Cc. of water, add 5 Cc. of ammonia water and 10 Cc. of chloroform, and shake the separator for one minute.** Allow the liquids to separate, draw off the chloroformic layer, and shake the residuary liquid a second and a third time with portions of 10 Cc. each of chloroform. Allow the combined chloroformic liquids to evaporate spontaneously in a tared dish, and dry the residue at 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0.04 (0.0399) Gm., nor more than 0.0444 Gm. (corresponding to not less than 0.9 nor more than 1 percent. of strychnine), and should respond to the reactions and tests given under *Strychnina*.

Assay for the Iron.—Heat the aqueous liquid, from which the strychnine has been removed in the manner just described, on a water-bath, until the odors of chloroform and of ammonia have disappeared, allow it to cool, and dilute it with water to the volume of 100 Cc. Transfer 25 Cc. of the liquid to a glass-stoppered flask having the capacity of about 100 Cc., add 4 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and, after securely closing the flask, allow the mixture to stand for half an hour at 40° C. (104° F.). After it has been allowed to cool, it should require not less than 32 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of tenth-normal sodium thiosulphate V.S. indicating one-half percent. of metallic iron).” *U. S.* It contains 1 per cent. of strychnine, there being in five grains one-twentieth of a grain of the alkaloid.

Uses.—It is an efficient tonic, but has no advantages over the two active substances it contains when given conjointly in an uncombined state, and has the great disadvantage that the dose of one principle cannot be varied independently of that of the other.

Dose, from three to five grains (0.20 to 0.32 Gm.), in pill.

FERRI HYDROXIDUM. *U. S.*

FERRIC HYDROXIDE [Ferri Oxidum Hydratum, Pharm.
1890, Ferric Hydrate, Hydrated Oxide of Iron]

(fēr'ri hÿ-drōx'ĭ-dŭm)

$\text{Fe}(\text{OH})_3 = 106.14$

Ferri Peroxidum, Ferri Sesquioxidum; Ferri Oxidum Rubrum; Hydrous Peroxide of Iron; Ferric Oxyhydrate; Ferrugo; Hydrated Peroxide of Iron, Hydrated Oxide of Iron, Hydrated Sesquioxide of Iron, Moist Peroxide of Iron; Hydras Ferricus; Oxyde (sesqui) de fer Bihydraté, *Fr. Cod.*; Sesquioxide (Peroxide) de Fer hydraté humide, Hydrate de Peroxyde de Fer gélatineux, *Fr.*; Feuchtes Eisenoxydhydrat, Gegengift der Arsenigensaure, *G.*; Ossido ferrico idrato, *It.*; Hidrato ferrico gelatinoso, *Sp.*

* “Solution of Ferric Sulphate, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Ammonia Water, one hundred and thirty-eight cubic centimeters [or 4 fluidounces, 320 minims]; Water, a sufficient quantity. To the Ammonia Water, previously diluted with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of cold Water, add, with constant stirring, the Solution of Ferric Sulphate, previously diluted with one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of cold Water. As soon as the precipitate has subsided, draw off the clear liquid by means of a siphon, then mix the precipitate intimately with about one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of cold Water, again draw off the clear liquid after subsidence of the precipitate, and repeat this operation, until a portion of the decanted liquid gives not more than a slight cloudiness with barium chloride test solution. Finally, transfer the precipitate to a wet muslin strainer, and, after it has drained, mix it with sufficient cold Water to make the mixture weigh three hundred grammes [or 10 ounces av., 255 grains].” *U. S.*

This preparation was introduced into the *U. S. Pharmacopœia* on account of its importance as an antidote to arsenic trioxide or arsenous acid. It is frequently used in the official processes as the source of iron when it is desired to produce a ferric compound, but the directions for making it always accompany the preparation in which it is used, because of the difficulty of preserving the ferric hydroxide. In the former processes the first step was to convert ferrous sulphate into ferric sulphate; but in the present, the official solution of ferric sulphate is taken already containing the iron in the proper state of oxidation. This is simply treated with ammonia water (*U. S.*), which throws down the oxide combined with water, constituting the hydrated oxide required.

It is the duty of the apothecary to be always prepared to make this antidote, by keeping the necessary solutions for its precipitation. Magnesia is probably a better precipitant than ammonia water. (See next article.) In most cases of arsenical poisoning, minutes are of immense importance, and time must be lost in washing the precipitated iron if the official process be adhered to. Magnesia is not only not irritant, but is itself antidotal to arsenic; so that the precipitated mass may be given at once to the patient. The hydroxide should not be kept in stock, but when ordered as an antidote should be freshly prepared.

The British Pharmacopœia (1898) no longer includes ferric hydroxide. This is to be regretted, for, although not a stable preparation, an official process to be used in the emergency arising from arsenical poison should be quickly available; in our opinion every Pharmacopœia should contain an official antidote to arsenic.

Properties.—Ferric hydroxidé, as directed by the *U. S.* formula, “is a brownish-red

magma, wholly soluble in hydrochloric acid without effervescence." U. S. As prepared by the Dublin process, in which it was heated to redness, it lost the second molecule of water, and became the anhydrous sesquioxide (Fe_2O_3), identical with the *colcothar* of commerce.

The monohydrated sesquioxide is a reddish-brown, tasteless, insoluble powder, differing from colcothar in containing a molecule of water. Hence, "heated to dull redness in a test-tube it yields about 10 per cent. of moisture." Br. (1885). It should not be deliquescent, and should dissolve entirely in hydrochloric acid without effervescence. Its solution in diluted hydrochloric acid yields a copious blue precipitate with potassium ferrocyanide, but none with the ferricyanide, showing that it contains ferric oxide but no ferrous oxide. If it contains copper, its hydrochloric solution will deposit this metal on a bright piece of iron. Dawies states that if the hydrated oxide recently prepared be kept for four days in boiling water it loses a large proportion of its water, containing at the end of that time only 5.77 per cent.; the larger portion of the oxide has, therefore, become dehydrated, and the same thing happens at a lower temperature, 41.1°C . (106°F .), as in two or three months it becomes of a brick-red color, and is but slightly soluble in nitric acid. (J. P. C., 4e sér., iv. 400.) This oxide is not used as a medicine. It was employed in making iron plaster, *Emplastrum Ferri* (U. S. P. 1890), troches of iron, *Trochisci Ferri* (U. S. P. 1890), and reduced iron, for which purposes other forms of oxidized iron would answer as well. The former Dublin *rubigo ferri*, or *rust of iron*, formed by exposing moistened iron wire to the air until converted into rust, is essentially the sesquioxide, containing a little ferric carbonate, and does not differ materially from the iron subcarbonate formerly official.¹

¹ *Ferri Subcarbonas*, U. S. 1870; *Subcarbonate of Iron*; *Sesquioxide of Iron*; *Red Oxide of Iron*; *Precipitated Carbonate of Iron*; *Aperitive Saffron of Mars*.—"Take of Sulphate of Iron eight troyounces; Carbonate of Sodium nine troyounces; Water eight pints. Dissolve the salts separately, each in four pints of the Water; then mix the solutions thoroughly, and set aside the mixture until the precipitate has subsided. Then pour off the supernatant liquid, wash the precipitate with water until the washings pass nearly tasteless, and dry it on bibulous paper without heat." U. S. 1870.

When the solutions of sodium carbonate and ferrous sulphate are mixed together, a hydrated ferrous carbonate, of a pale-blue color, is thrown down, and sodium sulphate remains in solution. The precipitate during the washing and drying absorbs oxygen and loses nearly all its carbon dioxide, whereby it is converted almost entirely into ferric oxide. The direction to dry the precipitate without heat is important, as even a moderate elevation of temperature has been shown by the experiments of J. A. Rex to modify the resulting product unfavorably, diminishing its solubility in hydrochloric acid in proportion to the heat employed. (A. J. P., May, 1862, p. 193.)

Properties.—Ferric carbonate is a reddish-brown powder, of a disagreeable, slightly styptic taste, insoluble in water, and not readily dissolved by any acid except hydrochloric, with which it effervesces slightly. When of a bright red color it should be rejected, as this color shows that it has been injured by exposure to heat. After precipitation from its hydrochloric solution by ammonia or potassium

If exposed to a red heat it loses the combined water, and becomes the anhydrous sesquioxide, less easily soluble in acids, improper for medicinal use, and altogether without effect as an antidote. Kept for some time in the pulpy state, it loses half its combined water, and becomes less soluble in acids and less efficient as an antidote. Hirsch has given some useful details in making precipitated ferric oxide upon a comparatively large scale, in *Am. Drug.*, 1884, 66.

Uses.—Ferric hydroxide is not an eligible ferruginous preparation for medicinal use. Its antidotal powers in poisoning by arsenic, the manner in which it acts, the circumstances which impair its efficiency, and the mode of using it, are fully explained under *Arseni Trioxidum*. Its power of rendering arsenic trioxide insoluble is readily shown by agitating a solution of the acid with a considerable excess of the moist oxide, filtering, and then testing the filtered solution for the arsenic; not a trace of the metal can be detected, even by hydrogen sulphide. It is stated, however, to be inferior as an antidote to the saccharated oxide. Ferric hydroxide as obtained by the U. S. formula contains a little ammonia, which is thought by some to assist its antidotal powers. At least it has been ascertained that the sesquioxide when precipitated by potassium hydroxide, as formerly directed by the Dublin College, is less efficient than when precipitated by ammonia, and must be employed in quantities three or four times as large to produce the same effect. The dry hydroxide rubbed up with water is in the same proportion weaker than the pulpy hydroxide. Ferric carbonate (formerly official) possesses antidotal powers to arsenic, though in an inferior degree; but this statement will not apply to it after it has been exposed to a red heat, to which it is improperly subjected by some manufacturing chemists. By ignition it becomes anhydrous, and altogether inefficient as an antidote.

FERRI HYDROXIDUM CUM MAGNESII OXIDO. U. S.

FERRIC HYDROXIDE WITH MAGNESIUM OXIDE
[*Ferri Oxidum Hydratum cum Magnesia*, Pharm. 1890,
Arsenic Antidote, Ferric Hydrate with Magnesia]

(fēr'ri hÿ-drōx'î-dûm cûm mäg-nē'sî-i ôx'î-dô)

Antidotum Arsenici; Antidote to Arsenious Acid; Hydrated Oxide of Iron with Magnesia; Contre-poison de l'arsenic, Fr.; Gegengift des Arseniks, Gegengift der Arsenigensaure, G.; Hidrato ferrico magnesico, Sp.

hydroxide, either of which throws down ferric oxide, the supernatant liquor should give no indications of containing any metal in solution by the test of hydrogen sulphide or potassium ferrocyanide. It is incompatible with acids and acidulous salts. In composition it is a hydrated ferric oxide containing a little ferrous carbonate. By exposure to a red heat, it absorbs oxygen and loses water and carbon dioxide, being converted into the *astringent saffron of Mars* of the French Codex.

Uses.—Ferric carbonate is a rather feeble ferruginous tonic, nearly free from astringency. It has been especially commended in *neuralgia* in doses of a teaspoonful (3.75 Cc.). Dose, five grains (0.32 Gm.).

* "Solution of Ferric Sulphate, *forty cubic centimeters* [or 1 fluidounce, 169 minims]; Magnesium Oxide, *ten grammes* [or 154 grains]; Water, *a sufficient quantity*. Mix the Solution of Ferric Sulphate with *one hundred and twenty-five cubic centimeters* [or 4 fluidounces, 109 minims] of Water, and keep the liquid in a large, well-stoppered bottle. Rub the Magnesium Oxide with cold Water to a smooth and thin mixture, transfer this to a bottle capable of holding about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms], and fill it with Water to about three-fourths of its capacity. When the preparation is wanted for use, shake the Magnesium Oxide mixture to a homogeneous, thin magma, add it gradually to the diluted Solution of Ferric Sulphate, and shake them together until a uniform, smooth mixture results.

NOTE.—For the rapid preparation of this antidote to arsenical poisoning, the diluted Solution of Ferric Sulphate, and the mixture of Magnesium Oxide with Water, should always be kept on hand, in separate bottles, ready for immediate use." *U. S.*

This is a preparation which has been introduced for the purpose of furnishing a ready and efficient antidote against arsenic trioxide or arsenous acid. It is almost identical with the *Antidotum Arsenici* of the German Pharmacopœia, and experience has shown its effectiveness. Ferric hydroxide is produced when the mixture of magnesia is added to the diluted solution of ferric sulphate, and, as the magnesia is in excess and acidity thus prevented, no harm can result from not separating the by-products of the reaction. When mixed as officially directed, and ready for use, it contains ferric hydroxide with magnesium sulphate and hydroxide. It has been shown that no soluble compound with arsenic is formed when it is used as an antidote, and the presence of the magnesium salt, from a therapeutical point of view, is not at all objectionable. (See *Arseni Trioxidum*, p. 197.)

Dose, four fluidounces (120 Cc.).

FERRI HYPOPHOSPHIS. U. S.

FERRIC HYPOPHOSPHITE

(fēr'ri hÿ-pō-phōs'phis)

$\text{Fe}(\text{PH}_2\text{O}_2)_3 = 249.09$

"It should contain not less than 98 percent. of pure Ferric Hypophosphite [$(\text{PH}_2\text{O}.\text{O})_3\text{Fe}$], and should be kept in well-stoppered bottles." *U. S.*

Hypophosphite of Iron; Ferrum Hypophosphorolum, Hypophosphis Ferricus; Hypophosphite de Fer, *Fr.*; Unterphosphorigsaures Eisenoxyd, *Ferrihypophosphit*, *G.*

This is among the hypophosphites brought into notice in consequence of their recommendation by Churchill in the treatment of phthisis, in which they were thought to be useful by

the introduction of phosphorus into the system. This particular salt may be considered preferable to others when a marked condition of anæmia indicates a deficiency of iron in the tissues. It may be made by the action of hypophosphorous acid on ferrous carbonate formed by precipitation from the sulphate; but as some difficulty has been found in obtaining this acid perfectly pure, C. H. Wood of London, prefers the plan of double decomposition. He proposes that ferrous sulphate and calcium hypophosphite be made to react on each other in molecular proportions represented by 480 grains of crystallized ferrous sulphate and 326 grains of commercial hypophosphite: in the latter an allowance of 10 per cent. being made for impurities ordinarily found in that salt. These quantities will yield 320 grains of ferric hypophosphite, and the reaction will be represented by the following formula:

Calcium sulphate is precipitated, and ferrous hypophosphite is held in solution. (*P. J.*, 1868, p. 342.) In this condition the salt is a ferrous compound; but on evaporation the ferrous salt becomes ferric, and acquires the properties detailed in the Pharmacopœia. Of this the following description is given in the 8th revision of this work.

Properties.—"A white, or grayish-white powder, odorless and nearly tasteless; permanent in the air. Soluble in 2300 parts of water at 25° C. (77° F.), and in 1200 parts of boiling water; more readily soluble in the presence of hypophosphorous acid, or in a warm, concentrated solution of an alkali citrate, forming with the latter a green solution. When strongly heated in a dry test-tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and, on complete ignition, leaves a residue of ferric pyrophosphate. Ferric Hypophosphite is readily oxidized by nitric acid or other oxidizing agents. If to 1 Gm. of the salt 10 Cc. of acetic acid be added, no effervescence should occur (absence of carbonate), and if the mixture be subsequently heated to boiling, the filtrate should respond to the following tests: The addition of a few drops of silver nitrate T.S. to a portion of the filtrate should, upon warming, cause a brown to black coloration or precipitate. If another portion of the filtrate be added drop by drop to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed upon gently heating. Another portion of the cold filtrate should afford no turbidity with ammonium oxalate T.S. (absence of calcium). If 0.5 Gm. of the salt be boiled with 10 Cc. of potassium hydroxide T.S., a reddish-brown precipitate will be produced; and if to the filtrate from the latter, slightly acidulated with hydrochloric acid, magnesia mixture T.S. be added, and subsequently an excess of ammonia water, no crystalline precipitate should be produced (absence of phosphate). If 1 Gm. of

the salt be dissolved in about 25 Cc. of boiling water by the aid of sufficient hydrochloric acid, added drop by drop, then a slight excess of ammonia water added, the filtrate from the reddish-brown precipitate should be colorless, and, after acidulating with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121.)" *U. S.*

Syrup of ferrous hypophosphite may be prepared by simply adding syrup to the solution of the hypophosphite remaining after the separation of the calcium sulphate in the process of Wood above given. If two and a half ounces of water be used in the process, and the paste resulting from the precipitation of the calcium sulphate be pressed out, the remaining liquid, after filtration, will form with seven times its volume of syrup a liquid containing two grains of the hypophosphite in a fluidrachm. (*P. J.*, April, 1868.) But in this form, if the syrup be not thoroughly protected it quickly absorbs oxygen, and in a few hours begins to exhibit the formation of a precipitate, rendering it in a short time unfit for use. A little phosphoric or citric acid added to the syrup will obviate this result; but it is better perhaps at once to form a syrup from materials which will not be liable to this objection.

Wood employs the following process: "Take of granulated ferrous sulphate 480 gr., calcium hypophosphite 326 gr., diluted phosphoric acid 1 fl. oz., water 1½ fl. oz., syrup, a sufficient quantity. Dissolve, without heat, the ferrous sulphate in the phosphoric acid, previously mixed with the water. Rub the hypophosphite to fine powder, and pour on it the solution of the sulphate. Triturate together for two or three minutes, then pour the mixture on a piece of damp calico, and squeeze out the liquid with the hands. Filter this solution, and add to it seven times its volume of strong syrup. The resulting syrup will contain two grains of ferrie hypophosphite in each fluidrachm." The dose may be from two to six fluidrachms (7.5 to 22.50 Cc.).

C. L. Diehl prepares a *syrup of ferrie hypophosphite* from a freshly precipitated magma produced by precipitating a solution of calcium hypophosphite with solution of ferrie chloride and dissolving the magma by the aid of potassium citrate. (*Proc. A. Ph. A.*, 1882, 71.)

Uses.—Ferrie hypophosphite may be given in states of the system where deficient powers of the cerebral centres are attended with an anæmic condition of the blood. It has been especially employed in *phthisis* and allied cachexias. It may be administered in the form of pill or powder, but the syrup is more elegant.

Dose, from five to ten grains (0.32 to 0.65 Gm.).

Off. Prep.—Syrupus Hypophosphitum Compositus, *U. S.*

FERRI PHOSPHAS. Br.

IRON PHOSPHATE

(fĕr'ri phôs'phās)

"A powder containing not less than 47 per cent. of hydrous ferrous phosphate, $\text{Fe}_2(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$, with ferric phosphate and some iron oxide." *Br.*

Phosphate of Iron; Phosphas Ferroso-Ferricus; Ferroso-Ferric Phosphate; Phosphate de Fer, Phosphate Ferroso-ferrique, *Fr.*; Ferrum Phosphoricum, *P. G.*; Phosphorsäures Eisenoxydul (Eisenoxydul-Oxyd), *G.*; Fosfata de hierro, *Sp.*

"Ferrous Sulphate, 3 ounces (Imperial) or 60 grammes; Sodium Phosphate, 2½ ounces (Imp.) or 55 grammes; Sodium Bicarbonate, 2 ounce (Imp.) or 15 grammes; Distilled Water, boiling, a sufficient quantity. Dissolve the Ferrous Sulphate in thirty fluid ounces (Imp. meas.) or six hundred cubic centimetres of the Distilled Water, and the Sodium Phosphate in an equal quantity of Distilled Water; when each of the solutions has cooled to between 100° and 130° F. (37.8° and 54.4° C.), add the latter to the former, pouring in also a solution of the Sodium Bicarbonate in a little Distilled Water; mix thoroughly; transfer the precipitate to a calico filter; wash it with hot Distilled Water until the washings no longer afford any reaction with the tests for sulphates; finally dry the precipitate at a temperature not exceeding 120° F. (48.9° C.)." *Br.*

This iron phosphate, which is a slate colored powder, must not be confounded with the soluble ferrie phosphate of the *U. S. P.* (8th Rev.), which is in green transparent scales. As obtained by the present process, this *U. S.* preparation is not a definite chemical compound, but a mixture, which should probably be called sodio-ferric citro-phosphate, and bears a resemblance to the pyrophosphate, which is now usually made by a similar process. (See *Ferri Phosphas Solubilis*.)

The British iron phosphate is a very different salt. By double decomposition ferrous phosphate and sodium sulphate are produced, the former precipitating as a white bulky powder, which soon changes on exposure to a greenish-blue, and ultimately to a slate color; since the sodium phosphate is chemically an acid salt (Na_2HPO_4) a portion of phosphoric acid is liberated during the reaction, and this, retaining in solution some of the ferrous phosphate, requires the addition of the solution of sodium bicarbonate to neutralize it and set free the remainder of the ferrous phosphate. This salt, when first formed, is represented by the formula $\text{Fe}_2(\text{PO}_4)_2$; but its strong affinity for oxygen causes the gradual production of sesquisalt, which, therefore, to a certain extent, always exists in the preparation; hence the British authority requires it to contain at least 47 per cent. of ferrous phosphate, $\text{Fe}_2(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$. (See *P. J.*, 1897, 141.)

Properties.—"A slate-blue amorphous powder, insoluble in water, soluble in hydrochloric

acid. The solution yields a precipitate with solutions of potassium ferrocyanide and ferricyanide; and when treated with tartaric acid and an excess of solution of ammonia, and subsequently with the solution of magnesium ammonio-sulphate, it gives a white granular precipitate. Each gramme dissolved in hydrochloric acid should not cease to yield a blue precipitate with solution of potassium ferricyanide until at least 28.2 cubic centimetres of the volumetric solution of potassium bichromate have been added. It should yield no characteristic reaction with the tests for arsenium." *Br.* This shows the presence of 47 per cent. of ferrous phosphate.

Ferric phosphate, dissolved to saturation in a boiling solution of metaphosphoric acid (HP O₃), under the name of *superphosphate of iron*, was proposed as a remedy, in 1851, by Routh of London. Thomas Greenish of the same city, states that the solution of the salt, on cooling, hardens into a mass of pilular consistence, soluble in water in all proportions, and free from any disagreeable or inky taste.

Uses.—Ferric phosphate possesses the general properties of the ferruginous preparations, and has been given with advantage in *amenorrhœa* and *dyspepsia*.

Dose, from five to ten grains (0.32 to 0.65 Gm.).¹

¹ *Compound Syrup of Phosphate of Iron. Chemical Food.*—For a formula for a compound syrup of phosphate of iron by Wiegand, made by introducing into it the phosphates of calcium, potassium, and sodium, and for remarks on the pharmacy of the phosphates by Procter, see *A. J. P.*, 1854 (pp. 111 and 112). A formula similar to Wiegand's, communicated by Edward Parrish as probably representing the process for a secret preparation considerably used in Philadelphia may be found in *A. J. P.*, 1857 (p. 573). These formulas are too complicated to have any therapeutic value. Nevertheless, as the preparations have had much vogue, under the name of *chemical food*, we give the formula of Parrish from the journal referred to. "Take of Sulphate of Iron 600 gr.; Phosphate of Soda 720 gr.; Phosphate of Lime 720 gr.; Glacial Phosphoric Acid 1200 gr.; Carbonate of Soda 40 gr.; Carbonate of Potassa 60 gr.; Hydrochloric Acid, Water of Ammonia, each a sufficient quantity; Powdered Cochineal 120 gr.; Water a sufficient quantity, to make 20 fluidounces; Sugar 36 troyounces; Oil of Orange 10 minims. Dissolve the Sulphate of Iron in 2 fluidounces and the Phosphate of Soda in 4 fluidounces of boiling Water. Mix the solutions, and wash the precipitated phosphate of iron till the washings are tasteless. Dissolve the Phosphate of Lime in 4 fluidounces of boiling Water with sufficient Hydrochloric Acid to make a clear solution, precipitate it with Water of Ammonia, and wash the precipitate. To the freshly precipitated phosphates add the Phosphoric Acid previously dissolved in Water. When clear, add the Carbonates of Soda and Potassa, and afterwards sufficient Hydrochloric Acid to dissolve the precipitate. Now add Cochineal mixed with the Sugar, apply heat, and, when the syrup is formed, strain and flavor it. Each teaspoonful contains about one grain of phosphate of iron and two and a half grains of phosphate of lime, with smaller quantities of the alkaline phosphates, all in perfect solution." The objection to such preparations as this is not that each of the ingredients may not be useful, but that they are so numerous that a morbid state of system in which they can all be indicated must be extremely rare, and every medicine is more or less noxious if given when it is not needed. The probability is that the therapeutic value of the preparation depends mainly on its ferruginous ingredient, and that, as a rule, its therapeutic effects may be equally well if not better obtained from a simple syrup of ferric phosphate. (See *P. J.*, 1893, 795, 797.)

FERRI PHOSPHAS SOLUBILIS. U. S.

SOLUBLE FERRIC PHOSPHATE

(fēr'ri phôs'phās sô-lû'bî-lîs)

"It should contain Ferric Phosphate corresponding in amount to not less than 12 per cent. of metallic iron, and should be kept in amber-colored, well-stoppered bottles, protected from light." *U. S.*

Ferri et Sodii Citro-phosphas; Ferrum Phosphoricum cum Natrio Citrico; Soluble Phosphate of Iron, Sodio-ferric Citro-phosphate; Citro-phosphate de Fer et de Soude, *Fr.*; Natriumferricitro-phosphat, *G.*

No process is given for this preparation in the *U. S. P.* (8th Rev.). That of the *U. S. P.* 1890 is as follows: "Ferric Citrate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Phosphate, uneffloresced, *fifty-five grammes* [or 1 ounce av., 411 grains]; Distilled Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Dissolve the Ferric Citrate in the Distilled Water by heating on a water-bath. To this solution add the Sodium Phosphate, and stir constantly until it is dissolved. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles." *U. S.* 1890. (See preceding article.)

W. A. Puckner (*Proc. A. Ph. A.*, 1897, 231) proposes the following process, preferring potassium chlorate to nitric acid as an oxidizing agent.

Ferrous sulphate, in clear crystals, 156 Gm.; sulphuric acid, 20 Cc.; potassium chlorate, 12 Gm.; ammonia water, 340 Cc.; citric acid, 120 Gm.; sodium phosphate, uneffloresced, 200 Gm.; water, a sufficient quantity. Add the sulphuric acid to 240 Cc. of water, contained in a glass or porcelain vessel, to this add the ferrous sulphate, warm gently until all is dissolved, then add the potassium chlorate and continue the heat for one-half hour, or until a drop of the solution added to potassium ferricyanide test solution no longer produces a distinct green or bluish-green color. Add this solution, slowly and with constant agitation, to the ammonia water contained in a suitable vessel; to this mixture add hot water, 4000 Cc., and allow to subside, and, after one-half hour, decant or siphon off the clear supernatant liquid. To the residue add 2000 Cc. of hot water, allow to subside, and decant; repeat this washing with six portions of hot water, allowing the last portion to subside for at least six hours or overnight. Decant or siphon off the clear liquid as closely as possible, then add to the remaining magma the citric acid and the sodium phosphate, warm gently until solution results, and then evaporate on a water bath at a temperature not exceeding 60° C. until the solution

weighs 500 Gm., and spread it on plates of glass, so that, when dry, the salt may be obtained in scales.

Solution of Ferric Phosphate (50 per cent.). By evaporating the solution made by Puckner's method (see above) on a water bath until it measures 500 Cc., a solution is made containing 50 per cent. of ferric phosphate.

Properties.—It is officially described as in "thin, bright green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air when excluded from light, but when unprotected, soon becomes dark and discolored. Freely and completely soluble in water; insoluble in alcohol. The aqueous solution of the salt shows a slightly acid reaction with blue litmus paper. The addition of ammonia water to the solution of the salt produces a reddish-brown color. If Soluble Ferric Phosphate be boiled with potassium hydroxide T.S., it affords a brownish-red precipitate without evolving ammonia. Dissolve 0.1 Gm. of the salt in 2 Cc. of warm water, add 5 Cc. of potassium hydroxide T.S., boil and filter. Neutralize the filtrate with hydrochloric acid, add 2 Cc. of magnesia mixture T.S. and ammonia water in slight excess. A white, crystalline precipitate is produced, which, if well washed on a filter, is turned yellow by silver nitrate T.S. To 1 Gm. of the salt dissolved in 10 Cc. of water, add 15 Cc. or a slight excess of boiling potassium hydroxide T.S., and, after thoroughly mixing, filter. The filtrate, after strongly acidulating with hydrochloric acid and adding 10 Cc. of magnesia mixture T.S., followed by a slight excess of ammonia water, will afford an abundant, white, crystalline precipitate. If 0.555 Gm. of the salt be dissolved in 10 Cc. of water, in a glass-stoppered flask having a capacity of about 100 Cc., and 2 Cc. of hydrochloric acid and 40 Cc. of water added, and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 12 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid (each Cc. of tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." U. S.

Uses.—See *Ferri Pyrophosphas Solubilis*.

Off. Prep.—Elixir Ferri, Quininae et Strychninae Phosphatum, U. S.; Glyceritum Ferri, Quininae et Strychninae Phosphatum, U. S.; Syrupus Ferri, Quininae et Strychninae Phosphatum, U. S. (from glycerite).

FERRI PYROPHOSPHAS SOLUBILIS.

U. S.

SOLUBLE FERRIC PYROPHOSPHATE

(fēr'ri.py-rō-phōs'phās sō-lū'b'līs)

"It should contain Ferric Pyrophosphate corresponding in amount to not less than 10 per-

cent. of metallic iron, and should be kept in amber-colored, well-stoppered bottles, protected from light." U. S.

Ferri Pyrophosphas, U. S. 1880; Ferric Pyrophosphate; Pyrophosphate of Iron; Ferri et Sodii Citro-pyrophosphas; Ferrum Pyrophosphoricum cum Sodio Citrico; Pyrophosphate of Iron with Sodium Citrate; Sodio-ferric Citro-pyrophosphate; Pyrophosphate de Fer et de Soude, *Fr.*; Pyrophosphorsaures Eisenoxyd mit Citronensaurem Natron, *G.*

"Ferric Citrate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Pyrophosphate, uneffloresced, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Dissolve the Ferric Citrate in the Distilled Water, by heating on a water-bath. To this solution add the Sodium Pyrophosphate, and stir constantly, until it is dissolved. Evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles." U. S. 1890.

There does not seem to be a good reason for appending "Solubilis" to the title of this salt; it is practically the same ferric pyrophosphate as that of the U. S. P. 1880, which had no such addition (see *Ferri Phosphas Solubilis*). The unnecessary lengthening of the official Latin names which must be used in prescription writing is to be strongly deprecated. This formula is based upon a method proposed by M. E. Robiquet to the Academy of Medicine at Paris, in February, 1857, of preparing ferric pyrophosphate for use, by dissolving a gelatinous precipitate of the salt in a solution of ammonium citrate, and forming a syrup with the solution.

The view which obtained when this process was first made official was that a double salt was formed, consisting of ferric pyrophosphate and ammonium citrate, which might be called ammonio-ferric citro-orthophosphate. According to R. Rother (*A. J. P.*, 1876, p. 174), there was an excess of ferric citrate in the pyrophosphate of iron of the U. S. P. 1870, and it was believed to be a complex mixture of the colloid salts ammonio-ferric pyrophosphate, ammonio-ferric citrate, and free ferric citrate, as shown in the reaction:

By mixing two molecules of ferric citrate and one of ammonium pyrophosphate a compound analogous to the official preparation was obtained, containing the same proportion of ammonio-ferric pyrophosphate, but mixed with twice as much ammonio-ferric citrate and free ferric citrate. Rother's views were adopted by the Committee of Revision of 1880, as well as the salt which he recommended, in which ammonia was replaced by soda, because of the greater stability of the latter. Soluble Ferric Pyro-

phosphate consists probably of sodio-ferric pyrophosphate, sodio-ferric citrate, and free ferric citrate.

Sodio-ferric pyrophosphate, dried at 100° C., is considered by Flückiger (*Pharm. Chem.*, 2d ed., p. 607, 1888) to have the following composition:

Properties.—It is officially described as in "thin, apple-green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air, when excluded from light, but when unprotected, soon becomes discolored. Freely and completely soluble in water; insoluble in alcohol. The aqueous solution of the salt shows a slightly acid reaction with blue litmus paper. If Soluble Ferric Pyrophosphate be boiled with potassium hydroxide T.S., it affords a brownish-red precipitate without evolving the odor of ammonia. If 0.1 Gm. of the salt be fused with 0.1 Gm. each of potassium nitrate and sodium carbonate, and the residue boiled with 10 Cc. of distilled water and filtered, the filtrate, after being rendered nearly, but not quite neutral with highly diluted nitric acid, should yield a yellow precipitate upon the addition of silver nitrate T.S. If 0.555 Gm. of the salt be dissolved in 10 Cc. of water, in a glass-stoppered flask having a capacity of about 100 Cc., and 2 Cc. of hydrochloric acid and 40 Cc. of water added, and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 10 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." U. S.

Ridenour believed that the presence of orthophosphate in some samples of ferric pyrophosphate is due to the carelessness of the manufacturer and proposed a test for the presence of orthophosphate (*A. J. P.*, 1900, 125).

Uses.—It is a very good chalybeate, mild yet efficient in its action on the system, without disagreeable taste, and, from its solubility, readily administered in any form that may be desirable, whether that of pill, simple solution in water,¹ or syrup.

Dose, two to ten grains (0.13 to 0.65 Gm.).

FERRI SULPHAS. U. S., Br.

FERROUS SULPHATE [Iron Protosulphate]

(fēr'ri sūl'phās)

"It should contain not less than 99.5 percent. of pure Ferrous Sulphate [$\text{SO}_4.\text{O}_2\text{Fe} +$

$7\text{H}_2\text{O}$]; the crystals should not be effloresced, and should be kept in well-stoppered bottles." U. S. "Ferrous Sulphate, $\text{FeSO}_4.7\text{H}_2\text{O}$, may be prepared by the interaction of diluted sulphuric acid and iron." Br.

Sulphate of Iron, Green Vitriol; Sulfas Ferrosus, Ferrum Vitriolatum Purum, Vitriolum Martis Purum; Sulfate Ferreux Officiel, *Fr. Cod.*; Sulfate (protosulfate) de Fer, *Fr.*; Ferrum Sulfuricum, *P. G.*; Ferrosulfat, Schwefelsaures Eisenoxydul, *G.*; Solfato ferroso, *It.*; Sulfato ferroso, *Sp.*

The British Pharmacopœia (1885) contained the following process for this salt:

"Take of Iron Wire *four ounces* [avoirdupois]; Sulphuric Acid *four fluidounces* [Imperial measure]; Distilled Water *one pint and a half* [Imp. meas.]. Pour the water on the Iron placed in a porcelain dish, add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filtering paper placed on porous bricks, and preserved in a stoppered bottle." Br. 1885.

The object of this process is to make a pure ferrous sulphate by direct combination. Sulphuric acid, in a concentrated state, acts but imperfectly on iron, but when diluted, a vigorous action takes place. The theoretical quantities for mutual reaction are 56 of iron to 98 of acid. This proportion is one part of iron to one and three-quarters of acid. The British Council uses an excess of acid, the weight of acid being 7.38 avoirdupois ounces, instead of 7. An excess of iron, however, is desirable, as it tends to secure the production of a perfect ferrous sulphate. A process for this salt was given in the U. S. P. 1870, which was based upon the method of Bonsdorff. This chemist found that, when a perfect ferrous sulphate was formed in solution by heating diluted sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid were added to the liquid before filtration, in order to prevent the formation of any sesquioxide during the process, at the same time avoiding, as much as possible, contact with the air. Hence the directions in the former U. S. Pharmacopœia formula to acidulate with sulphuric acid, to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air, and to cover the vessel containing the concentrated liquid when it is set aside to crystallize.

Commercial Ferrous Sulphate or Copperas is manufactured on a large scale for the purposes of the arts, from the native ferric sulphide or iron pyrites, by roasting, oxidation by exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and ferrous and ferric oxides, which, by their union, form the salt. Ferrous sulphate is also obtained in many chemical processes as a collateral product, as in the manu-

¹ *Liquor Ferri Pyrophosphatis.*—A permanent solution may be made by Rother's process by dissolving 120 grains of iron pyrophosphate in five fluidrachms of water with the aid of heat, filtering while hot, mixing the filtrate with two fluidrachms of glycerin, and adding enough water through the filter to make one fluidounce. (*D. C.*, 1886, p. 99.)

facture of alum, in the precipitation of copper from solutions of copper sulphate by scraps of iron, etc.

Commercial ferrous sulphate is far from being pure. Besides containing some ferric sulphate, it is generally contaminated with metallic and earthy salts, such as those of copper, zinc, aluminum, and magnesium. Two principal kinds occur in the market, one in large grass-green crystals, the surface of which is studded with ochreous spots; the other of a bluish-green color, and ordinarily mixed with the powder of the effloresced salt. Commercial sulphate should never be dispensed by the pharmacist until it has undergone purification by recrystallization from a slightly acid solution.

Properties.—Ferrous sulphate is in the form of "large, pale bluish-green, monoclinic prisms, without odor, and having a saline, styptic taste; efflorescent in dry air. On exposure to moist air, the crystals rapidly oxidize, and become coated with brownish-yellow, basic ferric sulphate. Soluble in 0.9 part of water at 25° C. (77° F.) and in 0.3 part of boiling water; insoluble in alcohol. When slowly heated to 115° C. (239° F.), the crystals disintegrate, and lose 38.87 percent. of their weight (6 molecules of water of crystallization). The aqueous solution of the salt shows an acid reaction with blue litmus paper, and, even when highly diluted, gives with potassium ferricyanide T.S. a blue color or precipitate, and with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. If 1 Gm. of the salt be dissolved in about 25 Cc. of water, containing 1 Cc. of diluted sulphuric acid, the solution heated to boiling, oxidized with nitric acid, and then mixed with a slight excess of ammonia water, the filtrate from the reddish-brown precipitate produced should be colorless, and, after acidulating with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If another portion of the salt be oxidized and precipitated as directed above, the filtrate, on evaporation to dryness and ignition, should not leave any weighable residue (absence of salts of the *alkali metals*). If 1 Gm. of Ferrous Sulphate, in small fragments, be agitated during four or five minutes with 10 Cc. of alcohol, the filtrate should not redden moistened blue litmus paper (absence of *free acid*). If 1.38 Gm. of the salt, in uneffloresced crystals, be dissolved in about 25 Cc. of diluted sulphuric acid, not less than 49.75 Cc. of tenth-normal potassium permanganate V.S. should be required to impart to the liquid a permanent pink color (each Cc. of the tenth-normal potassium permanganate V.S. indicating 2 percent. of crystallized Ferrous Sulphate)." *U. S.* "In oblique rhombic prisms, of a pale bluish-green color and astringent taste; insoluble in *alcohol* (90 per cent.), soluble in less than 2 parts of cold *water* and giving a clear solution (absence of oxy-sulphate). It affords the reactions characteristic of ferrous salts and of sulphates.

Each gramme dissolved in *water* acidulated with *sulphuric acid* should not cease to yield a blue precipitate with *solution of potassium ferricyanide* until 36 cubic centimetres of the *volume-metric solution of potassium bichromate* have been added. It should yield no characteristic reaction with the tests for copper, zinc, potassium, sodium, or ammonium. Its solution in *water* should not give any precipitate with *hydrogen sulphide* (absence of ferric compounds, etc.)." *Br.* As prepared by Bonsdorff's method, ferrous sulphate is blue, verging upon green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. By exposure to the air the crystals absorb oxygen, and become first green, and ultimately covered with a yellow efflorescence of subsulphate, insoluble in *water*. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. The aqueous solution is bluish green, but by standing it attracts oxygen, and becomes first green and then reddish, depositing, in the meantime, a portion of sesquisulphate, having the composition:

At a red heat it loses its acid, and is converted into the anhydrous ferric oxide called *colcothar*. It is incompatible with the alkalies and their carbonates, soaps, lime water, calcium and barium chlorides, sodium borate and phosphate, silver nitrate, and lead acetate and subacetate. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesquioxide be present, a black compound of the nature of ink. The extent to which this change lessens the activity of the salt is not well ascertained. Ferrous sulphate, as found in commerce, is often the impure commercial sulphate, which is not fit for medicinal use. The perfectly pure salt is precipitated white by potassium ferrocyanide, but that of ordinary purity gives a greenish precipitate, more or less deep, with this test, owing to the presence of some ferric oxide. Copper may be detected by immersing in the solution a bright piece of iron, on which a cuprous film will be deposited. Both copper and zinc may be discovered by oxidizing the iron by boiling the solution of the salt with nitric acid and then precipitating the iron by an excess of ammonia. If the filtered solution be blue, copper is present, and if it contain zinc, this will be separated in flakes of white oxide on expelling the excess of ammonia by ebullition.

It is often desirable to protect ferrous sulphate against the oxidation to which it is liable on exposure. Sugar acts as a preservative in the case of this salt, as in that of ferrous iodide. It may be added to the solution, or incorporated with the sulphate in substance. E. Latour has given a formula for crystallizing the salt with sugar. Geo. Welborn has found that a small lump of camphor, wrapped in tissue

paper, and placed in the bottle with the sulphate, prevents its oxidation. (P. J., May, 1868, p. 537.) Pavesi of Mortara, effects the same object by incorporating it with an equal weight of gum arabic, by evaporating a joint solution of the two substances with a gentle heat. (J. P. C., 4e sér., iii. 49.)

Uses.—Ferrous sulphate is a very astringent chalybeate. In overdoses it produces nausea, vomiting, griping, and purging, and other evidences of gastro-enteric irritation or inflammation. Its astringency fits it especially for use when anæmia is conjoined with marked relaxation or a tendency to immoderate discharges, such as *passive hemorrhages*, *colligative sweats*, *leucorrhæa*, *gleet*, etc. Externally, the solution has been used in chronic *ophthalmia*, *leucorrhæa*, and *gleet*, made of various strengths, from one or two to eight or ten grains of the salt to the fluidounce of water. Velpeau has found it an excellent remedy in *erysipelas*, applied topically in the form of solution or ointment. The solution was made of three and a half drachms of the salt to a pint of water, and applied by compresses kept constantly wet. In a few cases convenience required the application of the ointment, made of eight parts of the salt to thirty of lard. An ointment made of one or two parts of the sulphate to sixty of lard was found by Devergie to be particularly efficacious in certain skin diseases, especially in *eczema*. In scaly affections it had no effect. (See *Ferri Sulphas Exsiccatus*.)

Ferrous sulphate, usually in the form of the impure salt or commercial copperas, is a feeble disinfectant. When thrown into a mass of decomposing organic matter, a portion of it is at once precipitated as a sulphide or as an oxide by the hydrogen sulphide and ammonia present. It is asserted that ferric sulphate unites with organic substances to form definite stable compounds, and that animal substances kept in a 3 per cent. solution of neutral ferric sulphate for some time and then removed, mummify without decomposition. (N. R., Dec. 1883, 685.)

Dose, two to five grains (0.13 to 0.32 Gm.).

FERRI SULPHAS EXSICCATUS. U. S., Br.

EXSICCATED FERROUS SULPHATE [Dried Ferrous Sulphate]

(fēr'ri sŭl'phās ěx-sĭc-că'tŭs)

Approximately $3\text{FeSO}_4 \cdot 2\text{H}_2\text{O} = 488.31$

Ferri Sulphas Exsiccata, Br. 1885; Dried Sulphate of Iron; Sulfate Ferreux desséché, Fr.; Ferrum Sulfuricum Siccum, P. G.; Getrocknetes Ferrosulfat, Entwässertes Schwefelsaures Eisenoxydul, G.; Sulfato ferroso desecado, Sp.

(33)

* "Ferrous Sulphate, in coarse powder, one hundred grammes [or 3 ounces av., 231 grains]. Allow the salt to effloresce at a temperature of about 40° C. (104° F.), in dry air, and then heat it in a porcelain dish, on a water-bath, constantly stirring, until the product weighs from sixty-four to sixty-five grammes [or 2 ounces av., 113 grains to 2 ounces av., 128 grains]. Lastly, reduce the residue to a fine powder, and transfer it at once to perfectly dry, well-stoppered bottles." U. S.

"Expose Ferrous Sulphate, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, in a porcelain or iron dish to a temperature of 212° F. (100° C.), stirring occasionally until aqueous vapor ceases to be given off; reduce the residue, which should weigh about 60 per cent. of the original salt, to a fine powder." Br.

Properties.—"A grayish-white powder, slowly but completely soluble in water, and conforming to the reactions and tests given under *Ferri Sulphas*." U. S. 100 parts of crystallized ferrous sulphate yield about 65 parts of the exsiccated salt. "A nearly white powder, slowly but entirely soluble in water. Each gramme dissolved in water acidulated with sulphuric acid should not cease to yield a blue precipitate with solution of potassium ferricyanide until at least 54.6 cubic centimetres of the volumetric solution of potassium bichromate have been added, corresponding to at least 92½ per cent. of Exsiccated Ferrous Sulphate, $\text{FeSO}_4 \cdot \text{H}_2\text{O}$." Br.

In this process about six molecules out of seven, of the water of crystallization of the salt, are driven off. The heat should not exceed 149° C. (300° F.), otherwise the salt itself would suffer decomposition. If the heat has been excessive, the color of the salt will be brownish instead of grayish white. Dried ferrous sulphate is used for making pills, the crystallized sulphate not being adapted to that purpose. In prescribing the dried sulphate it is necessary to recollect that about three grains of it are equivalent to five grains of the crystallized salt.

Dose, one to three grains (0.065 to 0.2 Gm.).

FERRI SULPHAS GRANULATUS. U. S.

GRANULATED FERROUS SULPHATE [Precipitated Ferrous Sulphate]

(fēr'ri sŭl'phās grăn-ŭ-lă'tŭs)

Granulated Sulphate of Iron; Ferri Sulphas Præcipitatus, U. S. P. 1880; Precipitated Sulphate of Iron; Sulfate Ferreux précipité, Fr.; Præcipitirtes Ferrosulfat, G.

* "Ferrous Sulphate, one hundred grammes [or 3 ounces av., 231 grains]; Distilled Water, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Diluted Sulphuric Acid, five cubic centimeters [or 81 minims]; Alcohol, twenty-five cubic centimeters [or 406 minims].

Dissolve the Ferrous Sulphate in the Distilled Water previously heated to boiling, add the Diluted Sulphuric Acid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain dish, on a sand-bath, until it weighs *one hundred and fifty grammes* [or 5 ounces av., 127 grains], and then cool it quickly, with constant stirring. Transfer the product to a glass funnel stopped with a plug of purified cotton, and, when it has thoroughly drained, pour upon it the Alcohol. When this has also drained, spread the crystalline powder on bibulous paper, dry it quickly at the ordinary temperature, and transfer it at once to perfectly dry, well-stoppered bottles." *U. S.*

The process of the U. S. P. (1890), retained by the U. S. P. (8th Rev.), differs radically in manipulation from that of 1880; instead of pouring the filtered solution of ferrous sulphate into alcohol and collecting the precipitate which falls, the solution is granulated by heat with constant stirring (not quite to dryness), and this salt is then washed with alcohol, which displaces impurities and facilitates the rapid drying of the granular powder.

The product is practically identical with the granulated sulphate of iron of the British Pharmacopœia (1885). The British Pharmacopœia (1898) omitted the granulated salt entirely. The process of the U. S. Pharmacopœia of 1880 had the advantage of being more manageable and convenient, ferrous sulphate being used directly instead of being made by the action of sulphuric acid on the metal. The directions given in the first part of the former British process are precisely the same as those laid down by the British Council for making ferrous sulphate; but the hot solution of the iron in the sulphuric acid, instead of being allowed to filter into an empty vessel, is made to drop into a portion of rectified spirit, the mixture being stirred while it cools. The acid directed is in excess, and the filtrate is consequently an acid solution of ferrous sulphate mixed with spirit. The stirring as the mixture cools, finely granulates the salt, which separates perfectly pure, the spirit holding in solution any ferric sulphate which may have been formed, and the excess of acid dissolving any free sesquioxide. This process, in its main features, is that of Berthemet. (See 8th ed., U. S. D.)

Properties.—"Granulated Ferrous Sulphate is a very pale bluish-green, crystalline powder, which should conform in every respect to the reactions and tests given under *Ferri Sulphas*." *U. S.* Barchhauser, Salzer, and others have stated that ferrous sulphate precipitated by alcohol did not always contain seven molecules of water, and it could not be relied upon for making volumetric solutions because of this lack of uniformity in composition. Caro (*Ann. Ch. Ph.*, clxv. 29) and Schliekum (*Ph. Ztg.*, No. 49), on the other hand, maintain that precipitated ferrous sulphate is constant in composition, and Schliekum proved that if the precipitation took place in the cold it always con-

tained seven molecules of water, but *boiling* with strong alcohol diminished the proportion of water of crystallization. This salt is less liable to oxidation on exposure than is the sulphate in its ordinary form, and experience has shown that it is admirably adapted for dispensing.

Dose, two to five grains (0.13 to 0.32 Gm.).

FERRUM. U. S., Br.

IRON

(fĕr'rūm)

Fe=55.5

"Metallic iron, in the form of fine, bright, and non-elastic wire." *U. S.* "Annealed iron wire, having a diameter of about 0.005 inch (0.1 millimetre) (about No. 35 wire gauge), or wrought-iron nails, free from oxide." *Br.*

Fer, Mars, Fer métallique, *Fr. Cod.*; Fil de Fer, *Fr.*; Eisen, Eisendraht, *G.*; Ferro, Limatura di ferro, *It.*; Hierro, *Sp.*

In the U. S. Pharmacopœia, this metal is employed in different preparations in the form of wire; it was official in 1850 as *Ferri Rammenta*, *Iron Filings*.¹

Iron is the most abundant and useful of the metals, and so interwoven with the wants of mankind that the extent of its consumption by a nation may be taken as an index of progress in civilization. It is universally diffused in nature, not only in the mineral but also in the vegetable and animal kingdoms. There are very few minerals in which traces of it are not to be found, and it is an essential constituent in many parts of animals, but particularly in the blood. It is one of the few metals which are not deleterious to the animal economy. Iron occurs: 1, native (almost exclusively, however, of meteoric origin); 2, sulphuretted, in the minerals *pyrites* (simple ferric

Iron Filings.—*Ferri Ramenta*, U. S. 1850. Limatura Ferri; Limailles de Fer, *Fr.*; Eisenfeilicht, *G.*; Limatura di ferro, *It.*; Limatura de hierro, *Sp.* Iron, when employed in pharmaceutical operations, should be of the purest kind; and hence the Pharmacopœias generally direct it, when wanted in small masses, to be in the form of *iron wire*, which is necessarily made from the purest, because the softest and most ductile iron, and is readily cut into pieces. The wire is very flexible and without elasticity.

Iron filings are usually obtained from the workshops of the blacksmith; but, as furnished from this source, they are generally very impure, and unfit for medicinal use. Gobeley, upon examining thirty-six samples of iron filings, found but three exempt from copper; the rest, besides wood, sand, and ferric oxide, contained as high as 2 per cent. of this metal. Iron filings cannot be completely purified by the magnet, as they often have adhering to them bits of foreign matter which are carried up with them. The only way to obtain them pure is to file a piece of pure iron with a clean file. The French Codex directs iron in an *impalpable powder* prepared by porphyzizing bright and clean iron filings without water. A dull black powder is formed, which must be carefully preserved from moisture. An impalpable powder of the metal, *Ferrum Reductum*, is official.

sulphide), *pyrrhotine*, or *magnetic pyrites*, and *arsenopyrite* or *mispickel* (a sulph-arsenide of iron); 3, oxidized, embracing the magnetic, specular, red, brown, and argillaceous iron oxides, also *chromite* (mixed iron, chromium, and magnesium oxides) and *franklinite* (mixed iron, manganese, and zinc oxides); 4, in saline combination, forming ferrous carbonate, sulphate, phosphate, and arsenate. Those minerals of iron which admit of being worked to advantage are called *iron ores*. These include the different native oxides, and the carbonate (spathic iron). The best iron is obtained from the ferroso-ferric oxide, usually called magnetic iron ore, and the anhydrous sesquioxide, known as specular iron ore. These occur abundantly in Sweden, and furnish the superior iron of that country. The upper peninsula of Michigan and the borders of Lake Champlain in New York yield similar ores. As a rule, those ores yield the best iron which occur in primitive formations.

Extraction.—The mode of extracting iron from its ores varies somewhat with the nature of the ore; but the general principles of the operation are the same for all. The ore, previously broken into small pieces and roasted, is exposed to the action of an intense heat, urged by an air blast, in contact with carbonaceous matter, such as charcoal, coke, or anthracite, and in connection with some flux capable of fusing with the impurities of the ore. The flux varies with the nature of the ore, and is generally limestone. Fluorspar is occasionally used, but is not often found in sufficiently large deposits to be available. The flux, whatever it may be, enters into fusion with the impurities, and forms what is called the slag, which is a fusible lime silicate chiefly, while the carbon monoxide formed from the carbonaceous matter, acting on the ferric oxide, reduces it to the metallic state. The reduced metal, from its density, occupies the lower part of the furnace, and is protected from the action of the air by the melted slag which floats on its surface. When the reduction is completed, the slag is allowed to run out by a hole in the side of the furnace, and the melted metal by an aperture at the bottom, the latter being received into a series of sand moulds, where it solidifies in masses, known in commerce by the name of *pig* or *cast iron*. In this state the metal is brittle and far from being pure, as it contains from 3 to 6 per cent. of carbon, with silicon, phosphorus, sulphur, and manganese. It is purified, and brought to the state of *malleable iron*, by being fused and subjected, while stirred, to the action of a current of air on its surface. By these means the carbon is nearly burnt out, and the other impurities are oxidized and made to rise to the surface as a slag. Instead of this process, called "refining," usage in this country and in England substitutes what is called "pig boiling,"—that is, the pig iron is at once submitted to the operation of puddling without previous

refining. The "puddling" process consists in heating the charge of pig iron on the hearth of a reverberatory furnace in contact with ferric oxide and in a reducing flame. The silicon is first burnt out, and then the carbon gradually disappears; the phosphorus goes into the "tap cinder" as phosphide and phosphate; the sulphur in part disappears as sulphur dioxide and in part remains in the cinder as ferrous sulphide. As the metal approaches to purity, it becomes tough and less liquid, and its particles agglutinate so as to form semi-fused lumps, though the temperature of the furnace continues the same. These lumps are then taken out of the furnace, and their particles, by means of ponderous hammers moved by steam or water power, or by great pressure, are forced together so as to form one tenacious mass. The metal is finally rolled out into bars of a convenient size, when it constitutes the malleable iron of commerce.

The third form of commercial iron, known as "steel," is made either by the *cementation* process, the *Bessemer* process, or the *open hearth* process. In the first case, wrought iron is packed with charcoal and heated until combination takes place, and the resulting steel is cast into ingots. In the second case, cast iron is melted in large vessels called converters, when a blast of air is blown through the mass, burning out the requisite amount of carbon, and then, after addition of a small amount of *spiegeleisen*, or manganeseiferous cast iron, the finished product is run into moulds; while in the third or open hearth process, a mixture of pig iron and ore is heated with a reverberatory flame, as in the puddling process, or bars and blooms of wrought iron are heated with the pig iron, and steel is made by the combination of the two. Steel contains from $\frac{1}{2}$ to 1 per cent. of carbon.

The production of pig iron in the United States in 1905 was 22,992,380 tons, valued at \$379,374,270. The steel production of the United States for 1905, was Bessemer steel, 10,941,375 tons; open hearth steel, 8,971,376 tons; crucible and miscellaneous, 121,000 tons, a total of all kinds of steel, of 20,033,751 tons.

The United States, in 1905, produced 43.2 per cent. of the pig iron of the world, and 46.5 per cent. of the steel, Germany coming second, and Great Britain third, in each case. There was a shrinkage in the production of both iron and steel in the United States in 1904, but in 1905 the production again increased.

Iron mines occur in most countries, but more particularly in northern ones. In Spain the principal mines furnish spathic iron and the red oxide. The chief iron ores of France are the spathic iron, and the specular, brown, and argillaceous oxides; of Germany, the spathic iron and brown oxide. The island of Elba is celebrated for its rich and abundant specular iron ore. In the United States iron is abundant. The principle ores that are worked are the magnetic, red, and brown oxides. The

magnetic oxide is found in large beds in Essex Co., N. Y., on the borders of Lake Champlain, and in the Lake Superior district; the red oxide in New York, New Jersey, Pennsylvania, Alabama, and especially in a very pure state in Missouri, at Iron Mountain and Pilot Knob; the brown oxide in Eastern Pennsylvania.

Properties.—Iron is a hard, malleable, ductile, and tenacious metal, of a grayish-white color and fibrous texture, a characteristic taste, and a sensible odor when rubbed. In tenacity it yields only to nickel and cobalt. (Deville.) Its sp. gr. is about 7.7, and its fusing point very high. It possesses magnetic and welding properties. It is combustible, and, when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen gas. At a red heat, its surface is converted into black oxide, and at common temperatures, by the combined agency of air and moisture, it becomes covered with a yellowish-brown matter, called *rust*, which is the hydrated sesquioxide. It combines with all the non-metallic elements, except hydrogen and nitrogen, and with most of the metals. It forms three compounds with oxygen, a ferrous oxide and a ferric oxide, which by their union form the native magnetic oxide, hence often termed ferrous-ferric oxide, and a trioxide, which forms an acid called ferric acid. The *monoxide*, or ferrous oxide, is of a dark blue color, attracted by the magnet, and spontaneously combustible in the air, being converted into sesquioxide or ferric oxide. It is the base of ferrous sulphate, and the green salts of iron generally. It is very prone to absorb oxygen, and hence the salts which contain it are soon partially converted, when in solution, into salts of the ferric oxide. Its formula is FeO , consisting of one atom of iron, Fe, and one of oxygen, O. The *sesquioxide*, or ferric oxide, is readily obtained by dissolving iron in nitrohydrochloric acid, precipitating by ammonia, and igniting the precipitate. It is of a red color, not attracted by the magnet, and forms salts which for the most part have a reddish color. Its formula is Fe_2O_3 , consisting of two atoms of iron, Fe, and three atoms of oxygen, O. An allotropic variety of the sesquioxide, soluble in water, and not responding to the ordinary tests of iron, has been discovered by Péan de Saint-Gilles. The *native black oxide*, the magnetic oxide of mineralogists, consists of one molecule of FeO and one molecule of Fe_2O_3 .

Under the name of *Ferri Oxidum Magneticum*, the British Pharmacopœia had a preparation consisting of this oxide with three molecules of water. *Ferric acid*, discovered by Fremy, may be obtained, in union with potassium hydroxide, by passing chlorine through a very concentrated solution of the alkali, holding the hydrated ferric oxide in suspension, or by fusing iron filings with potassium nitrate. The acid anhydride consists of one atom of iron and three of oxygen, FeO_3 . Iron forms a number of important salts.

Iron is readily detected, even in minute quantities, by bringing it to the state of ferric salt in solution, and adding potassium ferrocyanide or tincture of galls, the former of which will strike a deep blue, the latter a black color. Bringing it to the state of a ferric salt is readily effected by boiling the solution containing it with a little nitric acid. The testing of the official scaled salts of iron has attracted the attention of chemists, it being well known that these are not definite chemical compounds. F. B. Power prefers the *iodometric method* for estimating the quantity of iron in scaled salts. It is based on the liberation of iodine by a solution of ferric chloride, and the subsequent estimation of the liberated iodine by a tenth-normal volumetric solution of sodium thiosulphate. (*Ph. Rund.*, 1891, 205.)

Uses.—*General Therapeutic Effects of Iron.* Since iron constitutes an integrant portion of the red blood corpuscles, it is a necessity for their production, and the great indication for its use is lack of hæmoglobin in the blood,—i. e., *anæmia*. It is plain that the lack of hæmoglobin may be due to the lessening of the number of the red blood corpuscles, or it may be the outcome of a lack of the normal amount of hæmoglobin in the individual blood corpuscles. The distinction between these two varieties of anæmia is important, since clinical experience has shown that in anæmia of the first of these classes—the so-called "*pernicious anæmias*," in which there is a marked diminution of the number of the red blood corpuscles—the prognosis is very grave, while in *chlorotic anæmias* in which there is simply poverty of hæmoglobin the prognosis is favorable. In essential anæmias iron may be administered, but is of very little value. In the non-essential or simple anæmias the effect of the administration of iron varies with the cause of the anæmia, but is usually more or less favorable. In the so called *accidental anæmias*, in which the poverty of the blood is due to some temporary, removable, or self-disappearing cause, such as hemorrhage, snake or other poisonings that destroy the red blood corpuscles, iron is of great service in hastening the recovery after the immediate activity of the cause has ceased. In *secondary anæmias*, such as those which follow impaired digestion, diarrhœa, abscesses, and various chronic diseases, iron should be exhibited, provided it has no injurious effect upon the disease which is producing the anæmia. In the class of anæmias typified by *chlorosis*, in which the anæmia is part of a subacute disease of obscure nature, iron is often an extraordinarily effective remedy, evidently doing something more than merely supplying material for the making of the red blood corpuscles. By stimulating the organs which produce the red blood corpuscles, or in some other less direct manner, it evidently increases the manufacture of hæmoglobin in the system.

The old belief that iron is a tonic, independent of its influence upon anæmia, is a mis-

take, there being no sufficient reason for supposing that iron has other therapeutic properties than those of astringency and of chalybeate action, except some special preparations, such as the iodide and the chloride, which are peculiar in their influence by virtue of some substance in them other than the iron.

The question of the selection of a preparation of iron for an individual case is often one of great importance. If it be simply desired to combat anæmia, a preparation should be selected which is free as may be from astringency or peculiar property and is suitable to the individual taste of the patient. Most of the liquid preparations of iron are more or less injurious to the teeth, so that commonly it is preferable to give a solid salt in pill or capsule rather than one of the liquid forms, unless the latter be especially indicated.

The question of the capability of iron preparations of being absorbed is one which has called for an amount of chemical investigation which is so great that even to epitomize it would carry us beyond the proper bounds of an article for a dispensatory, we therefore refer our readers to the last edition of H. C. Wood's *Therapeutics*. It is sufficient to note that many chemists have asserted that most, if not all, of the official preparations of iron are practically not absorbed,—a conclusion which is so at variance with an overwhelming amount of clinical evidence that it could not, under any circumstances, be accepted by clinicians; moreover, it is at present opposed by recent chemical researches, which show many fallacies underlying the older work, and seem to prove the correctness of the position which clinicians have steadily held to,—namely, that the human body is capable of absorbing iron from almost all, if not all, of the official iron preparations. Spurred on by the theory that the inorganic salts of iron are not absorbed, pharmaceutical chemists have devised various organic compounds which will be considered in detail in PART II of this book. There is, however, no sufficient reason for believing that these complicated and costly preparations of iron are in any way superior to the older official forms.

It would probably be much better if the U. S. P. recognized only a fraction of the present official preparations. All that can be accomplished with any preparation in simple anæmia can be done with reduced iron or pill of the carbonate for exhibition in solid form and the ammonio-citrate for liquids. No compounds in which iron is combined with an alkaloid should be recognized by the Pharmacopœia or used by the practitioner. Of course such combinations are to a greater or less extent effective, but the proportionate amount of the alkaloid and the iron required in individual cases varies indefinitely, and the habitual use of a fixed proportion, such as is demanded by the pharmacopœial combinations, strongly inclines the practitioner of medicine to careless and routine

practice. The official alkaloidal-ferruginous preparations have no advantage whatever over extemporaneous prescriptions combining iron and the alkaloid.

Certain salts of iron are extremely astringent and more or less irritant. The most important of these are the sulphates and the chlorides. These salts should never be employed as chalybeates, except in those cases in which, for some reason, astringency is desired. Although the mildest of the pure chalybeate preparations are somewhat astringent, and have a tendency to produce constipation, they are also somewhat irritant to the mucous membrane of the gastro-intestinal tract. Such salts as the sulphate or the chloride are very astringent and very irritating. Any functional disarrangement of the digestive organs is a contraindication of greater or less force to the use of iron, and when the loss of functional power depends upon gastric or intestinal catarrh, or upon other organic diseases of the gastro-intestinal mucous membrane, iron is strongly contraindicated. We have often seen great injury done to patients suffering from gastro-intestinal catarrh by the iron given with the hope of relieving the anæmia, which has been secondary to the interference with digestion by the disease. A second contraindication to the use of iron is a rheumatic diathesis, though in rare cases of *chronic rheumatism* in which there is pronounced anæmia iron may do good. In most cases some laxative should be combined with iron to overcome its constipating influence.

Iron has been employed hypodermically to some extent. It has been shown by the chemists working under Kobert of Dorpat, that when a solution of iron and sodium citrate is injected subcutaneously in man, 40 per cent. of the iron escapes in the urine unaltered, the elimination of the iron usually being accompanied by pronounced renal irritation. The hypodermic use of some of the organic compounds of iron has been strongly recommended by investigators. The latest researches seem, however, to show that the iron citrate is as good a preparation for the hypodermic administration of iron as any other, the iron appearing in the urine half an hour after its injection and being present for twenty-four hours. According to Gloevecke, 1 Cc. of a 10 per cent. solution, thrown into the muscles of the back, causes an enduring sharp pain, but Lepine asserts that 2.5 Cc. of a 4 per cent. solution produces little or no disturbance. It is stated that after the hypodermic injection of large doses the irritation of the alimentary canal is more severe than when the drug is given by the mouth,—a statement which finds confirmation in the experiments of Gottlieb, who found that when he injected iron subcutaneously into a dog he was able to obtain nearly 97 per cent. of it from the fæces. The effort at intestinal elimination is evidently accompanied by irritation if the amount of iron to be eliminated is large.

Unsoundness of the kidney is an absolute contraindication to the hypodermic use of iron; hæmaturia and urinary suppression have been produced by the remedy under such circumstances. In ordinary cases of anæmia iron should not be used hypodermically, but when, under the influence of certain poisons, there is very rapid destruction of the hæmoglobin the method may be employed, and trials of it in the essential anæmias are justifiable.

Cod.; Ferrum reductum, P. G.; Reduzirtes Eisen, G.; Ferro ridotto dall' idrogeno, It.; Hierro reducido por el hidrogeno, Sp.*

A process for this form of iron is no longer given in the United States Pharmacopeia.¹

This preparation was introduced into the United States and Dublin Pharmacopœias of 1850, and is retained in the present edition

¹ *Ferrum Redactum.*—"Take of Subcarbonate of Iron thirty troyounces. Wash the Subcarbonate thoroughly with water until no traces of sulphate of sodium are indicated by the appropriate tests, and calcine it in a shallow vessel until free from moisture. Then spread it upon a tray, made by bending an oblong piece of sheet-iron in the form of an incomplete cylinder, and introduce this into a wrought-iron reduction-tube, of about four inches in diameter. Place the reduction-tube in a charcoal furnace; and, by means of a self-regulating generator of hydrogen, pass through it a stream of that gas, previously purified by bubbling successively through solution of subacetate of lead, diluted with three times its volume of water, and through milk of lime, severally contained in four-pint bottles, about one-third filled. Connect with the further extremity of the reduction-tube a lead tube bent so as to dip into water. Make all the junctions air-tight by appropriate lutes; and, when the hydrogen has passed long enough to fill the whole of the apparatus to the exclusion of atmospheric air, light the fire, and bring that part of the reduction-tube, occupied by the Subcarbonate, to a dull-red heat, which must be kept up so long as the bubbles of hydrogen, breaking from the water covering the orifice of the lead tube, are accompanied by visible aqueous vapor. When the reduction is completed, remove the fire, and allow the whole to cool to the ordinary temperature, keeping up, during the refrigeration, a moderate current of hydrogen through the apparatus. Withdraw the product from the reduction-tube, and, should any portion of it be black instead of iron-gray, separate such portion for use in a subsequent operation. Lastly, having powdered the Reduced Iron, keep it in a well-stoppered bottle. When thirty troyounces of Subcarbonate of Iron are operated on, the process occupies from five to eight hours." *U. S. 1870.*

of our own, although the process for it has been abandoned. It consists of metallic iron in fine powder, obtained by reducing the ferric oxide by hydrogen at a dull red heat. The subcarbonate of the U. S. Pharm. 1870, which is essentially the ferric oxide, is deprived of water by calcination, and then subjected to the reducing influence of a stream of hydrogen, purified from hydrogen sulphide and acid compounds by passing successively through a solution of lead subacetate and milk of lime. The hydrogen unites with the oxygen of the ferric oxide to form water, and leaves the iron in the metallic state. The subcarbonate should be perfectly free from sodium sulphate, which it is likely to contain when imperfectly washed. If this salt be present, it will be reduced by the hydrogen to the state of sodium sulphide, which will contaminate and spoil the metallic iron formed, and cause the preparation, when taken, to give rise to unpleasant eructations. The heat should be carefully regulated, for if it fall below dull redness, part of the oxide will escape reduction, and if it exceed that point considerably, the particles of reduced iron will agglutinate, and the preparation will be heavy and not readily pulverizable. The 1885 British process is not so well fitted for practical purposes as is that of the U. S. Pharm. 1870. In the 1885 revision of the British Pharmacopœia, instead of directing a certain quantity of hydrated ferric oxide, a process is given in the formula for making the ferric oxyhydrate by precipitating a solution of ferric chloride. The direction to dry the hydrogen is unnecessary. On the subject of powder of iron, manufacturing chemists will find it useful to consult the paper of Soubeiran and Dublanc, in which full directions are given for purifying the hydrogen, constructing the furnace, regulating the heat, and avoiding explosions. (*A. J. P.*, xviii. 303.) For improvements by Procter, see *A. J. P.*, xix. 11. The necessity for purification of the hydrogen by passing it successively through concentrated potassium permanganate solution, lead acetate solution, and sulphuric acid has been proved by T. Appel. (*Oest. Zeit. f. Pharm.*, 1892, 395.)

Since the tenth edition of this work was published, several processes have been proposed for obtaining powder of iron. Arthur Morgan of Dublin, recommended the use of dried potassium ferrocyanide, thoroughly mixed with anhydrous ferric oxide, and calcined with pure potassium carbonate at a low red heat. The product contains all the iron in a reduced state, mixed with soluble matters, which are carefully washed away. (See *A. J. P.*, 1854, p. 450.) A similar process to the above has been proposed by a German chemist, named Zängerle, iron oxalate being substituted for the ferric oxide. (See *P. J.*, 1857, p. 565.) Wöhler recommended the use of the same oxalate, not in connection with potassium ferrocyanide, but as a suitable compound of iron for reduction by hydrogen. W. Müller found that ferric

oxide obtained by heating the metal in the air is reduced when moist at 293° C. (559.4° F.); when quite dry, at 305° to 339° C. (581° to 642.2° F.); the oxalate moist, at 278° C. (532.4° F.). Another eligible compound for reduction is the crystalline powder of ferric oxide, prepared by fusing, in a clay crucible, pure dried ferrous sulphate with three times its weight of sodium chloride, and then washing the melted mass when cold, until everything soluble is removed. (Wöhler.) Crolas prepares a pure ferric oxide by adding barium chloride to the solution of ferric chloride to precipitate the contaminating sulphate, getting rid of the barium chloride by crystallization and precipitating by solution of ammonia. The ammonium chloride is driven off by heat. (*J. P. C.* 4e sér. xx. 30.) The process of Eugène Fegueux consists in reducing the ferric oxide by carbonic oxide, formed by passing a stream of carbon dioxide over red hot charcoal in the reduction tube, before it reaches the ferric oxide. The carbon dioxide, thus reduced to carbonic oxide, is formed again by the deoxidizing of the ferruginous oxide.

Under the name of "*alcoholized iron*," a powder of iron has been introduced into this country, said to be prepared, in the eastern parts of Germany, by attrition of iron filings with honey, by some cheap method, as by attachment to a saw mill or steam machinery. It has the appearance of powdered plumbago, but under the magnifying glass is seen to contain particles with the metallic lustre and rounded as if by friction. It is soluble in diluted sulphuric acid, with the escape of hydrogen free, or nearly so, from sulphur, but a small quantity of black powder remains undissolved. (*A. J. P.*, 1867, p. 11.) The relation of the epithet "*alcoholized*" to this powder is not very obvious, as this name was given originally to iron obtained by passing alcohol vapor over ferric oxide. It is not much inferior to reduced iron, and is better than some preparations sold by that name.

Properties.—Powder of iron, called by the French *fer réduit*, is a light, tasteless powder, soft to the touch, of an iron-gray color, and without metallic lustre. If black, the preparation is to be rejected as not being fully deoxidized. When thrown into a diluted acid, it causes a lively effervescence of hydrogen without odor. A small portion of it, struck on an anvil with a smooth hammer, forms a scale having a brilliant metallic lustre. It takes fire upon the application of a burning body. On account of its great liability to oxidation, it should be kept in a dry bottle, well stoppered. A black powder, having a composition corresponding with that of the magnetic oxide of iron, has been sold under the name of Quevenne's iron. The spurious powder may be known by its having a black instead of an iron-gray color, and by its effervescing but slightly with acids. In the process for making reduced iron, part of the sesquioxide almost al-

ways escapes full deoxidation, and comes out of the tube having a black color. This part should be rejected, instead of being sold as reduced iron, as appears to have been done by some manufacturing chemists. If the preparation has been very badly made, its solution in diluted sulphuric acid will produce an intensely red color with potassium sulphocyanide. It is officially described as "a very fine, grayish-black, lustreless powder, without odor or taste; permanent in dry air. Insoluble in water or alcohol. One Gm. of Reduced Iron, when treated with 20 Cc. of diluted sulphuric acid, causes the evolution of nearly odorless hydrogen gas, which should not affect, within five minutes, paper moistened with lead acetate T.S. (limit of *sulphide*), and on applying a gentle heat, the Iron should dissolve in the acid without leaving more than 1 percent. of residue. When ignited in contact with air, it glows and is converted into black ferroso-ferric oxide. If 1 Gm. of Reduced Iron be shaken with 5 Cc. of water, the liquid should not change the color of red litmus paper. To 0.5 Gm. of Reduced Iron, contained in a small covered beaker, add 20 Cc. of diluted sulphuric acid; after the reaction has somewhat subsided, warm the liquid on a water-bath until the reaction ceases, then collect any minute undissolved residue of impure iron arsenide upon a very small filter, rinse the beaker with water, add the rinsings to the filter, and wash the residue with water until free from acid reaction. Transfer the residue to the beaker by rinsing it back, and, after adding about 0.25 Gm. of potassium chlorate and 5 Cc. of hydrochloric acid, evaporate the solution slowly to dryness on a water-bath. Dissolve the residue in sufficient water to measure 50 Cc., then add 5 Cc. of this solution to 5 Cc. of a saturated solution of sulphurous acid and heat the liquid on a water-bath for fifteen minutes, until all traces of sulphurous acid have been removed. The resulting solution should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17)."
U. S. "A fine grayish-black powder, strongly attracted by the magnet, and producing metallic streaks when rubbed with firm pressure in a mortar. It dissolves in *hydrochloric acid* with the evolution of hydrogen, and without any smell of hydrogen sulphide, and the solution gives a light blue precipitate with *solution of potassium ferrocyanide*. If 0.25 gramme be added to a hot solution of 1 gramme of *copper sulphate* in 15 cubic centimetres of *water*, in a flask that can immediately be well corked, and the whole be shaken occasionally during ten minutes, the liquid, after being rapidly filtered with the minimum of exposure to air, and acidulated with sulphuric acid, should not cease to yield a blue precipitate with *solution of potassium ferricyanide* until at least 33.7 cubic centimetres of the *volumetric solution of potassium bichromate* have been added." Br.

Assay for Metallic Iron.—"Introduce about 2.6 Gm. of iodine into a 100 Cc. flask and weigh accurately, then add 6 Cc. of water, 2 Gm. of potassium iodide, and 0.555 Gm. of Reduced Iron. Securely stopper the flask, and, after thoroughly mixing the contents by rotating the flask, set it aside for one hour. Then dilute the contents with sufficient distilled water to make the liquid measure exactly 100 Cc., mix well, and to 25 Cc. of this solution slowly add tenth-normal sodium thiosulphate V.S., with constant stirring, until the last trace of brown color has been discharged. Divide the weight of iodine taken, by 0.02518, and subtract from the quotient twice the number of Cc. of tenth-normal sodium thiosulphate V.S. used; the remainder represents the percentage of metallic iron present in the Reduced Iron, and this should not be less than 90 percent.

NOTE.—The percentage purity of the iodine employed should be accurately determined by a previous experiment, and in place of the 2.6 Gm. above directed, its equivalent in pure (100 percent.) iodine may be taken (see PART III, Test No. 137)." *U. S.*

An examination of the commercial *Reduced Iron* has been made and the results given in *Proc. A. Ph. A.*, 1894, 172, 292. O. Wilner (*A. J. P.*, 1881, 15) states that: 1. The amount of metallic iron in reduced iron can be accurately determined by treatment with mercuric chloride and titration with potassium permanganate. 2. If metallic iron be treated by the aid of a gentle heat with an excess of a concentrated solution of mercuric chloride, mercurous chloride and metallic mercury will be separated, and the metallic iron pass as ferrous chloride into solution; the ferrous and ferric oxides which may be present remain undissolved, and therefore do not prevent the estimation of the amount of metallic iron in the reduced iron. 3. The amount of ferrous oxide in the preparation may be estimated by treating the same portion with hydrochloric acid, digesting the mixture in a closed vessel until the finely divided ferrous oxide becomes dissolved, and titrating with potassium permanganate. 4. The ferric chloride which is thus formed at the same time has no appreciable action upon the precipitated metallic mercury and mercurous chloride.

Uses.—Powder of iron, reduced from the oxide by hydrogen, was first prepared for medicinal purposes by Quevenne and Miquelard of Paris. It is one of the best of chalybeate tonics, nearly free from astringency, and according to Quevenne and Costes of Bordeaux, yields the largest proportion of iron to the gastric juice. The chief objection to it is the difficulty of obtaining it well prepared. Much of the powder of iron found in commerce is not to be depended on, in consequence of imperfect reduction. Observations to determine its therapeutic value, compared with that of the other ferruginous preparations, were

made by Costes, for nearly four years, at the Saint-André hospital of Bordeaux, with results highly favorable to it. It is sometimes prepared with chocolate in the form of lozenges.

Dose, one to three grains (0.065 to 0.20 Gm.) several times a day, given in powder or in pill.

FICUS. U. S., Br.

FIG

(fīcūs)

"The partially dried fruit of *Ficus Carica* Linné (Fam. *Moraceæ*)." *U. S.* "The dried fleshy receptacles of *Ficus Carica*, Linn." *Br.*

Caricæ, *Ficus Passa*, *Fici*, *Fructus Caricæ*; *Figue*, *Fr. Cod.*; *Feigen*, *G.*; *Fichi*, *It.*; *Higos*, *Sp.*

Engler and Prantl divide the *Urticacæ* into three distinct orders,—viz., *Urticacæ* proper, including *Urtica*; *Ulmacæ*, including *Ulmus*; and the *Moracæ*, including *Ficus*, *Humulus*, and *Cannabis*.

The genus *Ficus* yields a number of economic products. Many species possess a milky juice containing caoutchouc, as *F. elastica*, Roxb., of Sumatra, etc. Some of the juices are employed externally as well as internally, as that of *F. indica*, L. Some possess anthelmintic properties, as *F. anthelmintica*, Mart. Some yield gum lac or shellac as a result of the puncture of an insect, as *F. religiosa*, L., *F. laccifera*, Roxb.; and some are esteemed for their fruits, as *F. Carica*, L., *F. religiosa*, L., etc.

Ficus Carica, Willd., *Sp. Plant.* iv. 1131; Woodv., *Med. Bot.*, p. 714, t. 244.—The fig tree, though often not more than twelve feet high, sometimes rises in warm climates twenty-five or even thirty feet. Its trunk, which seldom exceeds seven inches in diameter, is divided into numerous spreading branches, covered with a brown or ash-colored bark. Its large, palmate leaves, usually divided into five obtuse lobes, are deep green and shining above, pale green and downy beneath, and stand alternately on strong, round footstalks. The flowers are situated within a common receptacle, placed upon a short peduncle in the axils of the upper leaves. This receptacle, the walls of which become thick and fleshy, constitutes what is commonly called the fruit; though this term is, strictly speaking, applicable to the small seed-like bodies found in great numbers on the internal surface of the receptacle, to which they are attached by fleshy pedicels. Cultivation has produced in the fig, as in the apple and peach, a great diversity in shape, size, color, and taste. It is usually, however, turbinate, or top-shaped, umbilicate at the large extremity, of the size of a small pear, of a whitish, yellowish, or reddish color, and of a mild, mucilaginous, saccharine taste. The dried figs can be partially restored to their original shape by soaking. The fig tree is supposed to have

come originally from the Levant. It was introduced at a very early period into various parts of the south of Europe, and is now very common throughout the whole basin of the Mediterranean, particularly in Italy and France. Large numbers of Syrian fig trees were planted in the Pomona Valley, California, in 1890, and California figs are now commercial articles. To hasten the ripening of the fruit, it is customary to puncture it with a sharp pointed instrument covered with olive oil. *Caprification* consists in attaching branches of the wild fig tree to the cultivated plant. The fruit of the former contains great numbers of the eggs of insects of the genus *Cynips*, the larvæ of which, as soon as they are hatched, spread themselves over the cultivated fruit, and, by conveying the pollen of the male organs over which they pass to the female florets, hasten the impregnation of the latter, and cause to quickly come to perfection the fig which might otherwise ripen very slowly, or wither and drop off before maturity. In California the great difficulty in cultivating figs was found to be to get a *Cynips* which would flourish in the climate. According to Landerer, the unripe fig contains an irritant juice, which inflames the skin, and may even disorganize it. (See *A. J. P.*, xxxiii. 215.) The figs, when perfectly ripe, are dried by the heat of the sun, or in ovens. Those imported into this country come chiefly from Smyrna, packed in drums or boxes. They are more or less compressed, and are usually covered in cold weather with a whitish saccharine efflorescence, which softens in the middle of summer and renders them moist. The best are yellowish or brownish, somewhat translucent when held to the light, and filled with a sweet viscid pulp, in which are lodged numerous small yellow seeds. They are much more saccharine than is the fresh fruit. Their chief constituents are grape sugar, and gum or mucilage. An average of several analyses of dried figs as quoted by Königs (*Nahrungs und Genussmittel*, 3te Aufl., Bd. i. 781) gives—water, 31.20; nitrogenous material, 4.01; sugar, 49.79; ash, 2.86. Reckoned on the weight of absolutely dry material, the nitrogenous matter amounted to 5.75 per cent. and the sugar to 72.26 per cent. They are officially described as being “usually compressed, of irregular shape, fleshy, brownish or yellowish, frequently with an efflorescence of sugar; apex with a small scaly orifice; base with a scar or short stalk; internally hollow, with numerous small, brownish-yellow, glossy and hard akenes; odor distinct, fruity; taste sweet, pleasant.” *U. S.*

Uses.—Figs are nutritious, laxative, and demulcent. In the fresh state they are considered, in the countries where they grow, a wholesome and agreeable aliment, and have been employed from time immemorial. They are prone, however, when eaten freely, to produce flatulence, pain in the bowels, and diarrhœa. Their chief medicinal use is as a laxative article of diet in constipation. They occa-

sionally enter into demulcent decoctions, and, roasted or boiled, and split open, are sometimes applied as a cataplasm to inflamed gums.

FLUIDEXTRACTA.¹ *U. S.* (Br.)

FLUIDEXTRACTS

(flû-îd-êx-trăc'tă)

Extracta Liquida, *Br.*; Fluid Extracts; *Extraits liquides*, *Fr.*; *Extracta fluida*, *P. G.*; *Fluidextrakte*, *Flüssige Extrakte*, *G.*

Fluidextracts were first introduced into the *U. S. P.* of 1850 as a distinct class of preparations, the fluidextract of sarsaparilla being the only one previously directed, either in our own official code or by the British Colleges. Now we have eighty-five that are official, besides large quantities of non-official fluidextracts annually produced. They are now perhaps the most important class of liquid preparations in use. Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form, a cubic centimeter or fluigramme of any one of them now representing a gramme of the crude drug. In addition to convenience of administration, the advantage of these preparations is that, evaporation not being carried so far as in ordinary extracts, the active principles are less liable to be injured by heat. Formerly their main difficulty was the liability of substances in the liquid state to undergo spontaneous decomposition. In the *U. S. P.* of 1850 this was counteracted by means of sugar and of alcohol, but in 1865 (*A. J. P.*, 1865, p. 50) Taylor proposed the use of glycerin, which was adopted in the *U. S. P.* 1870 revision. Glycerin, while it exerts a powerful preservative influence, possesses the valuable property of dissolving matters deposited by some of the fluidextracts when made with sugar, as in the old official recipes. Consequently these fluidextracts were much clearer and better preparations than were the old ones. Subsequent experience with these fluidextracts showed that the use of glycerin should be circumscribed, and that it had been employed too freely in the *U. S. P.* 1870 formulas. The solvent powers of glycerin are so great that the fluidextracts were frequently loaded with many inert principles, which it dissolved, giving them a dense, rich appearance, without increasing their activity. As the primary object of fluidextracts is concentration, suitable menstrua should in each case be selected with the single object of dissolving and retaining permanently the active constituents of the drug.

¹ The Latin title *Extractum* — *Fluidum* formerly used for Fluid Extracts was dropped by the *U. S. P.* (8th Rev.) because of the confusion which resulted from the necessary bringing together of the extracts and fluid extracts due to a strict alphabetical arrangement; the name “fluidextractum” is now used for “fluidextract” and the latter made one word; this of course brings the fluidextract under the letter F instead of the letter E under which extracts and fluidextracts were formerly both classed.

The present fluidextracts are of the same strength as those formerly official, and the formulas are based upon the theory that from a given weight of drug an amount of fluid-extract shall be made equal in measure to the bulk of the same weight of distilled water; in other words, upon the relation of gramme to cubic centimeter.¹ Although the metric system is admirable in practice, some may prefer to use ordinary weights and measures; in such cases, to make 20 fluidounces of a fluidextract 19 troyounces of drug will be required, while if avoirdupois weight is preferred, the most convenient relation to recollect will be that 50 avoirdupois ounces are required to make 48 fluidounces, or three pints, of a fluidextract. It has been repeatedly proposed to make 50 per cent. tinctures or half-strength fluidextracts, the main object being to secure more representative preparations when made on the small scale. Experiments by Sayre, Gregory, Patch, and others prove that half-strength fluidextracts possess no advantages over those of official strength. (*D. C.*, 1897, 119, 147.) The general formula for the preparation of fluid-extracts does not differ materially from that formerly official; the length of time required for maceration has been judiciously reduced, while the quantity reserved has been generally slightly increased, although the formulas are not uniform in this respect. The fact cannot escape observation that there has been a close study of the solubilities, physical properties, and individuality of each drug, while uniformity among the formulas has not been sought for, so much as the best method of producing the fluidextract. The general formula may be expressed as follows. 1000 Gm. of the powdered drug are moistened with a certain quantity of menstruum, packed in a suitable percolator, and enough menstruum added to saturate the powder and leave a stratum above it; the lower orifice of the percolator is closed when the liquid begins to drop, and the percolator is closely covered to prevent evaporation and permit maceration for a specified time; additional menstruum is poured on and percolation continued until the drug is exhausted. Usually from seven hundred to nine hundred cubic centimeters of percolate are reserved, and the remainder evaporated to a soft extract; this is to be dissolved in the reserved portion, and enough menstruum added to make the fluid-extract measure 1000 Cc. The precipitation experienced heretofore, when the evaporated weak percolate was added to the reserved portion, is considerably diminished by causing the former to be evaporated to a soft extract. This precipitation, formerly noticed more particularly in alcoholic fluidextracts, was due to the

greater volatility of the alcohol in the weak percolates, which, when evaporated, left the residue to a great extent aqueous; when this was added to the strongly alcoholic reserved portion, a precipitation of resinous and frequently active matter took place, which necessitated the storing of the fluidextract until precipitation ceased, and subsequent filtration. This is not altogether avoided by evaporating to a soft extract, but the loss of activity through precipitation is thus greatly diminished. Fluid-extracts invariably deposit insoluble matter upon standing, and those made in warm weather, owing to the greater solvent powers of the menstrua (due to the elevated temperature) are found to deposit more freely than the same kind of fluidextracts if made in the winter time with menstrua correspondingly reduced in temperature.

A useful distillatory apparatus has been contrived by Joseph P. Remington for recovering alcohol from weak percolates, and for general pharmaceutical uses. The still shown in the cut is the new form. It is made of tinned copper, the still body holding about three gallons; the condenser has seven straight tubes

surrounded with the cold water introduced by a rubber tube from a hydrant or bucket of water placed higher than the still, and carried off as it becomes warmed by the tube shown at the upper part of the condenser. By a siphon arrangement not shown in the cut, the still can be fed from a reservoir while distillation is in progress, thus using a three gallon still where otherwise a much larger one would have been necessary. The joints are carefully ground, and troublesome lutes and water joints are entirely superseded. The condenser, having straight tubes instead of a spiral one, is easily cleaned, and is powerful enough to condense a gallon of alcohol in thirty minutes. The still may be set into a kettle partly filled with water and thus used as a water bath, or a shallow tinned copper dish with flat rim, which accompanies the still, may be placed between the two brass ring bands and clamped securely. (*A. J. P.*, May, 1879.) Remington's *Practice of Pharmacy*, fourth ed., page 158.

For valuable papers on percolation and fluid-extracts, by William Procter, E. R. Squibb,

¹ The following table shows the relation of the crude drug to the fluidextract when made by the process of the U. S. P. 8th Rev. and when made by that of the U. S. P. 1870:

Weight of Drug.	Measure of Fluidextract.	
	U. S. P. 8th Rev.	U. S. P. 1870.
100 grammes of drug make	100 Cc.	94.9 Cc.
100 troyounces of drug make	105.4 fluidounces.	100 fluidounces.
100 avoirdupois ounces of drug make	96 fluidounces.	91.1 fluidounces.

Alonzo Robbins, and others, see *Proc. A. Ph. A.*, 1859, p. 265; 1863, p. 222; *A. J. P.*, 1878, pp. 209, 329; 1873, pp. 85, 189.

Several methods have been suggested for preparing fluidextracts more economically. The use of acetic acid as a menstruum to replace alcohol or diluted alcohol has the merit of economy (see *Extracta*, also *A. J. P.*, 1899, 1-14; *Proc. Pennsylvania Pharm. Assoc.*, 1898, 116; *A. J. P.*, 1898, 543; *A. J. P.*, 1899, 67; *Ph. Era*, 1898, 796; *Proc. Minnesota Pharm. Assoc.*, 1902, 103; *West. Drug.*, 1903, 652).

The most important modification is the plan of repercolation, as proposed by E. R. Squibb, for this class of preparations as well as the dry extracts.

Repercolation.—In consequence of the existing high price of alcohol, it is important to adopt some plan by which, while the ends aimed at are attained, the consumption of the menstruum used in percolation may be diminished. This object has been accomplished, to a considerable extent, by E. R. Squibb of Brooklyn, N. Y., by a modification of the process of percolation to which he has given the name at the head of the present paragraph. As defined by the author, repercolation consists in the successive application of the same percolating menstruum to fresh portions of the substances to be percolated. The result is that the same menstruum, acting repeatedly on unexhausted portions of the substance, becomes concentrated to the greatest possible extent, so that much of the menstruum is saved, while subsequent evaporation is avoided, which is itself an object of great importance in the preparation of extracts. It is obvious that repercolation is not applicable to the preparation of infusions, decoctions, tinctures, etc., in which the object in general is less a high degree of concentration than precision in the strength of the preparation, and consequently in the dose. It is to the extracts and fluidextracts that the process is peculiarly adapted, and there now remains no doubt whatever of the great value of the improvement. One of its disadvantages is that the substance treated is less completely exhausted than when the proceeding is inverted, and fresh portions of menstruum are made to act on the same material until the latter is deprived of all its soluble matter. But the loss in this way is trifling, compared with the gain when a menstruum as high-priced as alcohol is employed.

Another practical disadvantage is the inconvenience of keeping the weak percolates, as these have to be labelled, numbered, and stored away for use until the same operation is repeated. In deciding when to adopt it, the operator will of course be influenced by the relative value of the drug and the menstruum. In order to secure the most favorable results in repercolation, certain methods of proceeding are advisable in various steps of the process, differing with the character of the substance to be acted on; and these can be determined only

by a careful study, confirmed by repeated experiment. Squibb used repercolation exclusively on the large scale in the manufacture of extracts and fluidextracts, and applied it especially to the preparation of fluidextracts of cinchona; and since his first paper, which was reproduced in the 14th revision of the U. S. Dispensatory, p. 1164, he introduced several improvements, which are intended to make the process useful to the apothecary in his everyday work. By presenting in a note below an abstract of his plan of proceeding in this case, we can impress on the mind of the pharmaceutical student the lessons applicable to the case more forcibly than could be done by a general description.¹

The plan of N. Spencer Thomas consists in exposing the substance to be acted on to successive expressions, by means of a press, with the menstruum divided into different portions, so that fresh portions of liquid are brought to act on the same solid body in different stages of exhaustion, and then mixing the expressed liquids. The due proportion between the weight of the medicine and the bulk of the ultimate fluidextract is secured by regulating the measure of the last added portion of menstruum, which, in the process as described by Thomas, is the third. Whatever may be the advantages of this method—and it is not with-

¹*Squibb's Process for Fluidextract of Cinchona by Repercolation.*—"Take of Yellow Cinchona, in powder No. 50, 32 parts; Stronger Alcohol, sp. gr. .819, 2 parts; Glycerin, sp. gr. 1.250, 1 part; Water, 2 parts. Weigh the Stronger Alcohol, Glycerin, and Water in succession, in any convenient quantity at a time, into a tared bottle, and mix them thoroughly for a menstruum.

Moisten 8 parts of the Cinchona with eight parts of the menstruum, by thoroughly mixing them, and allow the mixture to stand 8 hours in a closely covered vessel. Then pass the moist powder through a No. 8 sieve, and pack it firmly in a percolator. Pour menstruum on top until the mass is filled with liquid and a stratum remains on top unabsorbed; cover the percolator closely and macerate for 48 hours. Then arrange the percolator for an automatic supply of menstruum, and start the percolation at such a rate as to give 1 part of percolate in about 4 hours. Reserve the first 6 parts of percolate, and continue the percolation until the Cinchona is exhausted, separating the percolate received after the reserved portion into fractions of about 8 parts each. Moisten a second portion of 8 parts of the Cinchona with 8 parts of the weak percolate,—the first portion that was obtained next after the reserved percolate,—and allow the moist powder to stand for 8 hours in a vessel closely covered. Then pack it moderately in a percolator, and supply the percolator automatically with the remaining fractions of the weak percolate in the order in which they were received, and finally with fresh menstruum until the Cinchona is exhausted. Percolate in the same manner and at the same rate as with the first portion of Cinchona, and, reserving 8 parts of the first percolate, separate the weaker percolate into fractions of about 8 parts each. Percolate the third and fourth portions of 8 parts each of the Cinchona in the same way as the second portion. Finally mix the four reserved percolates together to make 30 parts of finished fluidextract; and having corked, labelled, and numbered the bottles containing the fractions of weak percolate, set them away until the process for Cinchona is to be resumed.

When this fluidextract is to be again made, repeat the process as with the second portion, and reserve 8 parts of the first percolate as finished fluidextract from each 8 parts of Cinchona from that time forward so long as the fractions of weak percolate are carried forward with which to commence each operation." See also Squibb's percolator, 16th edition U. S. D., p. 600.

out its recommendations—it is liable to the objection of loss of alcohol through exposure during expression. Another method of limiting the quantity of alcohol used has been proposed by S. P. Duffield of Detroit. It consists in macerating, for from six to ten days, the medicine to be acted on, previously deprived, by means of a vacuum apparatus, of all the air, and of all readily volatilizable matter contained in its pores, with a certain volume of the menstruum, which is forced through a tube into the vacuum pan by atmospheric pressure, and thus brought into the most intimate contact with all parts of the powder. The process is completed by submitting the mass thus impregnated to hydraulic pressure, and, after allowing the liquid to settle in glass carboys, drawing off the clear liquid into bottles. It is obviously inapplicable to substances whose virtues depend in any considerable degree upon readily volatilizable constituents. Campbell (*A. J. P.*, xlii. 17) proposed a method for doing away with the use of heat, which, however, although in some cases it may do well, cannot be relied upon for the complete exhaustion of all drugs. Sixteen troyounces of the powder are moistened with four to six fluidounces of the menstruum (usually alcohol), and packed in a glass funnel, a piece of sponge having previously been put in the beak of the funnel; the surface of the powder is covered with a disk of paper, and twelve fluidounces of menstruum poured on. When the sponge becomes saturated, the beak of the funnel is corked tightly and the whole set aside for four days, at the end of which time the percolation may be allowed to proceed without further addition of menstruum. J. W. Mill has called attention to the advantage of separating the powder into fine and coarse parts by means of sieves and packing the finer powder at the bottom.

H. Biroth (*Pharm.*, April, 1877) proposes the method which he terms “insuccation,” for making non-alcoholic fluidextracts; the advantages claimed for it are simplicity and economy. Colaz prepares fluidextracts from fresh plants by bruising and crushing them, and placing the mass in a dialyzer suspended in 90 per cent. alcohol; when the dialysis is completed, the liquid is evaporated to free it from alcohol, the remaining aqueous liquid retaining the active constituents in the proportions in which they are found in the plant. (*Ph. Post*, xxix. 271.) Haussmann (*A. J. P.*, 1895, 291), after examining a large number of commercial fluidextracts, records his results in tabular form, and considers that there is great variation in the quality, due to deviation from pharmacopoeial processes.

J. U. Lloyd proposes to recover the alcohol which remains absorbed by the residue after percolation, by mixing the wet residues with an equal bulk or less of dry sawdust, and then percolating this with water. (*A. J. P.*, June, 1877.) Wm. M. Thomson of Philadelphia, devised a very complete method of preparing

fluidextracts on a large scale; the principles of his process are maceration and percolation *in vacuo*, and although the principles which have been applied have been long known, and similar apparatus used by Duffield and others, there are many useful practical points which merit a notice in detail. The percolators are egg-shaped, and made of tinned copper; they are capable of being tightly covered, and communicate by means of stopcocks above and below, and iron and stout rubber tubing, with a very efficient double acting air pump. The moistened powder is packed tightly in the percolator, and the cover securely bolted on. The stopcock in the cover is now opened, which communicates with the air pump and a partial vacuum created in the space above the moistened drug; the stopcock is now closed and another stopcock in the cover opened, which communicates by a tube with the reservoir containing the menstruum. The menstruum, of course, quickly penetrates the powder, taking the place of the interstitial air, and when the powder is saturated it is permitted to macerate *in vacuo* a sufficient length of time. To start percolation, a receiver is connected with the beak of the percolator, and, the air being exhausted from it, the percolate at once makes its appearance. When the flow slackens, air may be forced by the pump in the space above the powder, if desired, and the receiver again exhausted below. In this way, it can be seen, entire control of these powerful physical forces may be secured. The advantages are very apparent in preventing the loss of volatile principles and alcohol, while protecting from chemical change caused by exposure to the air. It is quite possible to make official fluidextracts without recourse to subsequent evaporation of weak percolate. For a cut of this apparatus, see *A. J. P.*, 1882.¹

¹ The processes for the following Fluidextracts were omitted in the 8th revision of the U. S. P., but as they are still sometimes used we append the processes of the U. S. P. 1890; other fluidextract formulas of the U. S. P. 1890 will be found in PART II under their respective drugs.

Extractum Arnice Radicis Fluidum. U. S. (1890). *Fluid Extract of Arnica Root.*—“Arnica Root, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol with two hundred and fifty cubic centimeters [or 8 fluidounces, 217 minims] of Water, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Arnica Root is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms].”

Assaying fluidextracts.—The number of assay processes for fluidextracts was materially increased in the U. S. P. (8th Rev.) for preparations made from alkaloidal drugs. The process

in each case differs but slightly from the process used for the corresponding drug; they will be found in the succeeding pages under their appropriate headings.

U. S. 1890. This fluidextract is of a clear, reddish-brown color, possessing little odor, and having an acid taste.

Extractum Colchici Radicis Fluidum. *U. S. (1890).* **Fluid Extract of Colchicum Root.**—"Colchicum Root, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with three hundred and fifty cubic centimeters [or 11 fluidounces, 400 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Colchicum Root is exhausted. Reserve the first eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S. 1890.*

This fluidextract is not essentially different from that formerly official. The present menstruum will thoroughly exhaust the root, and this fluidextract is now a good preparation. It is of a reddish-brown color and bitter taste. Dose, from two to eight minims (0.12 to 0.5 Cc.).

Extractum Kusso Fluidum. *U. S. (1890).* **Fluid Extract of Kousoo.** **Extractum Brayeræ Fluidum.** *U. S. 1880.* **Fluid Extract of Brayera.**—"Kousoo, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Kousoo is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate. Distill off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion and add enough Alcohol to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S. 1890.* This preparation, although undoubtedly active, was very properly dropped from the U. S. P. because of its containing so large a percentage of alcohol and its extremely disagreeable taste. It may be given in doses of from one-half to one fluidounce (15 to 30 Cc.).

Extractum Gossypii Radicis Fluidum. *U. S. (1890).* **Fluid Extract of Cotton Root Bark.** **Extractum Gossypii Radicis Corticis Liquidum.** *Br. Add. Liquid Extract of Cotton Root Bark.*

"Cotton Root Bark, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol, and, having moistened the powder with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Alcohol, until the Cotton Root Bark is exhausted. Reserve the first seven hundred cubic centimeters [or 23 fluidounces, 321 minims] of the percolate; and evaporate the remainder to a soft extract;

dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S. 1890.* "Cotton Root Bark, in No. 30 powder, 20 ounces (Imperial) or 1000 grammes; Glycerin, 5 fl. ounces (Imp. meas.) or 250 cubic centimeters; Alcohol (90 per cent.), a sufficient quantity. Mix the Glycerin with fifteen fluid ounces (Imp. meas.) or seven hundred and fifty cubic centimeters of the Alcohol; mix the powder with ten fluid ounces (Imp. meas.) or five hundred cubic centimeters of this menstruum; pack firmly in a percolator; add more of the menstruum, and when the liquid begins to drop close the lower orifice of the percolator; set aside for forty-eight hours; then allow percolation to proceed, gradually adding the remainder of the menstruum and then more of the Alcohol until the Cotton Root Bark is exhausted. Reserve the first fourteen fluid ounces (Imp. meas.) or seven hundred cubic centimeters of the percolate; remove the alcohol from the remainder by distillation; evaporate the residue to the consistence of a soft extract; dissolve this in the reserved percolate; add enough of the Alcohol to produce one pint (Imp. meas.) or one thousand cubic centimeters of the Liquid Extract." *Br.* This is one of the fluidextracts which is improved by the use of glycerin: the menstruum selected prevents the gelatinization which was a troublesome objection to the fluidextract of the Pharmacopœia of 1870. J. U. Lloyd prefers a menstruum composed of ten fluidounces of alcohol and three fluidounces each of glycerin and water, finishing the percolation with a mixture composed of ten fluidounces of alcohol and six fluidounces of water. It is a deep-reddish liquid, and well represents the root. The dose is from half a fluidrachm to a fluidrachm (1.8 to 3.75 Cc.).

Extractum Scoparii Fluidum. *U. S. (1890).* **Fluid Extract of Scopolia.** **Fluid Extract of Broom.** "Scopolia, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with three hundred and fifty cubic centimeters [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Scopolia is exhausted. Reserve the first eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S. 1890.* It is difficult to avoid precipitation in the preparation, but fortunately the precipitate is not active. Dose, from twenty to forty minims (1.3 to 2.5 Cc.).

Extractum Stramonii Seminis Fluidum. *U. S. (1890).* **Fluid Extract of Stramonium Seed.** [**Extractum Stramonii Fluidum.** *U. S. P. 1880.*] "Stramonium Seed, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with two hundred cubic centimeters [or 6 fluidounces, 366 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before. The Stramonium Seed is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure one thousand cubic

FLUIDEXTRACTUM ACONITI. U. S.

FLUIDEXTRACT OF ACONITE [Extractum
Aconiti Fluidum, Pharm. 1890]

(fû-jd-êx-trăc'tûm âc-q-nî'ti)

Fluid Extract of Aconite Root; Extrait Liquide de Racine d'Aconit, *Fr.*; Flüssiges Eisenhutknollen-extrakt, *G.*

* "Aconite, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Aconite is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, mixing thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of aconitine in the remainder of the liquid, add to this enough menstruum to make each *one hundred cubic centimeters* of the finished Fluidextract contain 0.4 Gm. of aconitine." U. S.

Assay. U. S. (8th Rev.)—"Fluidextract of Aconite, *ten cubic centimeters*; Ether, Distilled Water, Ammonia Water, Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., each, a *sufficient quantity*. Transfer 10 Cc. of Fluidextract of Aconite by means of a graduated pipette to a porcelain dish, and evaporate it carefully to dryness on a water-bath at a temperature not exceeding 60° C. (140° F.). Add 5 Cc. of tenth-normal sulphuric acid V.S. and 10 Cc. of distilled water. When the extract is dissolved, filter the liquid into a separator, washing the dish and filter with about 40 Cc. of distilled water; when this has passed through, add 25 Cc. of ether and 2 Cc. of ammonia water to the separator, and agitate

centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890. This is a fluidextract the menstruum of which is well adapted for thoroughly exhausting the seed. It is of a dark brown color. The dose is from one to two minims (0.06 to 0.12 Cc.).

for one minute. Draw off the lower layer into a flask and filter the ether-solution into a beaker. Return the contents of the flask to the separator, add 15 Cc. of ether, and agitate for one minute. Draw off the lower layer into the flask and filter the ether-solution into the beaker. Repeat, with two other portions of 10 Cc. each of ether. Evaporate the ether-solution to dryness, and dissolve the residue in 3 Cc. of tenth-normal sulphuric acid V.S. diluted with 20 Cc. of distilled water. Add to the solution 5 drops of hematoxylin T.S., and then carefully run in fiftieth-normal potassium hydroxide V.S. until a violet color is produced, the transition stages being as follows: first yellow, then green, finally passing into violet. Divide the number of Cc. of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 3 (the 3 Cc. of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.064, and this product by 10, which will give the weight in grammes of aconitine contained in *one hundred cubic centimeters* of the Fluidextract of Aconite."

This preparation of aconite root was found useful by Procter as a basis for making the other preparations of aconite,—the plaster, extract, tincture, or liniment. The fluidextract is of a bright deep reddish-brown color. It will doubtless be frequently employed as an addition to liniments for obtaining the peculiar effects of aconite.

Dose, one-half to one minim (0.03 to 0.06 Cc.), but on account of its very powerful character it should always be used with caution, beginning with the smallest dose.

FLUIDEXTRACTUM APOCYNII. U. S.

FLUIDEXTRACT OF APOCYNUM [Extractum
Apocyni Fluidum, Pharm. 1890]

(fû-jd-êx-trăc'tûm â-pöc'y-nî)

Fluidextract of Canadian Hemp; Extrait Liquide de Chanvre du Canada, *Fr.*; Flüssiges Canadisch-Hanfwurzelextrakt, *G.*

* "Apocynum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly,

gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water, until the Apocynum is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” U. S.

This fluidextract represents the activity of apocynum in a very satisfactory manner.

Dose, five to ten minims (0.3 to 0.6 Cc.); as an emetic, fifteen to twenty minims (0.9 to 1.3 Cc.).

FLUIDEXTRACTUM AROMATICUM. U. S.

AROMATIC FLUIDEXTRACT [Extractum
Aromaticum Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm âr-q-mât'-i-cûm)

Extrait liquide aromatique, Fr.; Flüssiges Aromatisches Extrakt, G.

* “Aromatic Powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Aromatic Powder is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” U. S.

This is a valuable fluidextract; it is an excellent aromatic in concentrated form, and will be found very useful not only as an addition to liquids when an aromatic is desired, but its concentrated form permits its use in small quantities with dry powders, like pepsin, bismuth subnitrate, etc., when desired for administration. It is rarely used alone.

Dose, from ten to twenty minims (0.6 to 1.3 Cc.), diluted with water, or dropped on sugar.

FLUIDEXTRACTUM AURANTII AMARI. U. S.

FLUIDEXTRACT OF BITTER ORANGE PEEL
[Extractum Aurantii Amari Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm âu-rân'ti-i â-mâ'ri)

Extrait liquide d'Ecorce d'Orange amère, Fr.; Flüssiges Pomeranzenschalenextrakt, G.

* “Bitter Orange Peel, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it moderately in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Orange Peel is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” U. S.

This fluidextract is useful as a tonic; when dry, the bitter orange peel having very little oil present, there is necessarily little agreeable orange flavor to the fluidextract. Monroe Bond recommends a *Fluidextract of Sweet Orange Peel*, made with a menstruum of seven parts of alcohol and one of glycerin. (*A. J. P.*, 1873, p. 482.)

Dose, fifteen to thirty minims (0.9 to 1.8 Cc.).

FLUIDEXTRACTUM BELLADONNÆ RADICIS. U. S. (Br.)

FLUIDEXTRACT OF BELLADONNA ROOT
[Extractum Belladonnæ Radicis
Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm bêl-lâ-dôn'næ râ-dî'cis)

“A Liquid Extract containing ¾ grain of the alkaloids of Belladonna Root in 110 minims (0.75 gramme in 100 cubic centimetres).” Br.

Extractum Belladonnæ Liquidum, Br., Extract of Belladonna; Extrait liquide de Racine de Belladone, Fr.; Flüssiges Tollkirschenwurzelextrakt, G.

* “Belladonna Root, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120

grains]; Alcohol, Water, each, a *sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Belladonna Root is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract, dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid; add to this enough menstruum to make each *one hundred cubic centimeters* of the finished Fluidextract contain 0.5 Gm. of mydriatic alkaloids from Belladonna Root." U. S.

Assay of Fluidextract of Belladonna Root. U. S. (8th Rev.).—"Fluidextract of Belladonna Root, *ten cubic centimeters*; Distilled Water, Ammonia Water, Chloroform, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., or Iodeosin T.S., each, a *sufficient quantity*. Transfer 10 Cc. of Fluidextract of Belladonna Root by means of a graduated pipette to a separator, add 10 Cc. of distilled water, 20 Cc. of chloroform, and 2 Cc. of ammonia water. Shake the separator well for one minute, and draw off the lower chloroformic layer into a second separator. Repeat the extraction with two portions of 10 Cc. each of chloroform, and draw the chloroformic solution into the second separator. To the latter add 8 Cc. of normal sulphuric acid V.S. and 20 Cc. of distilled water, shaking well for one minute. When perfectly separated draw off and reject the lower chloroformic layer, and filter the acid aqueous layer into a clean separator. Wash the separator and filter with 10 Cc. of distilled water, adding this to the clean separator. To the latter add 20 Cc. of chloroform and 4 Cc. of ammonia water, and shake well for several minutes. Draw off the lower chloroformic layer into a beaker, and repeat the extraction with two portions of 10 Cc. each of chloroform, adding the chloroformic solution to the beaker. Allow the chloroform in the beaker to evaporate on a water-bath, con-

taining warm water, until the residue is perfectly dry. To the alkaloidal residue add 5 Cc. of tenth-normal sulphuric acid V.S., and when the residual alkaloids have all dissolved, titrate the solution with fiftieth-normal potassium hydroxide V.S., using 5 drops of hematoxylin or iodeosin T.S. as an indicator. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0287, and this product by 10, to obtain the weight in grammes of mydriatic alkaloids contained in *one hundred cubic centimeters* of the Fluidextract of Belladonna Root." U. S.

"Moisten *eight ounces* (Imperial) or three hundred and twenty grammes of Belladonna Root, in No. 20 powder, with *six fluid ounces* (Imp. meas.) or two hundred and forty cubic centimetres of a mixture of seven volumes of Alcohol (90 per cent.) and one volume of Distilled Water; set aside for six hours; pack firmly in a percolator; pour over the powder *six fluid ounces* (Imp. meas.) or two hundred and forty cubic centimetres of the same alcoholic menstruum; when the liquid begins to drop, close the lower orifice of the percolator; set aside for twenty-four hours; percolate slowly, adding more of the menstruum as required; collect the percolate in small portions. Moisten a second quantity of *eight ounces* (Imp.) or three hundred and twenty grammes of Belladonna Root, in No. 20 powder, with the first *six fluid ounces* (Imp. meas.) or two hundred and forty cubic centimetres of percolate; proceed to extract this portion of the Belladonna Root in the manner directed for the first portion, but use as the menstruum the liquid collected from the first percolator. This method of percolation is to be carried out through two more quantities each of *eight ounces* (Imp.) or three hundred and twenty grammes of Belladonna Root, the third portion being extracted with the liquid from the second percolator, and the fourth portion with the liquid from the third percolator. Collect *twelve and a half fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the strong percolate from the fourth percolator.

Determine the proportion of alkaloids in the resulting strong percolate by the following analytical process.

Introduce 10 cubic centimetres into a separator, add 10 cubic centimetres of *chloroform*, 50 cubic centimetres of *water*, and a decided excess of *solution of ammonia*; agitate; set aside; separate the chloroformic solution. Twice repeat the agitation with *chloroform* and the separation. Shake the mixed chloroformic solutions with 5 cubic centimetres of *diluted sulphuric acid*, mixed with twice its volume of warm *water*; separate the chloroformic liquid and repeat the agitation with acidulated *water*. Wash the mixed acid liquids with 3 cubic centimetres of *chloroform*; then agitate with 10

cubic centimetres of *chloroform* and an excess of *solution of ammonia*. Separate the chloroformic solution; twice repeat the agitation with *chloroform* and the separation; wash the mixed chloroformic solutions with 5 cubic centimetres of *water* containing one drop of *solution of ammonia*; draw off the chloroformic layer into a counterpoised dish; evaporate on a water-bath; dry the residue below 212° F. (100° C.); weigh. Dissolve the residue in 10 cubic centimetres of a decinormal solution of hydrochloric acid (3.619 grammes of the acid, HCl, per litre) and add centinormal solution of soda (0.3976 gramme of sodium hydroxide, NaOH, per litre) until the liquid is neutral, using Tincture of Cochineal as an indicator. Deduct the measure of soda solution thus required, from 100 cubic centimetres, and multiply the remainder by 0.00287; the product will be the weight in grammes of alkaloids present in the quantity of the percolate operated upon.

From this weight calculate the amount of alkaloids in the bulk of strong percolate, and add to the latter sufficient of the alcoholic menstruum to produce Liquid Extract of Belladonna containing 0.75 gramme of alkaloids in 100 cubic centimetres, or $\frac{3}{4}$ grain in 110 minims." *Br.*

The British liquid extract represents several radical improvements in British pharmacy,—i.e., the use of repercolation with absence of heat in the process, and standardization, thus making the end product bear a definite relation towards the quantity of active constituents found in the root (0.75 per cent.). It is based upon the formula proposed by R. A. Cripps. (*P. J.*, 1895, 795.) The fluidextract of the root is a good preparation, of reddish-brown color, very different in appearance from the deep-green fluidextract of the leaves which is often seen in the market.

Dose, from one to two minims (0.06 to 0.12 Cc.).

Off. Prep.—Emplastrum Belladonnæ, *Br.*; Extractum Belladonnæ Alcoholicum, *Br.*; Linimentum Belladonnæ, *U. S.*, *Br.*; Tinctura Belladonnæ, *Br.*; Unguentum Belladonnæ, *Br.*

FLUIDEXTRACTUM BERBERIDIS.

U. S.

FLUIDEXTRACT OF BERBERIS

(flû-îd-êx-trâc'tûm bër-bër'î-dis)

Fluidextract of Oregon Grape (*Berberis Aquifolium*); Extrait liquide de Berberis (d'épine-vinette), *Fr.*; Flüssiges Berberitzenextrakt, *G.*

* "*Berberis*, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder

and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol until the *Berberis* is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluidextract was introduced into the U. S. P. (8th Rev.) for the first time. It represents the virtues of *berberis*.

Dose, half a fluidrachm to a fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM BUCHU. U. S.

FLUIDEXTRACT OF BUCHU [Extractum Buchu Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm bū'chû)

Extrait liquide de Bucco, *Fr.*; Flüssiges Buccoextrakt, *G.*

* "*Buchu*, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the *Buchu* is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The old menstruum (alcohol 75 per cent.) for this fluidextract has been restored, experience having shown that with the weaker alcohol used in the U. S. P. 1880 formula it was possible to percolate *buchu* leaves satisfactorily.

In consequence of the peculiar structure of the leaves, it is somewhat difficult to powder them in a mortar, and it will be convenient

to resort to a mill for the purpose. As the most active ingredient of buchu is volatile, the direction in the formula to set aside the first portion of tincture obtained, which is a highly concentrated solution, is peculiarly important; for, if it were subjected to evaporation, much of the volatile oil would necessarily escape. The tincture subsequently obtained probably contains a large proportion of the fixed ingredients of the leaves, and will, therefore, allow of concentration without material loss.

This fluidextract is of a dark green color, and possessed in a high degree of the sensible properties of the leaves. It acquires the odor of mint when long kept, showing that some change takes place in its volatile oil. This fluidextract affords the best means at our command for the exhibition of buchu. It is often combined with solution of potassium hydroxide with excellent results.

Dose, thirty minims to a fluidrachm (1.8 to 3.75 Cc.), three to five times a day.

FLUIDEXTRACTUM CALAMI. U. S.

FLUIDEXTRACT OF CALAMUS [Extractum
Calami Fluidum, Pharm. 1890]

(flû-jd-êx-trâc'tûm cāl'a-mî)

Extrait liquide d'Acore vrai, *Fr.*; Flüssiges Kalmswurzelextrakt, *G.*

* "Calamus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Calamus is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluidextract which was introduced with the view of bringing into use an excellent indigenous aromatic stimulant. It

will probably be most frequently used in combination with tonics in *dyspepsia* and gastric disorders to relieve *flatulence*, etc.

Dose, from five to fifteen minims (0.3 to 0.9 Cc.).

FLUIDEXTRACTUM CALUMBÆ. U. S.

FLUIDEXTRACT OF CALUMBA [Extractum
Calumbæ Fluidum, Pharm. 1890]

(flû-jd-êx-trâc'tûm cā-lûm'bæ)

Extrait liquide de Colombo, *Fr.*; Flüssiges Kolomboextrakt, *G.*

* "Calumbæ, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Calumbæ is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The formula for fluidextract of calumbæ of the U. S. P. 1870 was faulty, in directing the root to be in fine powder; the large quantity of mucilage present swelled under the influence of the menstruum, and frequently prevented the passage of the percolate; indeed, the powder will probably still be found to give trouble, and there will be some difficulty in thoroughly exhausting it; it should be slowly percolated. This extract is a yellowish-brown liquid, of an intense and purely bitter taste. The absence of tannin makes it a very desirable tonic, in combination with chalybeates.

Dose, fifteen to thirty minims (0.9 to 1.8 Cc.).

FLUIDEXTRACTUM CANNABIS INDICÆ. U. S.

FLUIDEXTRACT OF INDIAN CANNABIS
[Extractum Cannabis Indicæ Fluidum, Pharm. 1890]

(flû-jd-êx-trâc'tûm cān'na-bis in'dî-çæ)

Extrait liquide de Chanvre Indien, *Fr.*; Flüssiges Indisch-Hanfextrakt, *G.*

* "Indian Cannabis, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Indian Cannabis is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S.

This is a fluidextract which has come into use because of its convenience, and probably on account of the impression that heat injures the activity of the drug, and that the extract owes its inactivity sometimes to the influence of heat. (See *Cannabis Indica* and *Extractum Cannabis Indicæ*.) The fluidextract is of a dark green color, having the characteristic odor of the drug.

Dose, from one to two minims (0.06 to 0.12 Cc.).

FLUIDEXTRACTUM CAPSICI. U. S.

FLUIDEXTRACT OF CAPSICUM [Extractum Capsici Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm câp'si-ci)

Fluidextract of Red Pepper; Extrait liquide de Capsique, de Piment des Jardins, Fr.; Flüssiges Spanisch-Pfefferextract, G.

* "Capsicum, in No. 50 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Capsicum is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved

portion, and add enough Alcohol to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S.

The necessity for an official fluidextract of capsicum is not apparent, as the oleoresin and tincture are preparations which are well known and established. It will probably be rarely necessary to administer it internally.

Dose, from one-half to one minim (0.03 to 0.06 Cc.).

FLUIDEXTRACTUM CHIMAPHILÆ.

FLUIDEXTRACT OF CHIMAPHILA [Extractum Chimaphilæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm çhî-măph'i-læ)

Fluidextract of Pipsissewa; Extrait liquide de Pyrole ombellée, Fr.; Flüssiges Doldenblüthiges Harnkrautextract, G.

* "Chimaphila, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Chimaphila is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S.

This is a rather thick, dark brownish-green fluidextract.

Dose, a fluidrachm (3.75 Cc.).

FLUIDEXTRACTUM CHIRATÆ. U. S.

FLUIDEXTRACT OF CHIRATA [Extractum Chiratæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm çhî-ră'tæ)

Extrait liquide de Chirette, Fr.; Flüssiges Chiretta-extract, G.

* "Chirata, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims] of Diluted Alcohol, pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above

it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Chirata is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This useful fluidextract is a clear, reddish-brown liquid, of an intensely bitter taste.

Dose, half a fluidrachm (1.8 Cc.).

FLUIDEXTRACTUM CIMICIFUGÆ.

U. S. (Br.)

FLUIDEXTRACT OF CIMICIFUGA [Extractum
Cimicifugæ Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm cim-î-clî-fû-gæ)

Extractum Cimicifugæ Liquidum, Br., Liquid Extract of Cimicifuga; Liquid Extract of Actæa Racemosa; Fluidextract of Black Cohosh; Extrait liquide d'Actée à Grappes, *Fr.*; Flüssiges Cimicifugaeextrakt, *G.*

* “Cimicifuga, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Cimicifuga is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

“Cimicifuga, in No. 60 powder, *20 ounces* (Imperial) or *1000 grammes*; Alcohol (90 per cent.), *a sufficient quantity*. Mix the Cimicifuga with *two pints* (Imp. meas.) or *two thousand cubic centimetres* of the Alcohol; set aside in a closed vessel for forty-eight hours; transfer to a percolator; when the fluid ceases to pass, continue the percolation with more Alcohol, until the Cimicifuga is exhausted. Reserve the first *fifteen fluid ounces* (Imp. meas.) or *seven hundred and fifty cubic centimetres* of the percolate; evaporate the remainder to the consistence of a soft extract; dissolve this in the reserved portion; add enough of the Alcohol

to produce *twenty fluid ounces* (Imp. meas.) or *one thousand cubic centimetres* of the Liquid Extract.” *Br.*

This formula does not differ essentially from that of the U. S. Pharm. 1870. The British preparation has been modelled after that of the United States. There probably cannot be two opinions about the menstruum, although it has been asserted that a good fluidextract can be made with a menstruum of three parts alcohol and one part water. The probabilities are, however, that a portion of the resinous principle would precipitate on standing. This fluidextract is of a deep reddish-brown color, and thoroughly represents the drug.

Dose, from fifteen minims to one fluidrachm (0.9 to 3.75 Cc.).

Off. Prep.—Extractum Cimicifugæ, *U. S.*

FLUIDEXTRACTUM CINCHONÆ.

U. S. (Br.)

FLUIDEXTRACT OF CINCHONA [Extractum
Cinchonæ Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm cîn-phô-næ)

“A Liquid Extract containing 5 grains of the alkaloids of Red Cinchona Bark in 110 minims (5 grammes in 100 cubic centimetres).” *Br.*

Extractum Cinchonæ Liquidum, Br., Liquid Extract of Cinchona; Extractum Chinæ Callisayæ Fluidum; Extrait liquide de Quinquina jaune, *Fr.*; Flüssiges Kallsayarindenextrakt, Flüssiges Chinaextrakt, *G.*

* “Cinchona, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol and *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, and, when the liquid in the percolator has disappeared from the surface, gradually pour on a mixture of Alcohol and Water, made in the proportion of *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol to *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and continue the percolation slowly until the Cinchona is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly.

Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of anhydrous ether-soluble alkaloids in the remainder of the liquid, and add to this enough of a mixture of Alcohol and Water, using the same proportions as before, to make each *one hundred cubic centimeters* of the Fluidextract contain 4 Gm. of anhydrous ether-soluble alkaloids from Cinchona." U. S.

Assay of Fluidextract of Cinchona. U. S. (8th Rev.).—"Fluidextract of Cinchona, *ten cubic centimeters*; Ether, sp. gr. not above 0.720 at 25° C. (77° F.), Normal Sulphuric Acid V.S., Ammonia Water, Chloroform, each, *a sufficient quantity*. Transfer 10 Cc. of Fluidextract of Cinchona by means of a graduated pipette to an Erlenmeyer flask of 200 Cc. capacity, and add a mixture of 100 Cc. of ether, 25 Cc. of chloroform, and 10 Cc. of ammonia water. Insert the stopper securely, and shake the flask vigorously, at intervals, during ten minutes. Allow the liquids to separate, decant into a measuring cylinder exactly 66 Cc. of the supernatant liquid (representing 5 Cc. of the Fluidextract), and transfer this to a separator, rinsing the cylinder with 5 Cc. of ether and adding this to the separator. Add to the latter about 10 Cc. of normal sulphuric acid V.S., or enough to make the solution distinctly acid, and shake the separator vigorously for several minutes, and when the liquids have completely separated, draw off the lower layer into a second separator. To the first separator add 5 Cc. more of normal sulphuric acid V.S., and 5 Cc. of distilled water, shake it for several minutes, and when the liquids have separated, draw off the lower layer into the second separator. Now add 5 Cc. of distilled water to the first separator, shake it, separate as before, and then draw off the lower aqueous layer into the second separator. To the second separator, add 25 Cc. of ether, a small piece of red litmus paper, and then, gradually, ammonia water, keeping the temperature of the liquids below 25° C. (77° F.), until the reaction is alkaline. Then shake the separator vigorously for two minutes, and allow the liquids to stand for ten minutes at a temperature below 15° C. (59° F.). Draw off and reject the lower aqueous layer, and then transfer the ether-layer into a tared beaker. Add 5 Cc. more of ether to the separator, rinse carefully, and add the rinsings to the tared beaker, and entirely evaporate the ether at a moderate heat on a water-bath. Then dry the beaker in an air-bath at 120° C. (248° F.) for half an hour, cool, and weigh. Replace the beaker in the air-bath and heat again at the same temperature for half an hour, cool, and weigh, repeating until the weight is constant. Multiply the weight of the residue by 20, to obtain the weight in grammes of anhydrous ether-soluble alkaloids contained in *one hundred cubic centimeters* of the Fluidextract of Cinchona." U. S.

"Red Cinchona Bark, in No. 60 powder, 20 ounces (Imperial) or 640 grammes; Hydrochloric Acid, 5 *fl. drachms* (Imp. meas.) or 20 cubic centimetres; Glycerin, 2½ *fl. ounces* (Imp. meas.) or 80 cubic centimetres; Alcohol (90 per cent.), Distilled Water, of each *a sufficient quantity*. Mix the Red Cinchona Bark with *five pints* (Imp. meas.) or three thousand two hundred cubic centimetres of the Distilled Water, to which the Hydrochloric Acid and Glycerin have been added; set aside in a covered vessel for forty-eight hours, stirring frequently; transfer to a percolator; when the liquid ceases to pass, and the contents of the percolator have been properly packed, continue the percolation with Distilled Water until *fifteen pints* (Imp. meas.) or nine thousand six hundred cubic centimetres of liquid have passed, or until that which is passing has ceased to give a precipitate on the addition to it of an excess of *solution of potassium hydroxide*. Evaporate the percolate in a porcelain or enamelled iron vessel at a temperature not exceeding 180° F. (82.2° C.), until it is reduced to *twenty fluid ounces* (Imp. meas.) or six hundred and forty cubic centimetres of liquid.

Determine the proportion of alkaloids in the liquid product by the following analytical process:

Put 5 cubic centimetres of the liquid, together with 25 cubic centimetres of *water*, into a stoppered glass separator; add 30 cubic centimetres of *benzolated amylic alcohol*¹ and 15 cubic centimetres of *solution of potassium hydroxide*; shake them together thoroughly and repeatedly; allow them to remain at rest until the spirituous solution of the alkaloids shall have separated and formed a distinct stratum over the dark-colored alkaline liquid. Run off the latter by the stop-cock into another separator; agitate it thoroughly with 30 cubic centimetres of *benzolated amylic alcohol*; allow the liquids to separate; draw off and reject the lower layer; add the alcoholic layer to the liquid in the first separator; wash the mixture with a little *water*; agitate thoroughly with 30 cubic centimetres of a warm mixture of 1 volume of *diluted hydrochloric acid* and 5 volumes of *water*; allow the liquids to separate; draw off the lower acid layer into another separator; agitate the alcoholic layer with a second quantity of 30 cubic centimetres of the mixture of *water* and *diluted hydrochloric acid*; when separated draw this off into the other portion of acid liquid; to the mixture add 10 cubic centimetres of *chloroform* and sufficient *solution of ammonia* to impart a strongly alkaline reaction; shake thoroughly; allow the liquids to separate; draw off the lower chloroformic layer into a weighed dish; repeat the agitation and separation with two successive quantities of 10 cubic centimetres of *chloroform*, and add the chloroformic liquids to that in the dish. Allow the *chloroform* to evaporate slowly; dry the

¹ Made by mixing together three measures of benzol and one measure of amylic alcohol.

residue in the dish at a temperature of about 230° F. (110° C.). The weight of the dish and its contents, after deducting the known weight of the dish, will give that of the alkaloids.

Having thus ascertained the alkaloidal strength of the *twenty fluid ounces* (Imp. meas.) or 640 cubic centimetres of liquid product, every volume of it containing 5 grammes of total alkaloids is first to be brought to 85 cubic centimetres either by evaporation or, if necessary, by dilution with Distilled Water, then a volume of 12.5 cubic centimetres of the Alcohol is to be added, and the final adjustment of the volume to 100 cubic centimetres is to be effected by the addition of Distilled Water. The finished Liquid Extract will thus contain 5 grammes of the alkaloids of the bark in every 100 cubic centimetres, or 5 grains in 110 minims." *Br.*

Of these two formulas, the first is decidedly preferable. It is based upon that of Alfred B. Taylor of Philadelphia (*A. J. P.*, Jan, 1865). The British Pharmacopœia uses acidulated water with glycerin as a solvent, while it adds alcohol to the liquid to preserve it. In the U. S. process a mixture of alcohol, water and glycerin is used as the menstruum. Now, it is well known that cinchona cannot be properly exhausted by the British solvent; and, though by its use as a menstruum the resin and cinchonic red are mainly left behind, so also is a considerable proportion of the alkaloids. By using alcohol, water and glycerin, the U. S. Pharmacopœia extracts all the virtues of the bark, though it may also take up some of the resin and cinchonic red. The process of the British Pharmacopœia yields a preparation which would be more appropriately termed an "alkaloidal solution of cinchona." The U. S. fluidextract, like others of its class, is a preparation which represents all of the soluble active constituents of cinchona; the British liquid extract, although an improvement on the former process, is simply a "preserved infusion" made by prolonged evaporation; the improvement consists in the addition of acid to the menstruum and the assaying of a portion of the evaporated percolate by a process similar to that adopted by the British Pharmacopœia for cinchona and making the finished product contain 5 per cent. of mixed alkaloids; thus any imperfections in the manipulation are overcome by the check of the assay.¹ The U. S. fluidextract of cinchona is a moderately thin, dark reddish brown, translucent fluid, of a bitter, astringent taste.

Dose, five to twenty minims (0.3 to 1.3 Cc.).

¹ *Liquid Extract of Cinchona* (simplified).—Take of Quinine 75 grains, Cinchonidine 35 grains, Cinchonine 20 grains, Hydrochloric Acid 40 minims, Glycerin 5 fluidrachms, Alcohol 1 fluidrachm. Dissolve the alkaloids in the alcohol and glycerin mixed with 5 fluidounces of water, add the acid, agitate until dissolved, and add sufficient water to make 8 fluidounces. If the color and flavor of the bark are desired, add 60 grains of Red Cinchona in powder to the solution, allow it to stand 24 hours, then filter.

FLUIDEXTRACTUM COCÆ. U. S. (Br.)

FLUIDEXTRACT OF COCA [Extractum

Cocæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm cō'cæ)

Extractum Cocæ Liquidum, Br.; Liquid Extract of Coca; Fluidextract of Erythroxylon; Extrait liquide de Coca, *Fr.*; Flüssiges Cocablätterextract, Flüssiges Cocaextrakt, *G.*

* "Coca, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluid-ounces, 6½ fluidrachms]. Moisten the powder with *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Coca is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of ether-soluble alkaloids in the remainder of the liquid, and add to this enough Diluted Alcohol to make each *one hundred cubic centimeters* of the Fluidextract contain 0.5 Gm. of ether-soluble alkaloids from Coca." *U. S.*

Assay of Fluidextract of Coca. *U. S.* (8th Rev.).—"Fluidextract of Coca, *ten cubic centimeters*; Ammonia Water, Ether, Distilled Water, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., or Iod eosin T.S., each, a *sufficient quantity*. Transfer 10 Cc. of Fluidextract of Coca by means of a graduated pipette to a separator, add 25 Cc. of ether, and then 2 Cc. of ammonia water, shaking together for one minute. When the liquids have completely separated, draw off the lower aqueous layer into a second separator, and to this add 20 Cc. more of ether, and repeat the shaking for one minute. Draw off and reject the lower aqueous layer from the second separator, and add the ether-layer to the first separator. To this separator now add 5 Cc. of normal sulphuric acid V.S. and 5 Cc. of distilled water, and shake it well for one or two minutes. After the liquids have separated, draw off the lower aqueous layer into the other separator, and repeat the extraction in the first separator with 9 Cc. of distilled water and 1 Cc. of normal sulphuric acid V.S., shaking the liquids for one minute, and separating as before. Add the aqueous solution to the other separator, and reject the

ether. Now add to the combined acid liquids 20 Cc. of ether, a small piece of red limbus paper, and sufficient ammonia water to render the mixture distinctly alkaline, and shake the liquids for one or two minutes. Draw off the separated aqueous layer into the other separator and the ether-layer into a beaker. Repeat the extraction of the aqueous layer in the other separator with two portions (15 Cc. each) of ether, and add the resulting ether-solutions to the beaker. Now evaporate the ether from the beaker, and, when dry, add to it 5 Cc. of tenth-normal sulphuric acid V.S., and stir until the alkaloidal residue is dissolved. Then add 5 drops of hematoxylin T.S. or iodeosin T.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 5 (the 5 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.03, and this product by 10, to obtain the weight in grammes of ether-soluble alkaloids contained in *one hundred cubic centimeters* of the Fluidextract of Coca." U. S.

"Coca Leaves, in No. 20 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (60 per cent.), a sufficient quantity. Mix the powdered Coca Leaves with two pints (Imp. meas.) or two thousand cubic centimetres of the Alcohol; set aside in a closed vessel for forty-eight hours; transfer to a percolator; when the fluid ceases to pass, continue the percolation with more of the Alcohol until the Coca Leaves are exhausted. Reserve the first fifteen fluid ounces (Imp. meas.) or seven hundred and fifty cubic centimetres of the percolate; evaporate the remainder, at a temperature below 176° F. (80° C.), to the consistence of a soft extract; dissolve this in the reserved portion; add enough of the Alcohol to produce twenty fluid ounces (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." Br.

This fluidextract is one of the most useful of the preparations of coca. L. F. Kebler prefers as a menstruum 65 per cent. alcohol and No. 60 powder in making this fluidextract. (*Proc. A. Ph. A.*, 1895, 339; see also *A. J. P.*, 1896, 609; *P. J.*, 1896, 306.) It is of a dark greenish-brown color, of an agreeable tea-like taste, but with little odor.

Dose, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.).

Off. Prep.—Vinum Cocæ, U. S.

FLUIDEXTRACTUM COLCHICI SEMINIS. U. S.

FLUIDEXTRACT OF COLCHICUM SEED
[Extractum Colchici Seminis Fluidum, Pharm. 1890]
(flŭ-ŭd-ĕx-trăĕ-tŭm cŏl'ĕh'ĭ-sĕm'ĭ-nis)

Extrait liquide de Semences de Colchique, Fr.;
Flüssiges Zeitlosensamenextrakt, G.

* "Colchicum Seed, in No. 50 powder, one thousand grammes [or 35 ounces av., 120

grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water, and having moistened the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Colchicum Seed is exhausted. Reserve the first seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay ten cubic centimeters of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of colchicine in the remainder of the liquid, and add to this enough menstruum to make each one hundred cubic centimeters of the Fluidextract contain 0.5 Gm. of colchicine." U. S.

Assay of Fluidextract of Colchicum Seed. U. S. (8th Rev.)—"Fluidextract of Colchicum Seed, ten cubic centimeters; Ether, Chloroform, Alcohol, Ammonia Water, Distilled Water, each, a sufficient quantity. Measure into a separator 10 Cc. of Fluidextract of Colchicum Seed, add 1 Cc. of ammonia water, and shake out the alkaloid with three successive portions, 15, 15, and 10 Cc., of chloroform. Collect the chloroformic solutions in a beaker or dish, and evaporate it nearly to dryness by applying a very gentle heat. Dissolve the residue in 10 Cc. of ether, add 5 Cc. of water, stir well, and heat gently until the ether is evaporated. After cooling, filter the aqueous solution into a small separator, retaining the insoluble matter as much as possible in the beaker or dish. Redissolve the residue in a little ether, add 5 Cc. of water, and proceed as before. Wash the container and filter with a little water, and shake the aqueous solution well for one minute with 15 Cc. of chloroform. Draw off the chloroform, after perfect separation, into a tared flask, and again shake out the aqueous liquid, successively, with three portions of 10 Cc. each of chloroform, collecting these solutions in the tared flask. Evaporate the chloroform completely; dissolve the residue in a little alcohol, evaporate the latter, redissolve it in alcohol, evaporate the alcohol as before, and dry the residue at 100° C. (212° F.), until the weight, after cooling in a desiccator, remains constant. Multiply the weight of the residue by 10, to obtain the weight in

grammes of colchicine contained in *one hundred cubic centimeters* of the Fluidextract of Colchicum Seed." U. S.

The use of glycerin in this fluidextract (U. S. P. 1870) was even more objectionable than in that of the root, as the fixed oil contained in the seeds was always thrown out of solution, and was usually found floating on the fluidextract, rendering the preparation unsightly. L. I. Morris (*A. J. P.*, 1881, 7) believes that it is unnecessary to grind the colchicum seeds, and that if the whole seeds are digested with diluted alcohol at 80° C. (176° F.) the colchicine is easily extracted.

Dose, from two to eight minims (0.12 to 0.5 Cc.).

Off. Prep.—*Vinum Colchici Seminis, U. S.*

FLUIDEXTRACTUM CONII. U. S.

FLUIDEXTRACT OF CONIUM [Extractum
Conii Fluidum, Pharm. 1890]

(flâ-îd-êx-trâc-tûm cō-nî')

Extractum Conii Fructus Fluidum, U. S. 1870;
Fluid Extract of Conium Seed, or Hemlock Fruit;
Extrait liquide de semence (fruit) de Ciguë, Fr.;
Flüssiges Schierlingsfruchtextract, G.

* "Conium (fruit) in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *twenty cubic centimeters* [or 325 minims]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Acetic Acid with *nine hundred and eighty cubic centimeters* [or 33 fluidounces, 66 minims] of Diluted Alcohol, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding first the remainder of the menstruum and then Diluted Alcohol, until the Conium is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of coniine in the remainder of the liquid, and add to this enough Diluted Alcohol to make each *one hundred cubic centimeters* of the Fluidextract contain 0.45 Gm. of coniine." U. S.

Assay of Fluidextract of Conium. U. S. (8th Rev.)—"Fluidextract of Conium, *ten cubic centimeters*; Ether, Alcohol, Absolute Alcohol, Ammonia Water, Normal Sulphuric Acid V.S.,

Sodium Carbonate T.S., Hydrochloric Acid Solution (5 percent. HCl), Distilled Water, each, *a sufficient quantity*. Transfer 10 Cc. of Fluidextract of Conium by means of a graduated pipette to an evaporating dish containing a little clean sand, and evaporate it to dryness at a gentle heat. Mix the sand uniformly with the extract and transfer it to an Erlenmeyer flask of about 200 Cc. capacity, rinse the dish with 100 Cc. of a mixture of ether 100 Cc., alcohol 7 Cc., and ammonia water 3 Cc., added in portions, and transfer the rinsings to the flask. Insert the stopper securely and shake the flask at intervals during one hour. Decant 50 Cc. of the liquid (representing 5 Cc. of the Fluidextract of Conium) into a beaker, and add sufficient normal sulphuric acid V.S. to produce a distinctly acid reaction. Evaporate the ether at a gentle heat by the aid of a water-bath; then add 15 Cc. of absolute alcohol, and set the beaker aside in a cool place for two hours to allow the ammonium sulphate to deposit. Filter the liquid; wash the residue and filter with a little absolute alcohol, and add the washings to the filtrate; neutralize any excessive amount of acid with sodium carbonate T.S., being careful to retain a slight acidity. Concentrate the liquid to 3 Cc. by the aid of a gentle heat on a water-bath, add 3 Cc. of distilled water and 2 drops of normal sulphuric acid V.S. Add 15 Cc. of ether to remove traces of fatty matter, pour off the ether-solution, and repeat the washing. Then transfer the acid liquid to a separator, introduce a small piece of red litmus paper, and add sufficient sodium carbonate T.S. to render the liquid slightly alkaline; then shake out with successive portions of 15, 10, and 10 Cc. of ether. To the combined ether-solutions in a tared beaker add, drop by drop, sufficient hydrochloric acid solution (5 percent.) to insure an excess of acid, and then evaporate the ether by a gentle heat on a water-bath. Remove the excess of hydrochloric acid by adding to the residue 3 Cc. of alcohol and heating gently to evaporate the liquid, repeat this operation once, and dry the residue at a temperature not exceeding 60° C. (140° F.) until the weight, after cooling in a desiccator, remains constant. Multiply the weight of the residue by 0.777, and the product by 20, to obtain the weight in grammes of coniine contained in *one hundred cubic centimeters* of the Fluidextract of Conium." U. S.

The fluidextract of conium of the U. S. Pharmacopœia of 1860 was prepared from the leaves, and was, therefore, of necessity a very uncertain, if not for the most part inert, preparation. The alkaloid coniine is contained in very unequal proportions in the fresh leaves, and is so very volatile and destructible that in the dried leaves it may be altogether wanting. Wm. Manlius Smith (*A. J. P.*, xl. 459), as the result of an elaborate investigation, found that the immature fruits of conium are not only richer in the alkaloids than are the leaves, but are less variable in the proportion they contain,

and have the conine in them in such form that drying does not dissipate it. The superiority of the fluidextract of conium seed over the same preparation of the leaves was shown by Smith, and has been since abundantly confirmed by experience. The revisers of the U. S. Pharmacopœia of 1870 acted very wisely in abandoning the old for the new preparation.

The present fluidextract is a dark brownish-green liquid having the mouse-urine odor and emitting a still stronger conium odor on the addition of potassium hydroxide; any sample which fails to do this should be rejected as wanting in the alkaloid. Smith found sixteen minims (1 Cc.) of a fluidextract of the seed prepared by Squibb to produce violent symptoms. L. Wheeler, however, took thirty minims (1.8 Cc.) without experiencing any result (B. M. S. J., June, 1870), but dangerous results have followed from the administration of much smaller doses.

Dose, three to five minims (0.2 to 0.3 Cc.), increased *pro re nata*.

FLUIDEXTRACTUM CONVALLARIÆ. U. S.

FLUIDEXTRACT OF CONVALLARIA [Extractum
Convallariæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm côn-văl-lă'rî-æ)

Fluidextract of Lily of the Valley; Extrait liquide de Muguet, Fr.; Flüssiges Maiblumenwurzelextrakt, G.

* "Convallaria, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, until the Convallaria is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract thoroughly represents the activity of convallaria.

Dose, from five to fifteen minims (0.3 to 0.9 Cc.).

FLUIDEXTRACTUM CUBEBÆ. U. S.

FLUIDEXTRACT OF CUBEB [Extractum
Cubebæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm cù-bé'bæ)

Extrait liquide de Cubèbe, Fr.; Flüssiges Kubebenextrakt, G.

* "Cubeb, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Cubeb is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

Notwithstanding the fact that the oleoresin of cubeb thoroughly represents in a concentrated liquid form all the virtues of this drug, the alcoholic fluidextract is a useful preparation; it permits the administration of cubeb in aqueous or hydro-alcoholic mixtures where the oleoresin would not be admissible except in emulsion. It is a dark olive, translucent fluid, with the sensible properties of the drug.

Dose, from ten to forty minims (0.6 to 2.5 Cc.).

FLUIDEXTRACTUM CYPRIPEIDII. U. S.

FLUIDEXTRACT OF CYPRIPEIDIUM [Extractum
Cypripedii Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm cÿp-rî-pé'dî-i)

Fluidextract of Lady's Slipper; Extrait liquide de Cypripède jaune, Fr.; Flüssiges Gelbfrauenschuhextrakt, G.

* "Cypripedium, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted

Alcohol, until the Cypripedium is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This fluidextract well represents the drug, although its use is at present very limited. It is very dark reddish brown in color.

Dose, fifteen minims (0.9 Cc.).

FLUIDEXTRACTUM DIGITALIS. U. S.

FLUIDEXTRACT OF DIGITALIS [Extractum Digitalis Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm dig-i-tă'lis)

Extrait liquide de Digitale, *Fr.*; Flüssiges Fingerhutkrautextrakt, Flüssiges Digitalisextrakt, *G.*

* “Digitalis, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Digitalis is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This fluidextract is greenish black in color, and represents the drug thoroughly.

Dose, one to two minims (0.06 to 0.12 Cc.).

Off. Prep.—Extractum Digitalis, *U. S.*

FLUIDEXTRACTUM ERGOTÆ. U. S. (Br.)

FLUIDEXTRACT OF ERGOT [Extractum Ergotæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm êr'gô-tæ)

* “Ergot, recently ground and in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *twenty cubic centi-*

meters [or 325 minims]; Diluted Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Acetic Acid with *nine hundred and eighty cubic centimeters* [or 33 fluidounces, 66 minims] of Diluted Alcohol, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding first the remainder of the menstruum and then Diluted Alcohol, until the Ergot is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

“Ergot, crushed, 20 ounces (Imperial) or 400 grammes; Distilled Water, 7½ pints (Imp. meas.) or 3000 cubic centimetres; Alcohol (90 per cent.), 7½ fl. ounces (Imp. meas.) or 150 cubic centimetres. Digest the crushed Ergot in five pints (Imp. meas.) or two thousand cubic centimetres of the Distilled Water for twelve hours; draw off the infusion; repeat the digestion with the remainder of the Distilled Water; press; strain; evaporate the liquid to fourteen fluid ounces (Imp. meas.) or two hundred and eighty cubic centimetres; when cold, add the Alcohol; set aside for an hour; filter. The product should measure twenty fluid ounces (Imp. meas.) or four hundred cubic centimetres.” *Br.*

This fluidextract was first suggested by Joseph Laidley of Richmond, Va., but the process has since been much modified. The improvement first suggested by Procter, of adding an acid to the menstruum to fix the alkaloids, and the selection of the proper menstruum, placed this important preparation at once on a permanent footing, and his original formula, published in 1857, and made official in 1860, is practically that now official, notwithstanding the numerous changes of views concerning the active constituents of ergot. Practical experience has shown that it is not only a reliable preparation, but also, if carefully made, a permanent one. The use of glycerin in the menstruum is of no benefit whatever; as an addition, diluted hydrochloric has been replaced by acetic acid for fixing alkaloids, which makes the present fluidextract identical with Procter's original formula. (See *Ergota*.) Diluted alcohol dissolves all the active matter of ergot, leaving its oil behind, and the tincture first obtained, holding most of the active prin-

ciples, is reserved without concentration. In the British process the prolonged digestion and evaporation must act disadvantageously upon principles which are known to be very easily affected by heat and exposure. Bernagan and Burkhart have devised a process in which the fluidextract contains 5 per cent. of sodium chloride. The advantages are not apparent. (*Ap. Ztg.*, 1895, 309.)

The U. S. fluidextract of ergot is a clear, very dark reddish-brown liquid, having the taste of ergot, but without its fishy odor, owing to the neutralization of the trimethylamine, upon which that odor depends. On the addition, however, of solution of potassium hydroxide, the odor is strongly developed, and the alkaloid escapes so largely that, if hydrochloric acid be held near it, a cloud of trimethylamine chloride will be perceived. This may be considered as a good test of the efficiency of the preparation, for, though the virtues of ergot do not depend on its volatile alkaloid, yet if this be retained in the fluidextract there can be little doubt that the other more fixed principles will be retained also. The preparation is an active one, but in large doses it is more apt to produce nausea than is the simple extract.

Dose, from half a fluidrachm to half a fluidounce (1.8 to 15 Cc.).

Off. Prep.—Vinum Ergotæ, U. S.

FLUIDEXTRACTUM ERIODICTYI. U. S.

FLUIDEXTRACT OF ERIODICTYON [Extractum Eriodictyi Fluidum, Pharm. 1890]

(flû-jd-êx-trăc-tûm êr-i-ô-dic-tÿ-i)

Fluidextract of Yerba Santa; Extrait liquide d'Eriodictyon, *Fr.*; Flüssiges Eriodictyonextrakt, *G.*

* "Eriodictyon, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Eriodictyon is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract;

dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract¹ has a dark brownish-green color, and has proven a valuable addition.

Dose, from fifteen minims to a fluidrachm (0.9 to 3.75 Cc.).

FLUIDEXTRACTUM EUCALYPTI. U. S.

FLUIDEXTRACT OF EUCALYPTUS [Extractum Eucalypti Fluidum, Pharm. 1890]

(flû-jd-êx-trăc-tûm eû-ca-lyp-tÿ-i)

Extrait liquide d'Eucalyptus, *Fr.*; Flüssiges Eucalyptusextrakt, *G.*

* "Eucalyptus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Eucalyptus is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract well represents the drug, and is of a dark greenish-brown color, having the peculiar odor and taste of eucalyptus very strongly developed, but in effectiveness it is much inferior to the volatile oil.

Dose, from ten to thirty minims (0.6 to 1.8 Cc.).

¹ *Aromatic Fluidextract of Yerba Santa* (Edel's process).—Take of fluidextract of yerba santa, 2 fluidounces; oil of cloves, 32 drops; oil of orange, 16 drops; oil of saffrafras, 16 drops; alcohol, 3 fluidounces; solution of potassium hydroxide, 12 fluidrachms; compound fluidextract of cardamom, 4 fluidrachms; water, 4 fluidounces; glycerin, purified talc, of each a sufficient quantity. The fluidextracts and oils are mixed, the solution of potassium hydroxide and water added, then some talc, and finally the alcohol, when the mixture is filtered, returning the first filtrate until it passes clear. Sufficient glycerin is then added to the filtrate to make one pint. The preparation is readily miscible with water, elixirs, or syrups. This fluidextract (so called) is intended for making a palatable Aromatic Syrup of Yerba Santa. (*Proc. A. Ph. A.*, 1897, 423.)

FLUIDEXTRACTUM EUONYMI. U. S.

FLUIDEXTRACT OF EUONYMUS

(flû-jd-êx-trăc'tûm eû-ôn'y-mî)

Fluidextract of Wahoo; Extrait liquide d'Ecorce de Fusain Américain, *Fr.*; Flüssiges Spilbaumrindenextrakt, *G.*

* "Euonymus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Euonymus is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

Dose, as a laxative, five to fifteen minims (0.3 to 0.9 Cc.); as a purgative, one fluidrachm (3.75 Cc.).

Off. Prep.—Extractum Euonymi, U. S.

FLUIDEXTRACTUM EUPATORII. U. S.

FLUIDEXTRACT OF EUPATORIUM [Extractum Eupatorii Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm eû-pă-tô'ri-i)

Fluidextract of Boneset, Fluidextract of Thoroughwort; Extrait liquide d'Eupatoire perfoliée, *Fr.*; Flüssiges Durchwachsenener-Wasserhanfextrakt, Flüssiges Durchwachsenstosenextrakt, *G.*

* "Eupatorium, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Eupatorium is exhausted. Reserve

the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract will have but a limited use, although it well represents the drug, since boneset is chiefly employed in domestic medicine. It is of a dark greenish-brown color.

Dose, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.).

FLUIDEXTRACTUM FRANGULÆ.

U. S.

FLUIDEXTRACT OF FRANGULA [Extractum Frangulæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm frân'gû-læ)

Extrait liquide d'Ecorce de Bourdaine, *Fr.*; Extractum Frangulæ fluidum, *P. G.*; Faulbaum-Fluidextrakt, Flüssiges Faulbaumrindenextrakt, *G.*

* "Frangula, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Frangula is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This is a fluidextract which has been quite largely used in this country. It is intended to be a laxative, but it is frequently disappointing, as the drug is rarely to be obtained of uniformly good quality. The fluidextract is of a dark reddish-brown color.¹

Dose, ten to twenty minims (0.6 to 1.3 Cc.).

¹ Sweet Fluid Extract of Buckthorn (Edel's process).—Fld. extr. buckthorn, 16 fl. oz.; solution of potassa, 1 fl. dr.; solution of liquorice (N. F.), 2 fl. oz.; saccharin, 1 dr. Take 3 fluidounces of the fluidextract, reduce by evaporation to half a fluidounce, dissolve in the rest of the fluidextract, add the solution of potassa, saccharin, and liquorice. The resulting product is a permanent sweet fluidextract. (*Proc. A. Ph. A.*, 1897, 423.)

FLUIDEXTRACTUM GELSEMII. U. S.

FLUIDEXTRACT OF GELSEMIUM [Extractum
Gelsemii Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm gêl-sêm'î-i)

Extrait liquide de Jasmin jaune ou Gelsemium, Fr.; Flüssiges Gelber Jasminextrakt, Flüssiges Gelsemiumextrakt, G.

* "Gelsemium, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Gelsemium is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This is identical with the fluidextract formerly official, which has proved very useful. It is of a dark reddish-brown color.

Dose, from two to three minims (0.12 to 0.2 Cc.).

FLUIDEXTRACTUM GENTIANÆ. U. S.

FLUIDEXTRACT OF GENTIAN [Extractum
Gentianæ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm gên-ti-ă'ne)

Extrait liquide de Gentiane, Fr.; Flüssiges Enzianextrakt, G.

* "Gentian, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Gentian is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough

Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This is a translucent, reddish-brown fluid, with the odor and taste of the root. It may be questionable whether it was needed, though it has the advantage that we may obtain from it the tonic effects of the drug with less alcohol than in an equivalent quantity of the tincture, and pharmaceutically it affords a convenient method of giving to mixtures the tonic properties of gentian when required.

Dose, from ten to thirty minims (0.6 to 1.8 Cc.).

FLUIDEXTRACTUM GERANII. U. S.

FLUIDEXTRACT OF GERANIUM [Extractum
Geranii Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm gê-ră'nî-i)

Extrait liquide de Géranium maculé, Extrait liquide de Bec de Grue tacheté, Fr.; Flüssiges Fleckenstorchschnabelextrakt, G.

* "Geranium, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol, and *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water, until the Geranium is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

The quantity of glycerin was greatly diminished in this fluidextract in the U. S. P. 1890, and the process is now unobjectionable. It is a dark reddish-brown liquid, having little odor and a very astringent taste. For Stolz's process, see *Registered Pharmacist*, 1893, 253.

Dose, from thirty minims to a fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM GLYCYRRHIZÆ.

U. S. (Br.)

FLUIDEXTRACT OF GLYCYRRHIZA: [Extractum Glycyrrhizæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc-tûm glÿc-yŕ-rhî-zæ)

Extractum Glycyrrhizæ Liquidum, Br.: Liquid Extract of Liquorice; Fluidextract of Licorice or Liquorice; Extrait liquide de Régilisse, Fr.; Flüssiges Süßholzwurzel-extrakt, G.

* "Glycyrrhiza, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]; Ammonia Water, fifty cubic centimeters [or 1 fluidounce, 331 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Pour four hundred cubic centimeters [or 13 fluidounces, 252 minims] of boiling Water upon the Glycyrrhiza, contained in a suitable vessel, and allow it to stand for one hour. Pack the moistened powder loosely in a metallic percolator, pour boiling Water upon it, and allow the percolation to proceed, supplying boiling Water until the Glycyrrhiza is exhausted. Evaporate the percolate at a moderate heat, until it measures four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims], and, when cool, add four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of Alcohol, mix well and set it aside for three days. After filtering the liquid, distil it until five hundred cubic centimeters [or 16 fluidounces, 435 minims] of distillate have been obtained; transfer the liquid in the still to a suitable container, add the Glycerin, Ammonia Water, and two hundred cubic centimeters [or 6 fluidounces, 366 minims] of Alcohol. Finally, add sufficient Water to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S.

"Liquorice Root, in No. 20 powder, 20 ounces (Imperial) or 1000 grammes; Distilled Water, 5 pints (Imp. meas.) or 5 litres; Alcohol (90 per cent.), a sufficient quantity. Mix the Liquorice Root with half of the Distilled Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Distilled Water and set aside for six hours; strain; press; mix the strained liquids; heat to 212° F. (100° C.); strain through flannel; evaporate until the fluid has acquired, when cold, a specific gravity of 1.200; add to this one-fourth of its volume of the Alcohol; let the mixture stand for twelve hours; filter." Br.

¹ **Extractum Glycyrrhizæ Spirituosum, Br. Add.** Spirituous Extract of Liquorice.—"Extract of Liquorice, 10 ounces (Imperial) or 500 grammes; Alcohol (90 per cent.), 5 fl. ounces (Imp. meas.) or 250 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Extract of Liquorice with enough Distilled Water to form a liquid; add the Alcohol; then add enough Distilled Water to produce a well-mixed bulk of one pint (or one thousand cubic centimetres); filter if necessary." Br. Add.

Dose, one-half to one fluidrachm (1.8 to 3.75 Cc.).

The process for this fluidextract was materially changed in the U. S. P. (8th Rev.). The former processes, while making stable fluid-extracts of good appearance, were deficient in not providing for the removal of the acrid, oily constituent found in licorice root; the present process overcomes this difficulty by exhausting the coarsely powdered root with boiling water, concentrating the infusions, adding alcohol to precipitate inert constituents, and filtering; the filtrate is distilled to recover the excess of alcohol, and glycerin, ammonia water and alcohol added to bring the measure to the required standard. This process is essentially that recommended by A. R. L. Dohme. The British formula for the liquid extract has several inconvenient manipulative features, such as the repeated macerations and expressions, evaporating to a certain specific gravity, etc. (See *Mont. Pharm. Journ.*, 1893, 147; *P. J.*, 1898, 188.) This preparation is now very largely used as an adjuvant, and for disguising the bitter taste of quinine, which should be added to the preparation of licorice just before the dose is taken. It is a very convenient form for using licorice, the objections to the former fluidextracts of the root having been the slight acidity and the presence of too much alcohol. Not only does the ammonia render the glycyrrhizin soluble, thus materially adding to the power and sweetness of the fluid-extract, but it also greatly lessens the acidity. It is a very dark reddish-brown liquid, having the well known sweet taste of licorice, and froths when shaken with water. A syrup of licorice may be made by adding two parts of fluidextract to fourteen parts of simple syrup. An elixir containing licorice (*Elixir Adjuvans*) was made official in the U. S. P. 8th Rev.

Used as a vehicle only.

Off. Prep.—Elixir Adjuvans, U. S.; Mistura Sennæ Composita, Br.; Syrupus Sarsaparillæ Compositus, U. S.; Tinctura Aloes, Br.

FLUIDEXTRACTUM GRANATI. U. S.

FLUIDEXTRACT OF POMEGRANATE

(flû-jd-êx-trăc-tûm gră-nă'tî)

Fluidextract of Pomegranate Root Bark: Extrait liquide d'Ecorce de Balaustral, Extrait liquide d'Ecorce de Grenadier, Fr.; Flüssiges Granatwurzelrinden-extrakt, G.

* "Granatum, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of Diluted Alcohol, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate

the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Pomégranate is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract was admitted to the U. S. Pharmacopœia (8th Revision) for the first time; it well represents the virtues of pomégranate.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM GRINDELIAE. U. S. (Br. Add.)

FLUIDEXTRACT OF GRINDELIA [Extractum
Grindeliæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm grîn-dê'lî-æ)

Extractum Grindeliæ Liquidum, Br. Add., Liquid Extract of Grindelia; *Extrait liqvide de Grindélia, Fr.*; Flüssiges Grindellenextrakt, G.

* "Grindelia, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, until the Grindelia is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath; and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

"Grindelia, in No. 40 powder, 20 ounces (Imperial) or 1000 grammes; Sodium Bicarbonate, 2 ounces (Imp. meas.) or 100 grammes; Distilled Water, 10 fl. ounces (Imp. meas.) or

500 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Moisten the Grindelia with *eight fluid ounces* (Imp. meas.) or four hundred cubic centimetres of the Alcohol; macerate in a closed vessel for twenty-four hours; pack the moistened powder in a percolator, and add enough of the Alcohol to saturate it thoroughly; when the liquid begins to drop, close the lower orifice of the percolator; set aside for twenty-four hours, then allow percolation to proceed, gradually adding more of the Alcohol until the Grindelia is exhausted. Remove the alcohol by distillation, and dissolve the residue in the Distilled Water to which the Sodium Bicarbonate has previously been added, and after effervescence ceases add enough Distilled Water to produce *fifteen fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres and then enough of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." Br. Add.

This is a fluidextract which well represents the drug; owing to the large quantity of resinous matter present, it does not mix well with aqueous liquids. The so-called "*alkaline fluid extract of grindelia*" may be made by evaporating one pint of official fluidextract until reduced to twelve fluidounces, making a solution of 180 grains of sodium bicarbonate in four fluidounces of water, adding it slowly to the evaporated fluidextract, and filtering. The fluidextract is a dark brown liquid having the peculiar odor of grindelia.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM GUARANÆ. U. S.

FLUIDEXTRACT OF GUARANA [Extractum
Guaranæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm gua-ră'næ)

Extrait liqvide de Guarana, Fr.; Flüssiges Guaranæextrakt, G.

* "Guarana, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Guarana is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *five cubic centimeters* of

this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of alkaloids contained in the remainder of the liquid; add to this enough Diluted Alcohol to make *one hundred cubic centimeters* of the finished Fluidextract contain 3.5 Gm. of the alkaloids from Guarana." *U. S.*

Assay. *U. S. (8th Rev.)*—"Fluidextract of Guarana, *five cubic centimeters*; Chloroform, Ether, Ammonia Water, Normal Sulphuric Acid V.S., Distilled Water, each, *a sufficient quantity*. Transfer to a separator 5 Cc. of Fluidextract of Guarana, add 15 Cc. of chloroform and 1 Cc. of ammonia water. Shake well and allow the liquid to separate completely. Draw off the chloroform into a beaker. Shake out the fluid remaining in the separator with two additional portions of chloroform of 10 Cc. each, evaporate the combined chloroformic solutions carefully to dryness. Dissolve the alkaloidal residue in a mixture of 2 Cc. of normal sulphuric acid V.S. and 20 Cc. of warm distilled water. Allow it to cool, and filter the solution into a separator, rinse the flask and filter with distilled water, adding the rinsings to the separator, then add 20 Cc. of chloroform and 2 Cc. of ammonia water and shake the separator for one minute. Draw off the chloroform into a tared flask, and repeat the extraction with two portions of 10 Cc. each of chloroform, adding this to the tared flask. Distil off the chloroform, and, when dry, add 2 Cc. of ether, and evaporate this very carefully with the aid of a water-bath (to avoid decrepitation). Dry the residue to a constant weight on the water-bath. Multiply the weight by 20, which will give the weight in grammes of alkaloids contained in *one hundred cubic centimeters* of Fluidextract of Guarana." *U. S.*

This fluidextract is of doubtful utility. The powdered drug itself is portable, not unpleasant to the taste, and is efficient when given diffused in water; nothing is gained by making it into a fluidextract. The fluidextract is of a deep reddish-brown color. (See *Proc. A. Ph. A.*, 1897, 423.)

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

FLUIDEXTRACTUM HAMAMELIDIS FOLIORUM. *U. S. (Br.)*

FLUIDEXTRACT OF HAMAMELIS LEAVES
[Extractum Hamamelidis Fluidum, Pharm. 1890]

(fû-jd-êx-trăc'tûm hăm-ê-mêl'i-dîs fô-lî-ô'rûm)

Extractum Hamamelidis Liquidum, Br.; Liquid Extract of Hamamelis; Fluidextract of Witch-hazel Leaves; *Extrait liquide de Hamamelis, Fr.*; Flüssiges Hamamelisextrakt, *G.*; Extracto líquido de hamamelis, *Sp.*

* "Hamamelis Leaves, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].

Mix the Glycerin with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol and *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol to *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, until the Hamamelis Leaves are exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Hamamelis Leaves, in No. 40 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powdered Hamamelis Leaves with about *eight fluid ounces* (Imp. meas.) or four hundred cubic centimetres of the Alcohol; pack the moistened powder in a percolator, and add sufficient menstruum to saturate it thoroughly; when the liquid begins to drop, close the lower orifice of the percolator; set aside for forty-eight hours; then allow percolation to proceed, gradually adding menstruum until the Hamamelis Leaves are exhausted; reserve the first *seventeen fluid ounces* (Imp. meas.) or eight hundred and fifty cubic centimetres of the percolate; remove the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient menstruum to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.*

This is a fluidextract which well represents the virtues of witchhazel. It has a dark reddish-brown color.

Dose, half a fluidrachm (1.8 Cc.).

Off. Prep.—Unguentum Hamamelidis, *Br.*

FLUIDEXTRACTUM HYDRASTIS. *U. S. (Br.)*

FLUIDEXTRACT OF HYDRASTIS [Extractum Hydrastis Fluidum, Pharm. 1890]

(fû-jd-êx-trăc'tûm hÿ-drăs'tîs)

Extractum Hydrastis Liquidum, Br.; Liquid Extract of Hydrastis; Fluidextract of Golden Seal; *Extrait liquide de Hydrastis, Fr.*; Extractum Hydrastis fluidum, *P. G.*; Hydrastis-Fluidextract; Flüssiges Hydrastisextrakt, *G.*; Estratto di idraste liquido, *It.*; Extracto líquido de hidraste, *Sp.*

* “Hydrastis, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, until the Hydrastis is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of hydrastine in the remainder of the liquid; add to this enough menstruum to make each *one hundred cubic centimeters* of the finished Fluidextract contain 2 Gm. of hydrastine.” U. S.

Assay. U. S. (8th Rev.).—“Fluidextract of Hydrastis, *ten cubic centimeters*; Distilled Water, Potassium Iodide, Ammonia Water, Ether, each, *a sufficient quantity*. Transfer 10 Cc. of Fluidextract of Hydrastis by means of a graduated pipette to a 100 Cc. measuring flask, add 85 Cc. of distilled water in which 2 Gm. of potassium iodide have been previously dissolved, and sufficient water to make 100 Cc., and shake the liquid for several minutes. Then filter 50 Cc. of the liquid into a measuring cylinder and transfer it to a separator. Render the liquid alkaline with ammonia water, add 30 Cc. of ether, and shake the separator at intervals during several minutes. When separated, draw off the aqueous layer into a beaker, and the ether-solution into a tared beaker. Return the aqueous solution to the separator, and shake it with 20 Cc. more of ether for one minute. Draw off and reject the aqueous layer, and run the ether-solution into the tared beaker. Allow the combined ether-solutions to evaporate at a gentle heat, and dry the residue in the beaker to a constant weight on a water-bath. Multiply the weight by 20, which will give the weight in grammes of hydrastine contained in *one hundred cubic centimeters* of Fluidextract of Hydrastis.” U. S.

“Hydrastis Rhizome, in No. 60 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powdered Hydrastis with about *eight fluid ounces* (Imp. meas.) or four hundred cubic centimetres of the Alcohol; pack the damp powder in a percolator; pour on sufficient menstruum to saturate it thoroughly; when the liquid begins to drop, close the lower orifice of the percolator; set aside for forty-eight hours; then allow percolation to proceed, gradually adding menstruum until the Hydrastis is exhausted; reserve the first *seventeen fluid ounces* (Imp. meas.) or eight hundred and fifty cubic centimetres of the percolate; remove the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient menstruum to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract.” Br.

The fluidextract thoroughly represents the drug. It is of a deep brownish-yellow color.

Dose, from fifteen minims to one fluidrachm (0.9 to 3.75 Cc.).

FLUIDEXTRACTUM HYOSCYAMI. U. S.

FLUIDEXTRACT OF HYOSCYAMUS [Extractum Hyoscyami Fluidum, Pharm. 1890]

(flŭ-ŭd-ĕx-trăĕ-tŭm hŭ-ŭs-ĕy-ă-mŭ)

Extrait liqvide de Jusquame, Fr.; Flüssiges Bilsenkrautextrakt, G.

* “Hyoscyamus, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Hyoscyamus is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *fifty cubic centimeters* of this liquid, as directed below; from the results thus obtained, ascertain by calculation the amount of the alkaloids in the remainder of the liquid; add to this enough menstruum to make each *one hundred cubic centi-*

meters of the finished Fluidextract contain 0.075 Gm. of the alkaloids from Hyoscyamus." U. S.

Assay of Fluidextract of Hyoscyamus. U. S. (8th Rev.).—"The method to be employed is identical with that given for Fluidextract of Belladonna Root, using *fifty cubic centimeters* of Fluidextract of Hyoscyamus, instead of the quantity of Fluidextract of Belladonna Root there directed, and multiplying the product by 2 instead of 10." U. S.

This fluidextract was improved in the 1880 revision by abandoning the glycerin directed in the former process. It is of a very dark greenish-brown color. For the medicinal properties, see *Hyoscyamus*.

Dose, from five to ten minims (0.3 to 0.6 Cc.).

Off. Prep.—Extractum Hyoscyami, U. S.

FLUIDEXTRACTUM IPECACUANHÆ.

U. S. (Br.)

FLUIDEXTRACT OF IPECAC [Extractum Ipecacuanhæ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm îp-ê-căc-ûn-â'hæ)

"A Liquid Extract containing 2 to 2½ grains of the alkaloids of Ipecacuanha Root in 110 minims (2 to 2.25 grammes in 100 cubic centimetres)." Br.

Extractum Ipecacuanhæ Liquidum, Br. Liquid Extract of Ipecacuanha; Extrait liquide d'Ipecacuanha, Fr.; Flüssiges Ipecacuanhaextract, G.

* "Ipecac, in No. 80 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Ipecac is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of the alkaloids in the remainder of the liquid; add to this enough menstruum to

make each *one hundred cubic centimeters* of the finished Fluidextract contain 1.75 Gm. of the alkaloids from Ipecac." U. S.

Assay of Fluidextract of Ipecac. U. S. (8th Rev.).—"Fluidextract of Ipecac, *ten cubic centimeters*; Ammonia Water, Ether, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., each, *a sufficient quantity*. Transfer 10 Cc. of Fluidextract of Ipecac by means of a graduated pipette to a porcelain evaporating dish. Evaporate off the alcohol with the aid of a water-bath, and, when almost cool, add 5 Cc. of normal sulphuric acid V.S., and stir the liquid at intervals for three minutes. Filter the liquid into a separator, rinse the dish, and wash the filter successively with 10 Cc. and 5 Cc. of distilled water, and add these liquids to the separator. To the separator add 20 Cc. of ether and a small piece of red litmus paper; render the liquid alkaline with ammonia water and shake the separator for one minute. Draw off the aqueous layer into a beaker, and the ether-layer into another beaker. Return the aqueous solution to the separator, add 10 Cc. more of ether, and shake the liquid, adding the ether-solution to that already in the beaker, and returning the aqueous solution to the separator; repeat the extraction with 10 Cc. more of ether, and then add the ether-layer to that already in the beaker. Allow the combined ether-solutions to evaporate, either spontaneously or with the aid of a water-bath containing warm water, and then add 10 Cc. of tenth-normal sulphuric acid V.S. Stir the liquid carefully with a glass rod to facilitate the solution of the alkaloids, and when these have all dissolved, add 5 drops of hematoxylin T.S. From a graduated burette, add sufficient fiftieth-normal potassium hydroxide V.S. to just cause the yellow color of the solution to turn purple. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 10 (the 10 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0238, and this product by 10, which will give the weight in grammes of alkaloids contained in each *one hundred cubic centimeters* of Fluidextract of Ipecac." U. S.

"Ipecacuanha Root, in No. 20 powder, 1 pound (Imperial) or 800 grammes; Calcium Hydroxide, 700 grains (Imp.) or 80 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Moisten the powdered Ipecacuanha Root with *six fluid ounces* (Imp. meas.) or three hundred cubic centimetres of the Alcohol; pack firmly in a percolator; add more of the Alcohol, and when the liquid begins to drop, close the lower orifice of the percolator; set aside for twenty-four hours. Then percolate slowly until *thirteen and a half fluid ounces* (Imp. meas.) or six hundred and seventy-five cubic centimetres have been collected; reserve this portion. Continue percolation until nothing more is ex-

tracted; drain well. Mix the Lime with the marc; allow them to remain in contact for twenty-four hours; then continue percolation until exhaustion is complete. Recover the alcohol from the last two percolates by distillation; dissolve the residual extract in the reserved portion of percolate.

Determine the proportion of alkaloids in the resulting strong liquid extract by the following analytical process:

Dilute 20 cubic centimetres with an equal bulk of water. Remove the alcohol by the aid of a water-bath; add to the warm solution an excess of solution of lead subacetate. Filter; wash the precipitate with water and add the washings to the filtrate. Remove the excess of lead from the filtrate by precipitation with diluted sulphuric acid; filter; wash the precipitate with water and add the washings to the filtrate. Transfer the filtrate to a separator; add excess of solution of ammonia and agitate with 25 cubic centimetres of chloroform. Separate and set aside the chloroform solution. Twice repeat the agitation with chloroform, and the separation. Mix the chloroform solutions; evaporate; dry at a temperature below 176° F. (80° C.), and weigh the residue of total alkaloids.

From this weight calculate the amount of alkaloids in the bulk of strong liquid extract, and add to the latter sufficient Alcohol (90 per cent.) to produce Liquid Extract of Ipecacuanha containing not less than 2 and not more than 2.25 grammes of alkaloid in 100 cubic centimetres, or from 2 to 2½ grains in 110 minims." *Br.*

The menstruum for the U. S. fluidextract was altered in the U. S. P. 1890 and the proportions then adopted are retained in the Eighth Revision; it was proved by J. U. Lloyd that when alcohol alone is used a portion of emetine escapes solution. On the other hand, it is known that when the menstruum is more aqueous large amounts of the pectinous principles are taken up, and it is very desirable to separate these in order to prevent their appearance as a flocculent precipitate in syrup of ipecac; but efficiency is to be sought for as the first desideratum, and hence a menstruum which will extract the activity and make a fluidextract that will not let fall a bulky precipitate of inert matter has been secured; usually this will not mix with syrup without slight precipitation, but the improved official process for syrup of ipecac should effectually separate any precipitate resulting from the presence of apotheme in the fluidextract.¹ The British liquid extract (1898) is a new preparation and is standardized; the excellent researches of Paul and Cownley on ipecac, and the assay work of Kremel, Keller, and others, undoubtedly prompted the intro-

duction of the process for the liquid extract. (See *Ipecacuanha*.) It will probably be found, however, that the U. S. menstruum is preferable. An *acetic extract of ipecac (dry)* is used in Great Britain; it has been shown that the heating necessary to dry it is injurious to its emetic properties. (*P. J.*, 1895, 158.)

This fluidextract is a thin, dark reddish-brown, transparent liquid, of a bitterish slightly acid taste, but without the nauseous flavor of the root. It is a convenient preparation for adding to expectorant and diaphoretic mixtures, and is used officially principally in preparing the syrup of ipecac.²

Dose, as emetic, fifteen to thirty minims (0.9 to 1.8 Cc.); as an expectorant, one to two minims (0.06 to 0.12 Cc.).

Off. Prep.—Acetum Ipecacuanhæ, *Br.*; Mistura Rhei et Sodæ, *U. S.*; Syrupus Ipecacuanhæ, *U. S.*; Tinctura Ipecacuanhæ et Opii, *U. S.*; Vinum Ipecacuanhæ, *U. S.*, *Br.*

FLUIDEXTRACTUM KRAMERIE. U. S.

FLUIDEXTRACT OF KRAMERIA [Extractum
Krameria Fluidum, Pharm. 1890]

(*kū-īd-ēx-trăc'tūm krā-mē'ri-æ*)

Fluidextract of Rhatany: *Extrait Liquide de Ratanhia, Br.*; Flüssiges Ratanhiaextract, *Ratanhiawurzel-fluidextract, G.*

* "Krameria, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical glass percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Krameria is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This process does not differ essentially from that formerly official except in the absence of glycerin from the menstruum; the fluidextract well represents the root, and has a deep red color and a very astringent taste.

Dose, from ten minims to a fluidrachm (0.6 to 3.75 Cc.).

Off. Prep.—Syrupus Krameria, *U. S.*

¹ R. Rother recommends alcohol for a menstruum and the use of magnesia, and the percolation of the finely powdered ipecac upon what he calls the disc principle. (*D. C.*, 1886, p. 4.)

² For discussion of the alkaloidal strength of ipecac and its fluidextract, by H. W. Snow, see *Ph. Era*, 1887.

FLUIDEXTRACTUM LAPPÆ. U. S.

FLUIDEXTRACT OF LAPPA [Extractum
Lappæ Fluidum, Pharm. 1890]
(lāp-īd-ēx-trăc'tūm lăp'pæ)

Fluidextract of Burdock Root; Extrait liquide de Bardane, Fr.; Flüssiges Klettenwurzelextrakt, G.

* "Lappa, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Lappa is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

The official fluidextract of burdock is of a dark brownish-red color.

Dose, thirty to sixty minims (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM LEPTANDRÆ. U. S.

FLUIDEXTRACT OF LEPTANDRA [Extractum
Leptandræ Fluidum, Pharm. 1890]
(lāp-īd-ēx-trăc'tūm lēp-tăn'dræ)

Fluidextract of Culver's Root; Extrait liquide de Leptandra, Fr.; Flüssiges Leptandraextrakt, G.

* "Leptandra, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Leptandra is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356

minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This is a fluidextract of a reddish-brown color.

Dose, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.).

Off. Prep.—Extractum Leptandræ, U. S.

FLUIDEXTRACTUM LOBELIÆ. U. S.

FLUIDEXTRACT OF LOBELIA
(lāp-īd-ēx-trăc'tūm lō-bē'lī-æ)

Extrait liquide de Lobélie enfiée, Fr.; Flüssiges Lobellenkrautextrakt, Flüssiges Lobellenextrakt, G.

* "Lobelia, in No. 50 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *two hundred and seventy-five cubic centimeters* [or 9 fluidounces, 143 minims] of Acetic Acid with *seven hundred and twenty-five cubic centimeters* [or 24 fluidounces, 247 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Acetic Acid and Water as before, until the Lobelia is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract differs from that of the U. S. P. 1890¹ in that the menstruum instead

¹ "Lobelia, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Lobelia is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890.

of being diluted alcohol, is acetic acid, diluted with 3 volumes of water; the acetic menstruum is well adapted for exhausting the drug.

This is a valuable fluidextract. It is of a dark olive color, having the acrid taste of lobelia very marked.

Dose, as an expectorant, from one to five minims (0.06 to 0.3 Ce.); as an emetic, from ten to twenty minims (0.6 to 1.3 Ce.).

FLUIDEXTRACTUM LUPULINI. U. S.

FLUIDEXTRACT OF LUPULIN [Extractum
Lupulini Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm lû-pû-lî-nî)

Extrait liqvide de Lupulin, *Fr.*; Flüssiges Lupulin-extrakt, *G.*

* "Lupulin, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Pack the Lupulin firmly in a cylindrical percolator; then add enough Alcohol to saturate the Lupulin and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Lupulin is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluidextract is of a very dark brown color, having the odor and taste of hops very distinctly. Owing to its resinous character, it is not miscible with aqueous liquids, and if desired in combination it is necessary to use gum arabic or other emulsifying agent.

Dose, from five to fifteen minims (0.3 to 0.9 Ce.).

FLUIDEXTRACTUM MATICO. U. S.

FLUIDEXTRACT OF MATICO [Extractum
Matico Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm măt'-cō)

Extrait liqvide de Matico, *Fr.*; Flüssiges Matiocobblätterextrakt, *G.*

* "Matico, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with three hundred cubic centimeters

[or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Matico is exhausted. Reserve the first eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is probably the best liquid preparation of matico; the present formula does not differ materially from that of 1870. It is a greenish-black liquid, which probably contains all of the virtues of matico, and affords an excellent form for internal administration.

Dose, from one-half to one fluidrachm (1.9 to 3.75 Ce.).

FLUIDEXTRACTUM MEZEREI. U. S.

FLUIDEXTRACT OF MEZEREUM [Extractum
Mezerei Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm mē-zē'rē-i)

Extrait liqvide de Mèzérèon (de Garou), *Fr.*; Flüssiges Seidelbastextrakt, *G.*

* "Mezereum, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of Alcohol with two hundred cubic centimeters [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Mezereum is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluidextract is identical with that formerly official. It is too acrid for internal ad-

ministration; its principal use is as the active ingredient in the stimulating ointment of mezezon which is still used.

FLUIDEXTRACTUM NUCIS VOMICÆ.

U. S. (Br.)

FLUIDEXTRACT OF NUX VOMICA [Extractum Nucis Vomicae Fluidum, Pharm. 1890]

(flû-îd-êx-tràc'tûm nû'cis vôm'î-çæ)

"A Liquid Extract containing $1\frac{1}{2}$ grains of Strychnine in 110 minims (1.5 grammes in 100 cubic centimetres)." Br.

Extractum Nucis Vomicae Liquidum, Br.; Liquid Extract of Nux Vomica; *Extrait liquide de Noix-Vomique, Fr.;* Flüssiges Krähenaugen-Extrakt, F. Brechnussextrakt, F. Strychnosamenextrakt, G.

* "Nux Vomica, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *fifty cubic centimeters* [or 1 fluid-ounce, 331 minims]; Alcohol, Water, each, *a sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol, and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Moisten the powder with *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of the mixture, to which the Acetic Acid had previously been added, and let it digest, in a well-covered vessel, in a warm place, during forty-eight hours. Then pack it in a cylindrical glass percolator, gradually pour menstruum upon it, and allow the percolation to proceed slowly until the Nux Vomica is practically exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of strychnine in the remainder of the liquid; add to this enough menstruum to make each *one hundred cubic centimeters* of the finished Fluidextract contain 1 Gm. of strychnine." U. S.

Assay. U. S. (8th Rev.)—"Fluidextract of Nux Vomica, *ten cubic centimeters*; Ammonia Water, Ether, Chloroform, Distilled Water, Normal Sulphuric Acid V.S., Sulphuric Acid Solution (3 percent. H_2SO_4), Sodium Hydroxide Solution (1 in 10), Nitric Acid (sp. gr. 1.40), Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Iodeosin T.S., each, *a sufficient quantity*. Transfer 10 Cc. of Fluidextract of Nux Vomica by means of a graduated pipette to a porcelain dish, evaporate it to dryness with the aid of a water-bath, and dissolve the residue, while

warm, in a mixture of 16 Cc. of ether, 5 Cc. of chloroform, and 4 Cc. of ammonia water, and transfer the solution to a separator, rinsing the dish with a little chloroform, which is to be added to the separator, and shake the separator carefully for a few minutes. When the fluids have separated, draw off the aqueous layer into another separator, wash the chloroform-ether liquid and separator with a little water, and add this to the second separator. Then shake the aqueous liquid with two successive portions of 15 and 10 Cc., respectively, of chloroform, and add these to the first separator. If a small portion of the liquid left in the second separator still shows, after acidifying, a reaction with mercuric potassium iodide T.S., repeat the shaking out with 10 Cc. more of chloroform. Now shake the combined liquids in the first separator with three successive portions, respectively, of 15, 10, and 10 Cc. of normal sulphuric acid V.S., and collect the combined acid solutions in another separator.

To this acid solution add a small piece of red litmus paper, and sufficient ammonia water to render it alkaline, then shake out successively with three portions, respectively, of 25, 10, and 10 Cc. of chloroform, and collect the chloroform solutions in a beaker. Evaporate the chloroform with the aid of a water-bath, dissolve the alkaloidal residue in 15 Cc. of 3 percent. sulphuric acid solution, by the aid of a water-bath, and allow the liquid to cool. To this solution add 3 Cc. of a cooled mixture of equal volumes of nitric acid (specific gravity 1.40) and distilled water, and, after rotating the liquid a few times, set it aside for exactly ten minutes, stirring it gently three times during this interval. Transfer the resulting red liquid to a separator containing 25 Cc. of an aqueous solution of sodium hydroxide (1 in 10), wash the beaker three times with very small amounts of distilled water, and add the washings to the separator. If the liquid is not quite turbid, add 2 Cc. more of the solution of sodium hydroxide. Now add 20 Cc. of chloroform to the separator, and shake it well by a rotating motion for a few minutes, allow the liquids to separate, and draw off the chloroform through a small filter, wetted with chloroform, into a flask. Repeat this twice, using 10 Cc. of chloroform each time, and draw off both portions into the flask, using the same filter. Finally, wash the filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform by means of a water-bath, very carefully, to avoid decrepitation. To the alkaloidal residue add 10 Cc. of tenth-normal sulphuric acid V.S., 5 drops of iodeosin T.S., about 80 Cc. of distilled water, and 20 Cc. of ether. When all the alkaloid is dissolved, titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., until the aqueous liquid just turns pink. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. taken, by 5, subtract this number from 10 (the 10 Cc.

of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.0332, and this product by 10, which will give the weight in grammes of strychnine contained in *one hundred cubic centimeters* of the Fluidextract of Nux Vomica." U. S.

"Moisten *one pound* (Imperial) or five hundred grammes of Nux Vomica, in No. 20 powder, with *eight fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of Alcohol (70 per cent.); set aside in a covered vessel for six hours; pack firmly in a percolator; pour over the powder sufficient of the menstruum to saturate it and to leave a stratum above it; when the liquid begins to flow, close the lower orifice; set aside for twenty-four hours; continue slow percolation, adding more menstruum as required, until *twelve fluid ounces* (Imp. meas.) or three hundred and seventy-five cubic centimetres have been collected; reserve this strong percolate. Change the receiver; continue the percolation until about *sixty fluid ounces* (Imp. meas.) or eighteen hundred and seventy-five cubic centimetres of the menstruum have been employed, or until the powder is exhausted; press the marc; add the expressed liquid to the weaker percolate; remove the alcohol by distillation; evaporate the residue to *one fluid ounce* (Imp. meas.) or thirty-one cubic centimetres; add *three fluid ounces* (Imp. meas.) or ninety-three cubic centimetres of Alcohol (90 per cent.). Add this mixture to the reserved portion; set aside for twenty-four hours; pour off the clear liquid; filter the remainder.

Determine the proportion of Strychnine in the resulting strong liquid extract by the following analytical process:

Evaporate 10 cubic centimetres to a thick syrupy consistence on a water-bath; dissolve the residue in 20 cubic centimetres of water, heating if necessary; place the solution in a separator, and add 5 grammes of sodium carbonate dissolved in 25 cubic centimetres of water, together with 10 cubic centimetres of chloroform; agitate thoroughly; set aside; separate the clear chloroformic solution. Twice repeat the agitation with chloroform, and the separation. Mix 6 cubic centimetres of diluted sulphuric acid with 25 cubic centimetres of water; divide this into three parts, and shake the mixed chloroformic solutions with each in turn. Dilute the united acid liquids with water to 175 cubic centimetres; transfer to a stoppered flask, adding 25 cubic centimetres of solution of potassium ferrocyanide; shake well and frequently during half an hour; allow to stand for 6 hours. Transfer the precipitate to a small filter, rinsing out the last portions with water containing one-fortieth of its volume of diluted sulphuric acid, and wash until the washings are free from bitterness. Rinse the precipitate into a separator. Add 5 cubic centimetres of solution of ammonia, and shake well; then add 15 cubic centimetres of chloroform in two successive portions, shaking well after

each addition; separate the chloroformic solutions, mix and allow the chloroform to evaporate in a counterpoised dish in a current of warm air; dry the residue for 1 hour on a water-bath, covering the dish to avoid loss of Strychnine from decrepitation; weigh.

From this weight calculate the amount of Strychnine in the strong liquid extract, and add to the latter sufficient Alcohol (70 per cent.) to produce a Liquid Extract of Nux Vomica containing 1.5 grammes of Strychnine in 100 cubic centimetres, or 1½ grains in 110 minims." Br.

This fluidextract has been retained principally with the view of giving the pharmacist an accurately adjusted liquid preparation of nux vomica which is more concentrated than the tincture. The process of assay is practically the same as that for the extract. The British assay process is based on that recommended by Dunstan and Short (*P. J.*, 1884, 623). The menstruum has been carefully selected so that the alkaloids shall be extracted and as much of the oil left in the residue as possible. In order to make a dry powdered extract it would be necessary to separate the fixed oil before assaying it, and then to make up the weight, if necessary, with sugar of milk or some inert, soluble powder. An important advantage, aside from that of securing uniformity and safety, is that the operator need not carry the percolation beyond the point at which it ceases to be profitable (on account of the waste of alcohol), because the extract must be brought to a definite alkaloidal strength. Such an extract can be used with great advantage to make tincture of nux vomica of definite alkaloidal strength.

Dose, from one to three minims (0.06 to 0.2 Cc.).

Off. Prep.—Tinctura Nucis Vomicae, Br.; Extractum Nucis Vomicae, Br.

FLUIDEXTRACTUM PAREIRÆ.

U. S. (Br.)

FLUIDEXTRACT OF PAREIRA [Extractum Pareiræ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm pâ-rei'ræ)

Extractum Pareiræ Liquidum, Br.; Liquid Extract of Pareira; Extrait liquide de Pareira Brava, Fr.; Flüssiges Pareiraextrakt, G.

* "Pareira, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluid-ounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in

a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water until the Pareira is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].”

U. S.

“Add to Pareira Root, in No. 40 powder, rather more than an equal bulk of boiling Distilled Water and set aside for twenty-four hours; then pack in a percolator and pass boiling Distilled Water slowly until the percolate amounts to about ten times the weight of the Pareira Root, or until the latter is exhausted. Ascertain the proportion of extractive matter in the percolate by evaporating a small weighed quantity in a counterpoised dish on a water-bath to a firm consistence, and weighing the product. Then evaporate the bulk of the percolate until the residual liquid contains one-third of its weight of such extractive matter; mix with this residual liquid sufficient Alcohol (90 per cent.) to produce from three volumes of the evaporated liquid four volumes of Liquid Extract of Pareira. Filter, or otherwise clarify, if necessary.”

Br.

The former British preparation was a concentrated solution of the extract, preserved by adding somewhat less than one-fourth of its measure of alcohol. There must be considerable loss through the action of the heat in evaporating the extract, and again through precipitation, due to attempting to dissolve an aqueous extract in a hydro-alcoholic menstruum. The present liquid extract (1898) is made by percolating the powdered root with boiling water; the process does not state how boiling distilled water is to be passed slowly, and the inference is that it is only intended that boiling water should be poured on the drug; no provision is made to prevent rapid cooling; it would probably be best to use a jacketed percolator, the space being filled with steam or hot water, if hot percolation is intended. The U. S. fluidextract is made directly from the drug, with a mixture of alcohol, water and glycerin, and is undoubtedly the better preparation.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM PHYTOLACÆ.

U. S.

FLUIDEXTRACT OF PHYTOLACCA [Extractum Phytolacæ Radicis Fluidum, Pharm. 1890]

(fîh-jd-êx-trăc'tûm phÿ-tô-lăc'cæ)

Fluidextract of Pokeroor; Extrait liquide de Phytolacque (racine), Fr.; Flüssiges Kermesbeerenwurzelextrakt, G.

* “Phytolacca, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Phytolacca is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].”

U. S.

This fluidextract was first made official in the U. S. P. 1890.

Dose, as an alterative, from one to five minims (0.06 to 0.3 Cc.), as an emetic, fifteen to thirty minims (0.9 to 1.8 Cc.).

FLUIDEXTRACTUM PILOCARPI.

U. S. (Br.)

FLUIDEXTRACT OF PILOCARPUS [Extractum Pilocarpi Fluidum, Pharm. 1890]

(fîh-jd-êx-trăc'tûm pî-lô-căr'pî)

Extractum Jaborandi Liquidum, Br.; Liquid Extract of Jaborandi; Fluidextract of Jaborandi; Extrait liquide de Jaborandi, Fr.; Flüssiges Jaborandi-extrakt, G.

* “Pilocarpus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for

forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Pilocarpus is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid by the process given below; from the results thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid; add to this enough menstruum to make each *one hundred cubic centimeters* of Fluidextract contain 0.4 Gm. of the alkaloids from Pilocarpus." U. S.

Assay. U. S. (8th Rev.)—"Fluidextract of Pilocarpus, *ten cubic centimeters*; Chloroform, Ammonia Water, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Cochineal T.S. or Iodeosin T.S., each, a *sufficient quantity*. Transfer 10 Cc. of Fluidextract of Pilocarpus by means of a graduated pipette to a porcelain dish containing a little clean sand, and evaporate it to dryness with the aid of a water-bath. Mix the sand uniformly with the extract and transfer the mixture to an Erlenmeyer flask of about 100 Cc. capacity, rinsing the dish with a mixture of 25 Cc. of chloroform and 2.5 Cc. of ammonia water. Transfer the rinsings to the flask, cork it securely, and shake it well at intervals during one hour. Decant the liquid, transfer to a separator, wash the sand with several portions of chloroform, draw off and filter the chloroformic liquid into another separator. Then shake out the chloroform solution with 15 Cc. of normal sulphuric acid V.S., transferring the acid aqueous solution to another separator. Repeat the shaking out with a mixture of 5 Cc. of normal sulphuric acid V.S. and 5 Cc. of distilled water, collecting the acid solutions in the second separator. Again repeat the shaking out with 10 Cc. of distilled water, and add the aqueous liquid to the second separator. Introduce into the second separator a small piece of red litmus paper, add enough ammonia water to render the liquid alkaline, and shake out the liquid with 20 Cc. of chloroform, drawing off the chloroformic solution into a beaker. Repeat the shaking out with two portions of 15 and 10 Cc. each of chloroform, and add the chloroformic solutions to the beaker. Evaporate the chloroform by means of a water-bath, and dissolve the alkaloidal residue in 8 Cc. of tenth-normal sulphuric acid V.S. Add 5 drops of cochineal T.S. or iodeosin T.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 8 (the 8 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.02, and this product by 10, to obtain the weight in gram-

mes of alkaloids contained in *one hundred cubic centimeters* of the Fluidextract of Pilocarpus." U. S.

"Jaborandi Leaves, in No. 20 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (45 per cent.), a *sufficient quantity*. Moisten the powdered Jaborandi Leaves with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; pack the moistened powder in a percolator, and set aside for twelve hours; then percolate with the menstruum, collecting and reserving *seventeen fluid ounces* (Imp. meas.) or eight hundred and fifty cubic centimetres of percolate; continue percolation until an additional quantity of *fifty fluid ounces* (Imp. meas.) or two and a half litres of percolate is obtained; distil the latter so as to recover the alcohol, evaporate the residual aqueous liquid to the consistence of a soft extract, adding it to the reserved percolate; to the product add sufficient of the Alcohol to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." Br.

This preparation represents jaborandi leaves thoroughly. Of the liquid preparations of the drug, the infusion and tincture are both open to objection, the former on account of the bulkiness of the dose, and the latter because of the amount of alcohol it contains.

Dose, from fifteen minims to half a fluidrachm (0.9 to 1.8 Cc.).

FLUIDEXTRACTUM PODOPHYLLI.

U. S.

FLUIDEXTRACT OF PODOPHYLLUM [Extractum Podophylli Fluidum, Pharm. 1890]

(fñ-jd-ęx-træ'túm pöd-q-phy'lli)

Fluidextract of May Apple or Mandrake; Extrait liquide de Podophylle, Fr.; Flüssiges Fussblattwurzel-extrakt, Flüssiges Podophyllumextrakt, G.

*"Podophyllum, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportion of Alcohol and Water as before, until the Podophyllum is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of

the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluid-ounces, 6½ fluidrachms].” *U. S.*

This is a fluidextract which well represents the root, but is of very little use, since podophyllum is much better administered in other forms.

Dose, from five to fifteen minims (0.3 to 0.9 Cc.).

FLUIDEXTRACTUM PRUNI VIRGINIANÆ. U. S.

FLUIDEXTRACT OF WILD CHERRY [Extractum Pruni Virginianæ Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm prû-nî vîr-jîn-î-â-næ)

Extrait liqvide d'Ecorce de Cerisier de Virginie, Fr.; Flüssiges Wildkirschenrindenextrakt, G.

* “Wild Cherry, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol and *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours; then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol to *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Water, and allow the percolation to proceed very slowly, until the Fluidextract measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This preparation has been practically more troublesome than any of the other fluidextracts. We had first Procter's original process, then his modified one, in which almonds were used to supply emulsin to assist in the development of hydrocyanic acid. (See *U. S. D.*, 15th edition, p. 637.) This was abandoned as too cumbersome in 1870, and we had the glycerin experiment. The fluidextract of 1870 deposited heavily soon after being made. The present formula is the result of much careful work on the part of the Committee, and it is

believed to be an improvement over all its predecessors.¹ J. M. Good (*Proc. A. Ph. A.*, 1897, 220) prefers repercolation, with a menstruum composed of one volume each of glycerin and alcohol and three volumes of water; each portion of drug is moistened with a mixture of one part of glycerin and two parts of water. It is of a very dark wine color, of a rough astringent taste, with a decided odor and taste of hydrocyanic acid.

Dose, from thirty minims to a fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM QUASSIÆ. U. S.

FLUIDEXTRACT OF QUASSIA [Extractum Quassiæ Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm quâs-sî-æ)

Extrait liqvide de Quassie, Fr.; Flüssiges Quassiaextrakt, G.

* “Quassia, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Quassia is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This fluidextract is an active preparation. The British “Liquor Quassiæ Concentratus” is

¹ *Fluidextract of Wild Cherry* (Improved).—This process is advocated by Cyrus M. Boger, who states that all of the hydrocyanic acid is developed, tannin is excluded as much as possible, and consequently precipitation is reduced to the lowest point. “Take of Ground Wild Cherry Bark, *ten troyounces*; Water and Alcohol, each, *ten fluidounces*; Glycerin, *four fluidrachms*. Moisten the bark with *ten fluidounces* of water and put loosely in the percolator, close tightly, and allow it to macerate sixty hours; then pack very firmly, mix the *ten fluidounces* of alcohol and *four* of glycerin and pour it upon the bark; now cork up the percolator tightly and macerate twenty-four hours longer; at the expiration of this time remove the cork, and about *twelve fluidounces* of percolate will come through; water should now be poured on to force the other *four fluidounces* out, when the percolation should be stopped and the product will be finished.” (*A. J. P.*, 1887, pp. 231, 232.)

made with alcohol (20 per cent.) as a menstruum and has one-tenth the strength of the U. S. fluidextract.

Dose, from five to ten minims (0.3 to 0.6 Cc.).

FLUIDEXTRACTUM QUERCUS. U. S.

FLUIDEXTRACT OF QUERCUS

(flû-îd-êx-trăc'tûm quěr'cûs)

Fluidextract of White Oak Bark; Extrait liquide d'Ecorce de Chêne, *Fr.*; Flüssiges Elchenrindenextrakt, *G.*

* "Quercus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Diluted Alcohol, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Quercus is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract was admitted to the U. S. P. (8th Rev.) for the first time. It represents the virtues of oak bark.

Dose, fifteen minims to one fluidrachm (0.9 to 3.75 Cc.).

FLUIDEXTRACTUM QUILLAJÆ. U. S.

FLUIDEXTRACT OF QUILLAJA

(flû-îd-êx-trăc'tûm quil-lă'jæ)

Fluidextract of Soap Bark; Extrait liquide d'Ecorce de Quillaja, *Fr.*; Flüssiges Seifenrindenextrakt, *G.*

* "Quillaja, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it.

When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Quillaja is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract was admitted to the U. S. P. (8th Rev.) for the first time. It represents the soluble principles from quillaja.

Dose, three to ten minims (0.2 Cc. to 0.6 Cc.).

FLUIDEXTRACTUM RHAMNI PURSHIANÆ. U. S. (Br.)

FLUIDEXTRACT OF CASCARA SAGRADA

[Extractum Rhamni Purshianæ Fluidum, *Pharm.* 1890]

(flû-îd-êx-trăc'tûm rhâm'ni pûr-shi-ă'næ)

Extractum Cascaræ Sagradæ Liquidum, *Br.*; Liquid Extract of Cascara Sagrada; Extrait liquide de Cascara Sagrada, *Fr.*; Flüssiges Cascara-Sagrada-extrakt, *G.*

* "Cascara Sagrada, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, until the Cascara Sagrada is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

"Cascara Sagrada, in No. 20 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (90 per cent.), 4 fl. ounces (Imp. meas.) or 200 cubic centimetres; Distilled Water, *a sufficient quantity*. Moisten the Cascara Sagrada with *fifteen fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres of the Distilled Water, and set the mixture aside for six hours;

then place it loosely in a percolator and percolate with more of the Distilled Water until the powder is exhausted; evaporate the percolate to *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres; add the Alcohol, previously mixed with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of Distilled Water or with sufficient to make up the volume of the mixed liquids to *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.* This process has been improved by the adoption of percolation in the *Br. Ph.* 1898 in place of evaporating decoctions, and preserving the residue with alcohol.

This fluidextract is a good preparation, but the aromatic fluidextract is more largely used.

Dose, fifteen minims to one fluidrachm (0.9 to 3.75 Cc.).

Off. Prep.—Syrupus Cascaræ Aromaticus, *Br.*

FLUIDEXTRACTUM RHAMNI PURSHIANÆ AROMATICUM. U. S.

AROMATIC FLUIDEXTRACT OF CASCARA SAGRADA

(flâ-jd-êx-trăc'tûm rhâm'ni pûr-shî-ân-æ
âr-q-mât'î-cûm).

Tasteless Fluidextract of Cascara Sagrada; *Ex-*
trait liquide Aromatique de Cascara Sagrada, *Fr.*;
Bitterloses flüssiges Cascara-Sagradaextract, *G.*

* "Cascara Sagrada, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycyrrhiza, in No. 30 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Magnesium Oxide, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Glycerin, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Compound Spirit of Orange, *ten cubic centimeters* [or 162 minims]; Alcohol, Diluted Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Cascara Sagrada, Glycyrrhiza, and Magnesium Oxide thoroughly, and, having added *two thousand cubic centimeters* [or 67 fluidounces, 301 minims] of Water, allow the mixture to macerate for twelve hours, and then dry it at a gentle heat. Mix the Glycerin with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the re-

mainder of the menstruum, and afterwards Diluted Alcohol, until the powder is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, add the Compound Spirit of Orange and enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters*¹ [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This aromatic fluidextract was introduced into the *U. S. P.* (8th Rev.) for the first time. It is given as a laxative, the object of the addition of magnesium oxide is to destroy the bitter taste of the cascara sagrada. Lime is sometimes used instead of magnesia but it has been shown that lime acts injuriously upon the laxative principles of cascara sagrada. The fluidextract is very largely used.

Dose, fifteen minims to one fluidrachm (0.9 to 3.75 Cc.).

FLUIDEXTRACTUM RHEI. U. S.

FLUIDEXTRACT OF RHUBARB [Extractum
Rhei Fluidum, Pharm. 1890]

(flâ-jd-êx-trăc'tûm rhê'î)

Extrait liquide de Rhubarbe, *Fr.*; Flüssiges Rhubarberextrakt, *G.*

* "Rhubarb, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Rhubarb is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder, at a temperature not

¹ *Aromatic Fluidextract of Cascara Sagrada* (bitterless).—L. C. Urban prefers lime to magnesia, as suggested by H. B. Gilpin, for making a palatable preparation of cascara. His process is as follows: 1000 Gm. ground cascara sagrada, 150 Gm. ground licorice root, and 100 Gm. freshly slaked lime are kneaded with 1000 Cc. of water, allowed to stand twelve hours, and then dried at 50° C. The dried drugs are moistened with 400 Cc. of a menstruum made by mixing 500 Cc. alcohol and 250 Cc. glycerin with 250 Cc. water, and percolated with sufficient of the menstruum, followed by water, to exhaust the drug. The first 850 Cc. are reserved, then mixed with the balance of the percolate, evaporated to a soft extract, and 12 Cc. of compound spirit of orange added. (*Ph. Rev.*, 1896, 270.)

exceeding 70° C. (158° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

Although the process for the fluidextract of rhubarb of *U. S. P.* 1870 was an improvement on its predecessors, on the addition of water the fluidextract precipitated heavily, so that syrups or mixtures made with it were very unsightly. As the chief use of the fluidextract is in making such preparations, this was very unfortunate, and constituted sufficient grounds for the abandonment of this formula in favor of one which will exhaust the root of its purgative properties and yet yield a preparation that will remain clear when water is added to it. Geo. Bille claims that all that is necessary is to exhaust the sixteen troyounces of rhubarb with cold water, evaporate, by means of a water-bath, to twelve fluidounces, and add four fluidounces of glycerin. The present process affords a fluidextract which thoroughly represents the root, but it has in a degree the same objection that the former preparation had, immiscibility with syrups and water, with loss of transparency. An alkali or an alkaline carbonate dissolves this precipitate, but the use of the fluidextract is limited. The British “*Liquor Rhei Concentratus*” is made with alcohol (20 per cent.) as a menstruum and is one-half the strength of the *U. S.* fluidextract of rhubarb.

Dose, for an adult, as a purgative, twenty to thirty minims (1.3 to 1.8 Cc.); as a laxative, from five to ten minims (0.3 to 0.6 Cc.).

FLUIDEXTRACTUM RHOIS GLABRÆ. *U. S.*

FLUIDEXTRACT OF RHUS GLABRA [Extractum
Rhois Glabræ Fluidum, Pharm. 1890]

(flû-jd-èx-trăc'tûm rhô'is glă'bræ)

Fluidextract of Sumach Berries; *Extrait liquide de fruit de Sumac, Fr.*; Flüssiges Sumachbeeren-extrakt, *G.*

* “*Rhus Glabra*, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Diluted Alcohol, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for

forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the *Rhus Glabra* is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

A formula for this preparation was proposed by J. P. Remington (*A. J. P.*, 1874, p. 7) which differs from that at present official merely in containing a somewhat larger proportion of glycerin in the menstruum. Experience has shown that this is a valuable preparation of sumach berries, and is a useful addition to mouth and throat washes, gargles, etc.

Dose, ten to twenty minims (0.6 to 1.3 Cc.).

FLUIDEXTRACTUM ROSÆ. *U. S.*

FLUIDEXTRACT OF ROSE [Extractum
Rosæ Fluidum, Pharm. 1890]

(flû-jd-èx-trăc'tûm rō'sæ)

Fluidextract of Red Rose; *Extrait liquide de Rose rouge, Fr.*; Flüssiges Essigrosenblumenblättere-extrakt, *G.*

* “*Red Rose*, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Diluted Alcohol, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the *Red Rose* is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder, in a porcelain dish, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This fluidextract is a useful adjuvant and an elegant astringent. It is of a deep red color, with the agreeable flavor of rose. *Wm.*

C. Alpers prefers repercolation for this fluid-extract, stating that even a moderate heat imparts an unpleasant odor to the finished product. (*Proc. A. Ph. A.*, 1897, 425.)

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

Off. Prep.—Mel Rosæ, *U. S.*; Syrupus Rosæ, *U. S.*

FLUIDEXTRACTUM RUBI. U. S.

FLUIDEXTRACT OF RUBUS [Extractum
Rubi Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm rū'bi)

Fluidextract of Blackberry Bark; Extrait liuide d'Ecorce de Ronce, *Fr.*; Flüssiges Brombeerrinden-extrakt, *G.*

* "Rubus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluid-ounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Rubus is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid-extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluidextract does not differ essentially from that formerly official. It is a very dark reddish-brown, translucent fluid, having the properties of the root in a marked degree.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

Off. Prep.—Syrupus Rubi, *U. S.*

FLUIDEXTRACTUM SABINÆ. U. S.

FLUIDEXTRACT OF SAVIN [Extractum
Sabinæ Fluidum, Pharm. 1890]

(flû-jd-êx-trăc'tûm sâ-bī'nê)

Extrait liuide de Sabine, *Fr.*; Flüssiges Sadebaumsitzenextrakt, *G.*

* "Savin, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred and fifty cubic centimeters* [or 8 fluid-

ounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Savin is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is identical with the fluidextract formerly official. It is a dark greenish-black fluid, not mixing well with aqueous liquids without the use of an emulsifying agent. It is rarely given internally.

Dose, from three to eight minims (0.2 to 0.5 Cc.).

FLUIDEXTRACTUM SANGUINARIÆ. U. S.

FLUIDEXTRACT OF SANGUINARIA

(flû-jd-êx-trăc'tûm sân-gui-nâ'ri-æ)

Fluid Extract of Bloodroot; Extrait liuide de Sanguinaire, *Fr.*; Flüssiges Blutwurzelextrakt, *G.*

* "Sanguinaria, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *two hundred and seventy-five cubic centimeters* [or 9 fluidounces, 143 minims] of Acetic Acid with *seven hundred and twenty-five cubic centimeters* [or 24 fluidounces, 247 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, allow it to macerate, in a well-covered vessel, during forty-eight hours. Then pack it firmly in a cylindrical glass percolator, gradually pour menstruum upon it, using the same proportions of Acetic Acid and Water as before, and allow the percolation to proceed slowly, until the Sanguinaria is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The liquid preparations of sanguinaria all have an unfortunate tendency to precipitate, and this fluidextract will not prove an exception, although the acetic acid used as a menstruum will have a tendency to prevent pre-

ecipitation. It is of a very deep red color. The process for the U. S. P. 1890 fluidextract is appended.¹

Dose, from one to five minims (0.06 to 0.3 Cc.).

FLUIDEXTRACTUM SARSAPARILLÆ.

U. S. (Br.)

FLUIDEXTRACT OF SARSAPARILLA [Extractum Sarsaparillæ Fluidum, Pharm. 1890]

(flû-îd-êx-trâc'tûm sâr-sa-pa-ril'læ)

Extractum Sarsæ Liquidum, Br.; Liquid Extract of Sarsaparilla; *Liquor Sarsæ*; *Extrait Liquide de Salsepareille, Fr.*; Flüssiges Sarsaparillaextract, G.

* "Sarsaparilla, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Sarsaparilla is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

"Sarsaparilla, in No. 40 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (20 per cent.), *a sufficient quantity*; Glycerin, 2 fl. ounces (Imp. meas.) or 100 cubic centimetres. Divide the Sarsaparilla into three

portions. Moisten one portion with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol; pack in a percolator; set aside for twenty-four hours; percolate with the Alcohol until a quantity of *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres is obtained. Moisten the second portion of the drug with this liquid; pack in a percolator; set aside for twenty-four hours; percolate with a menstruum obtained by further percolation of the first portion; continue until a quantity of *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres is obtained. Moisten the third portion of the drug with this liquid; pack in a percolator; set aside for twenty-four hours; percolate with a menstruum obtained by successive percolation through the first and second portions as directed above; collect *eighteen fluid ounces* (Imp. meas.) or nine hundred cubic centimetres from the third percolator; add the Glycerin. The product should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." Br.

The British Pharm. (1898) has greatly improved the process for this preparation, having abandoned maceration for repercolation; glycerin is used as a preservative, being added to the reserved portion; the reason for not using the glycerin in the first percolate to aid in the extraction is not apparent. The introduction of a simple fluidextract of sarsaparilla into our Pharmacopœias was judicious, as it enables the physician to associate this medicine with others at his pleasure, and in such proportions as he may deem expedient. He may rely upon the efficiency of the preparation, if made with sufficient care and skill and from good parcels of the root. The U. S. fluidextract is a somewhat dense, scarcely translucent liquid, of a very dark reddish-brown color, and of a sweetish and a slightly acid taste.

Dose, of U. S. fluidextract, from thirty to sixty minims (1.8 to 3.75 Cc.); as given in the British Pharmacopœia, from two to four fluidrachms (7.5 to 15 Cc.).

* "Sarsaparilla, in No. 30 powder, *seven hundred and fifty grammes* [or 26 ounces av., 199 grains]; Glycyrrhiza, in No. 30 powder, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Sassafras, in No. 30 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Mezereum, in No. 30 powder,

¹ "Sanguinaria, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, to which the Acetic Acid had previously been added, and let it macerate, in a well-covered vessel, in a warm place, during forty-eight hours. Then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until the Sanguinaria is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890.

thirty grammes [or 1 ounce av., 25 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Diluted Alcohol, and, having moistened the mixed powders with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then Diluted Alcohol, until the powder is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

Everything depends in the process upon having the several ingredients, equally powdered, mixing them well and duly moistening them, and then packing them properly in the percolator. The moistening of the mixed powders is more easily effected, as they are less disposed to form lumps than is the sarsaparilla powder alone. The preparation is intended to represent, in a concentrated state, the compound decoction of sarsaparilla, having all its ingredients with the exception of the guaiacum wood, which probably adds little to the efficacy of the decoction. It was originally proposed by Wm. Hodgson, Jr. (*A. J. P.*, ii. 285), and the official process differs from his mainly in the omission of the guaiacum wood, the resin of which, separating during the evaporation, somewhat embarrassed the process, without adding to the virtues of the extract. The British "*Liquor Sarsæ Compositus Concentratus*" is of the same strength as the fluidextract of the U. S. Pharmacopœia, and is made with a menstruum of distilled water with 225 Cc. of alcohol as a preservative in 1000 Cc. of finished solution.

Dose, from thirty minims to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM SCILLÆ. U. S.

FLUIDEXTRACT OF SQUILL

(flû-îd-êx-trăc'tûm scîl'læ)

Extrait liquide de Scille, *Fr.*; Flüssiges Meer-swiebelextrakt, *G.*

* "Squill, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, Water, each, *a sufficient quantity*, to

make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *two hundred and seventy-five cubic centimeters* [or 9 fluidounces, 143 minims] of Acetic Acid with *seven hundred and twenty-five cubic centimeters* [or 24 fluidounces, 247 minims] of Water, and, having added *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the mixture to the powder, allow it to macerate, in a well-covered glass or porcelain vessel, during forty-eight hours, then transfer it to a conical glass percolator, and allow the percolation to proceed slowly, adding menstruum gradually, using the same proportions of Acetic Acid and Water as before, until the Fluidextract measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S. The process of the U. S. P. 1890 is appended.¹

This fluidextract is made with a diluted acetic acid menstruum (1 to 3). The only objection to the menstruum is that it makes a very thick fluidextract and the percolation is slow, but the solvent powers of the acetic acid are remarkable. J. U. Lloyd recommended diluted acetic acid for a menstruum, and that this fluidextract should be made half strength,—*i. e.*, 2 Cc. represent 1 Gm. (See *Am. Drug.*, 1886, p. 202.)

Dose, from two to three minims (0.12 to 0.2 Cc.).

Off. Prep.—Syrupus Scillæ Compositus, U. S.

FLUIDEXTRACTUM SCOPOLÆ. U. S.

FLUIDEXTRACT OF SCOPOLA

(flû-îd-êx-trăc'tûm scô-pô'læ)

Extrait liquide de Racine de Scopola, *Fr.*; Flüssiges Skopolawurzelextrakt, *G.*

* "Scopola, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with

¹ "Squill, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the mixture, pack it in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Squill is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890.

three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Scopola is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay ten cubic centimeters of this liquid as directed below; from the result thus obtained, ascertain by calculation the amount of mydriatic alkaloids in the remainder of the liquid, and add to this enough menstruum to make each one hundred cubic centimeters of the finished Fluidextract contain 0.5 Gm. of the mydriatic alkaloids from Scopola." U. S.

Assay. U. S. (8th Rev.).—"The method to be employed is identical with that given for Fluidextract of Belladonna Root, using ten cubic centimeters of Fluidextract of Scopola." U. S.

This fluidextract was made official for the first time in the U. S. P. (8th Rev.). It may be used for the same purposes as fluidextract of belladonna root.

Dose, from one to three minims (0.06 to 0.2 Cc.).

Off. Prep.—Extractum Scopolæ, U. S.

FLUIDEXTRACTUM SCUTELLARIÆ.

U. S.

FLUIDEXTRACT OF SCUTELLARIA [Extractum
Scutellariæ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm scû-têl-lă-rî-æ)

Fluidextract of Skullcap; Extrait Liquide de Scutellaire, Fr.; Flüssiges Helmkrautextract, G.

* "Scutellaria, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Scutellaria is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate,

and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract thoroughly represents the activity of scutellaria. It is of a dark greenish-brown color.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM SENEGÆ. U. S.

FLUIDEXTRACT OF SENEGA [Extractum
Senegæ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm sên-ê-gæ)

Extrait Liquide de Polygale de Virginie, Extrait Liquide de Sénéca, Fr.; Flüssiges Senegaextract, G.

* "Senega, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Solution of Potassium Hydroxide, thirty cubic centimeters [or 1 fluidounce, 7 minims], Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Solution of Potassium Hydroxide with six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol and three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol to three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water, until the Senega is exhausted. Reserve the first eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, in a porcelain dish, to a soft extract; dissolve this in the reserved portion, and add enough of the last-mentioned mixture of Alcohol and Water to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S.

Formerly, Fluidextract of Senega was very frequently the cause of annoyance to the pharmacist through gelatinization. This was due to the presence of pectinous bodies in the root. The addition of a fixed alkali to the menstruum effectually prevents this, and in this respect the present preparation is a great improvement over the 1890 fluidextract. It is a blackish-brown, moderately thin liquid. For other processes, see N. R., 1883, pp. 195, 196. The British

"Liquor Senegæ Concentratus" is made half the strength of the U. S. fluidextract with a menstruum composed of 2 parts of 20 per cent. alcohol and 1 part of 45 per cent. alcohol.

Dose, from five to twenty minims (0.3 to 1.3 Cc.).

Off. Prep.—Syrupus Scillæ Compositus, U. S.; Syrupus Senegæ, U. S.

FLUIDEXTRACTUM SENNÆ. U. S.

FLUIDEXTRACT OF SENNA [Extractum
Sennæ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm sên'næ)

Extrait liquide de Séné, Fr.; Flüssiges Sennaextrakt, G.

* "Senna, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Diluted Alcohol, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Alcohol, pack it firmly in a cylindrical percolator, and percolate it with Alcohol until the Senna is exhausted. The alcoholic percolate thus obtained is to be rejected. Remove the powder from the percolator, dry it, and, having moistened it with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Senna is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

The official fluidextract of senna of 1870 differed materially from that of the Pharmacopœias of 1850 and 1860, containing neither sugar, oil of fennel, nor Hoffmann's anodyne. It was deemed better to leave to the prescriber the choice of the volatile oil, and to depend for the preservation of the fluidextract upon the glycerin and what might remain of the alcohol after the evaporation. The U. S. P. 1890 fluidextract, which was practically identical with of the U. S. P. 1880, is very different from that of 1870, which contained 50 per cent. of glycerin. There was no glycerin in the menstruum of 1890, and there really seems to be no occasion for its use. The U. S. P. (8th Rev.) process provides for the elimination of the griping principles by the previous percolation

of the powdered senna with alcohol; diluted alcohol is then used to exhaust the drug of the purgative principles. The fluidextract is a dark, blackish, thick, and somewhat turbid liquid, with a strong flavor of senna. It is well adapted for exhibition with saline cathartics, such as Epsom salt or cream of tartar, which also obviate its griping. In this case not more than one-half of the full dose of the fluidextract should be given at once.

The British "Liquor Sennæ Concentratus" is more like a concentrated infusion than a fluidextract, but has the same strength of the latter, the menstruum is distilled water; tincture of ginger and alcohol being added.

Dose, from one-half to two fluidrachms (1.8 to 7.5 Cc.) for an adult.

Off. Prep.—Syrupus Sarsaparillæ Compositus, U. S.; Syrupus Sennæ, U. S.

FLUIDEXTRACTUM SERPENTARIÆ. U. S.

FLUIDEXTRACT OF SERPENTARIA [Extractum
Serpentariæ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm sêr-pen-tă'rî-æ)

Fluidextract of Virginia Snake Root; Extrait liquide de Serpentinaire, Fr.; Flüssiges Schlangengurzelextrakt, G.

* "Serpentaria, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Serpentinaire is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This, though simply a concentrated tincture, is a good preparation, containing the virtues of the root within a small bulk. The fluidextract of serpentaria originated with J. C. Savery, whose formula was published in the eleventh edition of the U. S. Dispensatory (page 713). It was afterwards modified by A. B. Taylor (A.

J. P., xxv. 206). In the present preparation the alcoholic strength of menstruum is slightly less than that of the fluidextract of U. S. P. 1870. The fluidextract is thin, reddish brown, and transparent, having the peculiar bitterness and odor of the root in perfection. The British "Liquor Serpentariæ Concentratus," is half the strength of the U. S. fluidextract, the menstruum being alcohol (20 per cent.).

Dose, twenty to thirty minims (1.3 to 1.8 Ce.).

FLUIDEXTRACTUM SPIGELIÆ. U. S.

FLUIDEXTRACT OF SPIGELIA [Extractum
Spigeliæ Fluidum, Pharm. 1890]

(flû-jd-êx-trâc'tûm spi-gê'lî-æ)

Fluidextract of Pink Root; *Extrait liquide de Spigelle, Fr.*; *Flüssiges Spigelenextrakt, G.*

* "Spigelia, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Spigelia is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This preparation differs from that official prior to 1890 in having no glycerin in the menstruum; the U. S. P. 1870 fluidextract had 50 per cent.

The fluidextract of spigelia is a dark-brown translucent liquid, with the flavor of the root. The dose may be repeated morning and evening for three or four days, and then followed by a brisk cathartic. It is, however, most used in connection with the fluidextract of senna, the fluidextract of spigelia and senna formerly official being an excellent combination, which should not have been dropped from the Pharmacopœia.¹

¹ *Extractum Spigeliæ et Sennæ Fluidum, U. S. 1870. Fluid Extract of Spigelia and Senna.*—"Take of Fluid Extract of Spigelia *ten fluidounces*; Fluid Extract of Senna, *six fluidounces*; Oil of Anise, Oil of Caraway, each, *twenty minims*. Mix the Fluid Extracts, and dissolve the Oils in the mixture." U. S. 1870.

It combines the cathartic property of senna with the anthelmintic virtues of pinkroot, and is a very good vermifuge, being generally acceptable to the stomach, and not offensive to the taste. The dose is from two fluidrachms to half a fluidounce (7.5 to 15 Ce.) for an adult, from thirty minims to a fluidrachm (1.8 to 3.75 Ce.) for a child two years old.

Dose, for an adult, from one to two fluidrachms (3.75 to 7.5 Ce.); for a child of two or three years, from ten to twenty minims (0.6 to 1.3 Ce.).

FLUIDEXTRACTUM STAPHISAGRIÆ.

U. S.

FLUIDEXTRACT OF STAPHISAGRIA

(flû-jd-êx-trâc'tûm stâph-i-sâ'grî-æ)

Fluidextract of Stavesacre Seed; *Extrait liquide des Semences de Staphisaigre, Fr.*; *Flüssiges Staphanskörnerextrakt, G.*

* "Staphisagria, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Staphisagria is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluidextract was first made official in the U. S. P. (8th Rev.). Mixed with alcohol and ether, it is used as an external application to destroy lice.

FLUIDEXTRACTUM STILLINGIÆ.

U. S.

FLUIDEXTRACT OF STILLINGIA [Extractum
Stillingiæ Fluidum, Pharm. 1890]

(flû-jd-êx-trâc'tûm stjîl-îng'i-æ)

Extrait liquide de Stillingie, Fr.; *Flüssiges Stillingiaextrakt, G.*

* "Stillingia, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid

begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the *Stillingia* is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

The glycerin in the menstruum has been abandoned in this fluidextract, which is of a dark reddish-brown color.

Dose, from fifteen to forty-five minims (0.9 to 2.8 Ce.).

FLUIDEXTRACTUM STRAMONII.

U. S.

FLUIDEXTRACT OF STRAMONIUM

(fû-îd-êx-trăc'tûm stră-mo'ni-i)

Extrait liquide de Feuilles de Stramoine, *Fr.*;
Flüssiges Stechapfelblätterextrakt, *G.*

* “*Stramonium*, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the *Stramonium* is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay *ten cubic centimeters* of this liquid, as directed below; from the results thus obtained, ascertain by calculation the amount of mydriatic alkaloids in the remainder of the liquid, and add to this enough menstruum to make each *one hundred cubic centimeters* of the finished Fluidextract contain 0.35 Gm. of the mydriatic alkaloids from *Stramonium*.” *U. S.*

Assay. *U. S.* (8th Rev.)—“The method to be employed is identical with that given for Fluidextract of *Belladonna Root*, using *ten cubic centimeters* of Fluidextract of *Stramonium*.” *U. S.*

This is a fluidextract the menstruum of which is well adapted for thoroughly exhausting the drug. *Stramonium* leaves are now used instead of *stramonium seed*, for making the fluidextract, which is of a dark brown color.

Dose, from one to two minims (0.06 to 0.12 Ce.).

Off. Prep.—Extractum *Stramonii*, *U. S.*

FLUIDEXTRACTUM SUMBUL. U. S.

FLUIDEXTRACT OF SUMBUL

(fû-îd-êx-trăc'tûm sũm'bũl)

Fluidextract of Muskroot; Extrait liquide de Sumbul, *Fr.*; Flüssiges Sumbulwurzelextrakt oder Moschuswurzelextrakt, *G.*

* “*Sumbul*, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the *Sumbul* is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This fluidextract was made official for the first time in the *U. S. P.* (8th Rev.), superseding the tincture of *sumbul*, to which it is superior.

Dose, half a fluidrachm to one fluidrachm (1.8 to 3.75 Ce.).

Off. Prep.—Extractum *Sumbul*, *U. S.*

FLUIDEXTRACTUM TARAXACI.

U. S. (Br.)

FLUIDEXTRACT OF TARAXACUM [Extractum Taraxaci Fluidum, Pharm. 1890]

(fû-îd-êx-trăc'tûm tă-răx'a-ci)

Extractum *Taraxaci Liquidum*, *Br.*; Liquid Extract of *Taraxacum*; Fluidextract of *Dandelion*; Extrait liquide de Pissenlit, *Fr.*; Flüssiges Löwenzahnwurzelextrakt, *G.*

* “*Taraxacum*, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Solution of *Sodium Hydroxide*, *fifty cubic*

centimeters [or 1 fluidounce, 331 minims]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol, until the Taraxacum is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, add the Solution of Sodium Hydroxide, and enough Diluted Alcohol to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms].” U. S.

“Taraxacum Root, dried, in No. 20 powder, 20 ounces (Imperial) or 1000 grammes; Alcohol (60 per cent.), 2 pints (Imp. meas.) or 2000 cubic centimetres; Distilled Water, a sufficient quantity. Mix the powdered Taraxacum Root with the Alcohol; set aside in a closed vessel for forty-eight hours; press out ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of liquid; set the latter aside; mix the pressed residue with two pints (Imp. meas.) or two thousand cubic centimetres of the Distilled Water; set aside for forty-eight hours; press out and strain the liquid; evaporate to about ten [fluid] ounces (Imp. meas.) or five hundred cubic centimetres; mix the two liquids; if necessary make up the volume to twenty fluid ounces (Imp. meas.) or one thousand cubic centimetres by the addition of Distilled Water; filter.” Br. It is to be regretted that the Br. Pharm. (1898) did not adopt percolation for this preparation, as it can be practiced here with great success.

The activity depends more upon the proper selection of the root than upon anything else. The addition of a small quantity of solution of sodium hydroxide increases the efficiency of the fluidextract. The process of exhausting the drug is not difficult, and one of the best tests of this fluidextract is its bitter taste. It is a blackish, moderately thick liquid.

Dose, from one to three fluidrachms (3.75 to 11.25 Ce.).

FLUIDEXTRACTUM TRITICI. U. S.

FLUIDEXTRACT OF TRITICUM [Extractum
Tritici Fluidum, Pharm. 1890]

(flâ-îd-êx-trâc'tûm trit'î-ci)

Fluidextract of Couch-grass Root; Extrait liquide de petit Chlorient, Fr.; Flüssiges Queckenwurzels-extrakt, G.

* “Triticum, finely cut, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol,

Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Pack the Triticum in a cylindrical metallic percolator, pour boiling Water upon it, and allow the percolation to proceed, supplying boiling Water, as required, until the Triticum is exhausted. Evaporate the percolate to seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims], and, having added to it two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Alcohol, mix well and set it aside for forty-eight hours. Then filter the liquid and add to the filtrate enough of a mixture of Alcohol and Water made in the proportion of one volume of Alcohol to three volumes of Water to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms].” U. S.

In making this fluidextract in warm weather, it is advisable to commence evaporating the percolate before the drug is exhausted, or fermentation may set in; triticum contains fermentable sugars, and diluted aqueous solutions do not keep well.

This fluidextract is a valuable preparation. The German Pharmacopœia directed an *Extractum Graminis*, by digesting 1 part of Triticum with 6 parts of hot water, for six hours, straining, evaporating to a syrup, mixing 1 part of this extract with 4 parts of cold distilled water, filtering, and evaporating to an extract. The fluidextract is preferable, as the excessive use of heat is avoided.

Dose, from three to six fluidrachms (11.25 to 22.5 Ce.).

FLUIDEXTRACTUM UVÆ URSI. U. S.

FLUIDEXTRACT OF UVA URSI [Extractum
Uvæ Ursi Fluidum, Pharm. 1890]

(flâ-îd-êx-trâc'tûm úv'æ úr'si)

Extrait liquide de Busserole, Fr.; Flüssiges Bärentraubenblätterextrakt, G.

* “Uva Ursi, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, three hundred cubic centimeters [or 10 fluidounces, 69 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with two hundred cubic centimeters [or 6 fluidounces, 366 minims] of Alcohol and five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Water, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding, first, the remainder

of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol to *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, until the Uva Ursi is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough of the mixture of Alcohol and Water to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This preparation is a dense, black liquid, of a sweet, bitterish, astringent, but not very disagreeable taste.

Dose, from thirty minims to a fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM VALERIANÆ. U. S.

FLUIDEXTRACT OF VALERIAN [Extractum
Valerianæ Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm vâ-lê-rî-ă-næ)

Extrait Liquide de Valériane, *Fr.*; Flüssiges Baldrianextrakt, *G.*

* “Valerian, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator, then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Valerian is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This is a concentrated tincture, strong both in alcohol and in the virtues of valerian. It is probable that all or nearly all the volatile ingredients of the root are extracted by the reserved portion which first passes, and which,

not being exposed to evaporation, loses none of the volatile oil and acid that have been dissolved, while the soluble matter subsequently extracted, consisting chiefly of the fixed principles, will not be dissipated by the concentration ordered. The fluidextract may therefore be considered as fully representing the virtues of the root. The formula is, with some modification, that of Grahame (*A. J. P.*, xxi. 379). The preparation is a dark brownish-red liquid, transparent in thin layers, with the odor and taste of valerian.

Dose, thirty minims to a fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM VERATRI. U. S.

FLUIDEXTRACT OF VERATRUM [Extractum
Veratri Viridis Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm vê-ră'trî)

Fluidextract of American Hellebore; Extrait Liquide de Veratre américain, *Fr.*; Flüssiges Grüngermerextrakt, *G.*

* “Veratrum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Veratrum is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This is the best preparation of veratrum and thoroughly represents the drug.

Dose, one to two minims (0.06 to 0.12 Cc.).

FLUIDEXTRACTUM VIBURNI OPULI. U. S.

FLUIDEXTRACT OF VIBURNUM OPULUS
[Extractum Viburni Opuli Fluidum, Pharm. 1890]

(flû-îd-êx-trăc'tûm vî-bûr'nî ôp'û-li)

Fluidextract of Cramp Bark; Flüssiges Schneeballrindenextrakt, *G.*

* “Viburnum Opulus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].

Mix six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the *Viburnum Opulus* is exhausted. Reserve the first eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluidextract was first introduced into the *U. S. P.* 1890: there seems to be little necessity for two fluidextracts of viburnum.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM VIBURNI PRUNIFOLII. *U. S.*

FLUIDEXTRACT OF VIBURNUM PRUNIFOLIUM
[Extractum Viburni Prunifolii Fluidum, Pharm. 1890]

(fū-jd-ḡ-trăc'tūm vī-bŭr'nī prŭ-nj-fō'lī-i)

Fluidextract of Black Haw; *Extrait Liquide de Viburne, Fr.*; Flüssiges Viburnumextract, *G.*

* "*Viburnum Prunifolium*, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the *Viburnum Prunifolium* is exhausted. Reserve the first eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add

enough menstruum to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluidextract which well represents the drug. It is of a dark reddish-brown color.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM XANTHOXYLI. *U. S.*

FLUIDEXTRACT OF XANTHOXYLUM [Extractum Xanthoxyli Fluidum, Pharm. 1890]

(fū-jd-ḡ-trăc'tūm xan-thōx'y-lī)

Fluidextract of Prickly Ash; *Extrait Liquide d'Ecorce de Clavaller, Fr.*; Flüssiges Zahnwehrinden-extrakt, *G.*

* "*Xanthoxylum*, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the *Xanthoxylum* is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluidextract thoroughly represents the virtues of the drug.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

FLUIDEXTRACTUM ZINGIBERIS. *U. S.*

FLUIDEXTRACT OF GINGER [Extractum Zingiberis Fluidum, Pharm. 1890]

(fū-jd-ḡ-trăc'tūm zjŋ-gīb'ē-rīs)

Extrait Liquide de Gingembre, Fr.; Flüssiges Ingwerextrakt, *G.*

* "*Ginger*, in No. 50 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with two hundred and fifty cubic centimeters [or 8 fluid-

ounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Ginger is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” U. S.

This fluidextract is a highly concentrated alcoholic solution of the active principles of ginger. It is transparent, and of a reddish color.

Dose, from ten to twenty minims (0.6 to 1.3 Cc.).

Off. Prep.—Syrupus Zingiberis, U. S.

FENICULUM. U. S. (Br.)

FENNEL

(fœ-nîc'û-lûm)

“The dried, nearly ripe fruit of *Feniculum vulgare* Miller (Fam. Umbelliferae).” U. S.
 “The dried ripe fruit of *Feniculum capillaceum*, Gilib., collected from cultivated plants.” Br.

Feniculi Fructus, Br.; Semen Fœniculi, Fennel Fruit (Seed), Sweet Fennel Fruit; Fenouil doux (Fruit), *Fr. Cod.*; Fruits (Semences) de Fenouil, *Fr.*; Fructus Fœniculi, P. G.; Fenchel, Fenchelsamen, G.; Finocchio, It.; Hinojo, *Sp.*

The plant producing fennel seed was attached by Linnæus to the genus *Anethum*, but was separated from it by De Candolle, and placed, with three or four others, in a new genus styled *Feniculum*, which has been generally adopted by botanists. The *Anethum Feniculum* of Linnæus embraced two varieties, the common or wild fennel, and the sweet fennel, the latter being the plant usually cultivated in the gardens of Europe. These are considered by De Candolle as distinct species, and named respectively *Feniculum vulgare* and *Feniculum dulce*, but the correctness of the opinion of the great Swedish botanist is now generally admitted.

Feniculum vulgare, De Cand., *Prodrom*. iv. 142.—*F. capillaceum*, Gilib., *Fl. Lithuan.* iv. 1782.—*Anethum Feniculum*, Linn.—*Feniculum Feniculum* (L.), Karst., Britton and Brown.—*F. officinale*, All.—*Meum Feniculum*, Spreng.—*Common Fennel* has a biennial or perennial tapering root, and an annual, erect, round, striated, smooth, green, and copiously branching

stem, which usually rises three or four feet in height. The leaves, which stand alternately at the joints of the stem, upon membranous striated sheaths, are many times pinnate, with long, linear, pointed, smooth, deep-green leaflets. The flowers are in large, flat, terminal umbels, with from thirteen to twenty rays, and destitute both of general and partial involucre. The corolla consists of five petals, which, as well as the stamens, are golden yellow. The fruit is ovate, rather less than two lines in length by about a line in breadth, and of a dark color, especially in the channels. The plant is a native of Europe, growing wild upon sandy and chalky ground throughout the continent, and is also abundant in Asia, possibly extending as far as China. The variety *F. officinale* of Mérat and De Lens is chiefly characterized by its fruit being twice as long as is that of the ordinary plant, and also a little curved, of a less dark color, with prominent ridges, and a persistent peduncle. It is sweeter and more aromatic than is common fennel seed. In India fennel is said to be obtained from *F. panmorium*, D.C., which is probably, however, only a variety of the official plant. Sicilian fennel is affirmed to be the fruit of *F. piperitum*.

F. dulce, De Cand., *Prodrom*. iv. 142.—*Sweet Fennel* bears a general resemblance to *F. vulgare*, but differs in having its stem somewhat compressed at the base, its radical leaves somewhat distichous, and the number of rays in the umbel only from 6 to 8. It is also a much smaller plant, being only about a foot high; its flowers appear earlier, and its young sweet shoots or turiones are eaten in Italy boiled or as a salad. According to Index Kewensis it is identical with *F. vulgare*.

The roots of fennel were formerly employed in medicine, but are generally inferior in virtues to the fruit, which is now the only portion recognized by either the U. S. or British Pharm. It is stated that manufacturers of the oil usually distil the whole plant. Commerce is partly supplied from the product of our own gardens; but much the larger portion of the medicine is imported from Europe, and chiefly, we have been informed, from Germany. During the winter of 1879 much of the seed in the German market was adulterated with fennel seed partially deprived of its oil. The fennel seed cultivated here is sweeter and more aromatic than that from abroad, probably in consequence of its greater freshness. Fennel seeds¹ (half fruits) are oblong oval, from one to three or four lines in length, flat on one side, convex on the other, not infrequently connected by their flat surfaces, straight or slightly curved, brownish or of a dark grayish-green color, with five prominent, obtuse, yellowish

¹ L. R. Stowell states that the centres of the prominent ridges of fennel fruit are small vascular bundles, surrounded by large clear cells, of which those near the vascular bundles are elongated and narrow, while those more distant are irregular in shape and have large oval communicating openings.

ribs or ridges on the convex surface. On section the vittæ, or oil tubes, are seen to be very well developed and to be situated one between each pair of ridges and two upon the flat face of each mericarp. "Mericarps usually separated, each 4 to 10 Mm. long, and 2 to 3 Mm. broad, more or less curved, with five prominent, light-colored primary ribs, otherwise smooth, yellowish- or brownish-green; pericarp containing an oil-tube between each two ribs, and two upon the flat side; odor and taste aromatic, anise-like." *U. S.* There are eight chief varieties of fennel known to European commerce, the fruits differing very much in size and considerably in taste. The table below, which was originally compiled by J. C. Umney, is sufficiently complete for the purposes of identification of these different varieties.

Schimmel & Co.'s Semi-Annual Report for April, 1897, gives as additional varieties of fennel—Aleppo, oil amounting to 0.75 per cent.; Macedonian, 3.4 to 3.8 per cent.; Moravian, 3 per cent.; Milanese, 4.2 per cent.; Roumanian, 4.6 per cent.; Spanish, amount not stated; and Syrian (Damascus), 1.6 per cent. Of these, the Syrian may be the same as that called Persian by Umney, and the Roumanian the same as that called Russian. Several additional varieties are also mentioned by Umney (*P. J.*, 58 (1897), p. 226), who states that the European varieties were almost entirely displaced by the East Indian seed and that the latter would probably be supplanted by the Japanese variety.

The odor of fennel seed is fragrant, its taste warm, sweet, and agreeably aromatic. It yields its virtues to hot water, but more freely to alcohol. The essential oil may be separated by distillation with water. (See *Oleum Fœniculi*.) From 960 parts of the seed Neumann obtained 20 parts of volatile and 120 of fixed oil.

Uses.—Fennel seed was used by the ancients. It is one of our most grateful aromatics, and in this country is much employed as a carminative, and as a corrigent of other less pleasant medicines, particularly senna and rhubarb. It is recommended for these purposes by the absence of any highly excitant property. An infusion may be prepared by introducing two or three drachms of the seeds into a pint

of boiling water. In infants the infusion is frequently employed as an enema for the expulsion of flatus.

Dose, of the bruised or powdered seeds, twenty grains to half a drachm (1.3 to 2.0 Gm.).

FRANGULA. U. S.

FRANGULA [Buckthorn]

(frân'gû-lâ)

"The dried bark of *Rhamnus Frangula* Linné (Fam. *Rhamnaceæ*), collected at least one year before being used." *U. S.*

Rhamni Frangulæ Cortex, *Br.* (1885); Frangula Bark; Alder Buckthorn; Ecorce de Bourdaine, Bour-gène, *Fr.*; Cortex Frangulæ, *P. G.*; Faulbaumrinde, *G.*; Cortecia di frangola, *It.*

R. Frangula, Linn., *B. & T.* 65.—*Frangula vulgaris*, Reichb.—*F. Alnus*, Mill.—The Alder Buckthorn is an erect glabrous shrub from ten to fifteen feet high, without thorns, with broadly ovate obtuse leaves, with the margins entire or slightly sinuate, the under side sometimes slightly downy, and the rather numerous lateral veins diverging equally almost from the whole length of the midrib. Flowers all hermaphrodite, two or three together in each axil, with the calyx teeth, petals, and stamens in fives. Fruit dark purple, the size of a pea. This plant grows in hedges and bushy places throughout Europe and Russian Asia, except in the far north.

It is probable that most of the species of the genus *Rhamnus* have cathartic properties. An article upon *R. Purshiana* will be found elsewhere, as it is official in both of the Pharmacopœias. The *R. catharticus*, Linn., or common buckthorn, grows in Europe along with the official species, and has become naturalized in this country. Its bark is probably often sold for the official article. It is distinguished by its more spreading, thorny habit, and its dioecious flowers, which are thickly clustered in the axils and have their parts in fours. The leaves also are more acute, have their margins

Fennel Fruits.

Variety.	Average Length.	Average Length of Vittæ in Transverse Section.	Average Breadth of Vittæ in Transverse Section.	Percentage of Oil.	Odor and Taste of Oil.
	Mm.	Mm.	Mm.		
1. French (sweet) . . .	7 to 8	.11	.04 to .05	2.1	Sweet, anise-like, and fatty.
2. French (bitter) . . .	4 to 5	.18 to .2	.07 to .08	Not distilled	
3. German (Saxon) . . .	8 to 10	.2 to .22	.07 to .08	4.7	Sweet and very camphoraceous.
4. Indian	6 to 7	.1	.03 to .04	.72	Sweet and anise-like.
5. Russian	4 to 5	.2	.04 to .05	4.8	Very camphoraceous.

8. Japanese	3 to 4	.15 to .16	.07 to .08	2.7	Very sweet and camphoraceous.

finely serrate and their lateral veins mostly proceeding from the proximal half of the midrib. The fruit is black.¹

Properties.—This bark is officially described as “in quills of variable length, frequently flattened or crushed; bark 0.3 to 1 Mm. thick, externally grayish-brown to purplish-black, with numerous lenticels and occasional patches of foliaceous lichens; inner surface smooth, minutely striated, brownish-yellow to deep brown; fracture short and of a purplish tint in the outer layer, fibrous and pale yellow in the inner layer; odor distinct; taste somewhat aromatic, sweetish, and bitter; when chewed, imparting to the saliva a yellow color. The powder should be free from stone cells, and the fragments are colored reddish by sodium hydroxide T.S.” *U. S.*

According to Schrenk (*Am. Drug.*, April, 1887), the bark of *Rhamnus Frangula* can be distinguished from that of *R. Purshiana* (*Casaca Sagrada*) by the absence of the irregular angular sclerenchymatous cells, which in *R. Purshiana* are wedged together in large com-

pact groups, increasing in size and number towards the surface, and causing the short fracture of the outer bark.

It is not certainly known which of the several bodies isolated from frangula bark is the purgative principle. The most important body, *frangulin*, the *rhamnoxanthin* ($C_{20}H_{30}O_{10}$) of Buchner and Binswanger, may be obtained by Phipson's process by macerating the bark for three or four days in carbon disulphide, then permitting the liquid to evaporate, exhausting the residue with alcohol, which leaves the fatty matter behind, evaporating the alcoholic liquid to dryness, and recrystallizing from ether. As thus obtained it is in fine yellow crystals, melting at about 226° C. (438.8° F.), and subliming in golden-yellow needles. It is insoluble in water, soluble in 160 parts of warm 80 per cent. alcohol, nearly insoluble in cold alcohol, soluble in hot fixed oils, petroleum benzin, and oil of turpentine. It communicates its color to cotton, silk, and wool. Faust (*A. Pharm.*, 187, 8) first proved the glucosidal character of frangulin by boiling it in alcoholic solution with hydrochloric acid, obtaining glucose and *frangulinic acid*, $C_{14}H_{10}O_4$. This forms fine microscopic needles of reddish color, fusing at 248° to 250° C. Liebermann and Waldheim (*Ber. d. Chem. Ges.*, 9, p. 1775) obtained in this decomposition instead of frangulinic acid *emodin*, $C_{15}H_{10}O_6$, which they consider to be trioxymethylanthraquinone. Frangulinic acid, on the other hand, would be a dioxyanthraquinone and an isomer of alizarin. Schwabe, in 1888, also found that *emodin* and *rhamnodulcite* were the decomposition products of *frangulin*, to which latter he gave the formula $C_{21}H_{20}O_8$, instead of that given above by Buchner. (Planchon et Collin, *Drogues Simples* (1896), vol. ii. 590.) E. Amweg has devised a method of separating the glucosides from frangula, casaca and rhubarb by extraction with solvents; he uses, 1, benzene; 2, a mixture of two parts of benzene, and one part of absolute alcohol, and 3, alcohol (60 per cent.) (*Ap. Ztg.*, 1897, 747). Kubly isolated a crude acid which, when purified, he termed *frangulinic acid*; Amweg regards this acid as a decomposition product and calls it *pseudo-frangulin*, this when hydrolyzed becomes *pseudo-emodin*. The emetic action of the green bark is attributed to a hydrolytic ferment, which is destroyed by heating. (*P. J.*, 1898, 24.)

Uses.—In its fresh state this drug is very irritant to the gastro-intestinal mucous membrane, producing, when taken in sufficient quantity, violent catharsis, accompanied by vomiting and much pain. During drying it is said to lose much of its irritant power, and the dried bark is affirmed to resemble rhubarb in its action; hence the direction that the bark should be at least one year old. A *decoction* (an ounce to the pint) may be used in tablespoonful doses, or a dessertspoonful of an *elixir*, made by mixing four fluidounces of the fluidextract with twelve of elixir of orange may be employed.

¹The berries, which are ripened in September, are of the size of a pea, round, somewhat flattened at top, black, smooth, shining, with four seeds in a green, juicy parenchyma. Their odor is unpleasant, their taste bitterish, acrid, and nauseous. Their blackish, expressed juice was formerly recognized in the *Br. Ph.* under the name of *Rhamni Succus*. It has the color, odor, and taste of the parenchyma, is reddened by the acids, and from deep green is rendered light green by the alkalis. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the color called by painters *sap-green*. The dried fruit of another species, *R. infectoria*, yields a rich yellow color, and is employed in the arts under the name of *French berries*. Fleury obtained a peculiar crystallizable principle, *rhamnin*; but he did not ascertain whether it possessed cathartic properties. (See *J. P. C.*, xxvii, 666.) Wickler obtained from the ripe fruit a principle which he called *cathartin*, and believes that the rhamnin of Fleury, which was obtained from the unripe berries, is converted into that principle and grape sugar as the fruit matures. (*Chem. Gaz.*, viii, 232.) Lefort (*J. P. C.*, 1866, p. 420) studied Fleury's rhamnin, and describes it as forming pale yellow, translucent tables. It is scarcely soluble in cold water, soluble in hot alcohol, insoluble in ether or carbon disulphide. It is very soluble in caustic alkalis, from which it is precipitated by mineral acids. He gives it the formula $C_{12}H_{12}O_6 + 2H_2O$. Lefort also found a principle, *rhamnegin*, soluble in cold water, but otherwise agreeing in properties with rhamnin. Schützenberger (1868) decomposed rhamnegin, proving it to be a glucoside, having the formula $C_{20}H_{30}O_{10}$, and yielding *rhamnetin*, $C_{16}H_{16}O_8$, and a sugar isomeric with mannite. Schützenberger also found a body isomeric with rhamnegin, and distinguished the two as *rhamnegin* and *β rhamnegin*, which, with Lefort's rhamnin, are present in buckthorn juice. Liebermann and Hörmann (*Ber. d. Chem. Ges.*, xi, (1878), pp. 952, 1618) confirm Schützenberger's results, and give the name of *xanthorhamnin* to his *rhamnegin*. They find his formula $C_{12}H_{10}O_6$ for rhamnetin to be correct, but get results that give for xanthorhamnin rather the formula $C_{14}H_{10}O_6$. Both the berries and their expressed juice are active hydragogue cathartics, apt to cause nausea and severe griping, and at one time much used in dropsy and also in rheumatism and gout. The dose of the recent berry is said to be about twenty grains (1.3 Gm.), of the dried, a drachm (3.9 Gm.), and of the expressed juice, a fluidounce (30 Cc.).

Among other species of *Rhamnus* which have claimed attention are *R. Wightii*, W. & A., a common shrub of Madras and Bombay (*P. J.*, Feb. 1888), and *R. californica*, Eschsch. (*R. humboldtiana*, Roem. & Schult.), of Mexico, which S. E. Sosa states sometimes produces paralysis in children (*El Estudio*, 1890). (See also *Rhamnus Purshiana*.)

Dose, of frangula, fifteen to thirty grains (1 to 2 Gm.).

Off. Prep.—Fluidextractum Frangulæ, U. S.

GALBANUM. Br.

GALBANUM ..

(gāl'ba-nūm)

"A gum-resin obtained from *Ferula galbaniflua*, Boiss. and Buhse, and probably from other species." Br.

Gummi-Resina Galbanum; Galbanum, *Fr. Cod.*; Galbanum, *P. G.*; Galban, Mutterharz, *G.*; Galbano, *It., Sp.*

It is uncertain from what plant galbanum is derived. At one time it was supposed to be the product of *Bubon Galbanum*, an umbelliferous plant of the eastern coast of Africa. It has also been referred to the *Ferula ferulago* of Linnæus, the *Ferula galbanifera* of Lobel, which inhabits the coast of the Mediterranean and is found also in Transylvania and the Caucasus. But no part of either of these plants has the odor of galbanum, and it is, therefore, scarcely probable that they yield the drug. Don, having found the seeds taken from a parcel of galbanum to belong to an undescribed genus of umbelliferous plants, and concluding that they came from the same source as the gum-resin itself, gave the title of Galbanum to the new genus, and named the species *Galbanum officinale*. This was rather hastily adopted by the London College; it is by no means certain that the same plant produced the seeds and the gum-resin. Specimens of a plant were received in England from Persia having a concrete juice adhering to them, which was taken by Lindley for galbanum, and that botanist, finding that the plant belonged to an undescribed genus, named it *Opoidia*, with the specific name *galbanifera*. Pereira, however, found the substance not to be galbanum, and this supposed origin of the drug, therefore, must be considered as extremely doubtful. A German traveller, F. A. Buhse, who has resided in Persia, stated that in 1848 he met with the *galbanum* plant on the declivities of the Demavend, near the southern coast of the Caspian. He saw the gum-resin exuding spontaneously from the plant, and was informed by the natives that the drug was collected from it. The plant is a *Ferula*, and has received the name of *F. galbaniflua*, Boissier and Buhse. Buhse also stated that the Persian galbanum is yielded by a second plant, which is doubtfully distinct from *F. galbaniflua*; this is the *F. rubricaulis*, Boissier (*F. erubescens*, Berg). Holmes is of the opinion (*P. J.*, 1891, 194) that "Levant" galbanum is yielded by *Ferula galbaniflua* and its variety *β-Ancheri*; that solid "Persian" comes possibly from *F. Schair*, Borsez.; while the liquid "Persian," judging from the fruits found in it, is derived from an undescribed species allied to *F. galbaniflua*.

It would also appear that the *F. Galbanum* of Aitchison is not identical with that of Boissier, and that neither this species nor *F. rubricaulis* yields galbanum, and that, further, all the varieties of galbanum of commerce come through Persia. Galbanum is said to be obtained by making incisions into the stem, or cutting it off a short distance above the root. A cream-colored juice exudes, which concretes upon exposure to the air. A portion of juice also exudes spontaneously from the joints, and hardens in the shape of tears. It was formerly official in the U. S. Pharmacopœia, but was dropped in the 1890 revision.

Properties.—Galbanum usually appears in the form of masses composed of whitish, reddish, or yellowish tears, from the size of a pin's head to that of a pea and larger, irregularly agglutinated by a darker colored yellowish-brown or greenish substance, more or less translucent, and generally mixed with pieces of stalk, seeds, or other foreign matters. It is also found, though rarely, in our markets, in the state of distinct roundish tears, about as large as a pea, of a yellowish-white or pale brownish-yellow color, shining externally as if varnished, translucent, and often adhering together. Galbanum has in cool weather the consistence of firm wax, but softens in summer, and by the heat of the hand is rendered ductile and adhesive. At 100° C. (212° F.) it is sufficiently liquid to admit of straining, and it generally requires to be strained before it can be used. A dark-brown or blackish color, a consistence always soft, the absence of whitish grains, a deficiency in the characteristic odor and taste, and the intermixture of earthy impurities are signs of inferiority. According to Hirschsohn (*Ph. Z. R.*, 1893, 353), galbanum of commerce differs from that formerly found in the market; its consistence is now like that of white turpentine, although the odor is still that of Levant galbanum; the greatest difference is shown in the action of strong acids and solvents on it. (See *A. J. P.*, 1893, 384.)

The odor of galbanum is peculiar and disagreeable; its taste bitterish, warm, and acrid; its sp. gr. 1.212. Triturated with water, it forms an imperfect milky solution, which on standing deposits the greater portion of what was taken up. Wine and vinegar act upon it in a similar manner. Alcohol dissolves a considerable proportion, forming a yellow tincture, which has the odor and taste of galbanum, and becomes milky with water, but affords no precipitate. In diluted alcohol it is wholly soluble, with the exception of impurities. Ether dissolves the greater portion. "When moistened with alcohol, galbanum acquires a purple color on the addition of a little hydrochloric acid." U. S. 1880. According to Conrady, the composition of galbanum is as follows: ethereal oil, 9.5 per cent.; resin, soluble in alcohol, 63.5 per cent.; and gum and impurities, 27 per cent. The purified resin was found by Conrady to

contain about 20 per cent. of combined *umbelliferone*, about 0.25 per cent. of free *umbelliferone*, and about 50 per cent. of *galbaresino-tannol*. This latter representative of the class of resino-tannols first established by Tschirch was proved to have the alcohol character by forming the acetyl and benzoyl derivatives. Conrady also considers that the *umbelliferone* is combined with this *galbaresino-tannol* in the form of an ester. The volatile oil he found to consist essentially of a hydrocarbon of the formula $C_{10}H_{16}$, with small amounts of a sesquiterpene, $C_{15}H_{24}$. The terpene has been identified as *d-pinene* by the terpin hydrate formation, while the sesqui-terpene, according to Wallach, is *cadinene*, identified by the formation of its chlorhydrate fusing at 117° to 118° C. (Gildemeister and Hoffman, *Aetherische Oele*, p. 753). When the oil is extracted by solvents it is free from acid reaction, but when distilled with steam it acquires an acid reaction, and notable quantities of isovaleric acid are developed. These fatty acids are probably bound up as esters in the cold extracted oil. (*A. Pharm.*, 232 (1894), 98.) The crude oil is dextrogyrate. The resin, constituting about 60 per cent., is very soft, and dissolves in ether or in alkaline liquids, even in milk of lime, but only partially in carbon disulphide. When heated with hydrochloric acid for some time, it yields *umbelliferone*, $C_8H_6O_3$, which may be dissolved from the acid liquid by means of ether or chloroform, and obtained on evaporation in colorless acicular crystals. The aqueous solution of *umbelliferone* exhibits, especially on addition of an alkali, a brilliant blue fluorescence, which is destroyed by an acid. If a small fragment of galbanum be immersed in water, a fluorescence will be produced by a drop of ammonia. *Asafetida* shows the same reaction, but ammonia does not.

Galbanum submitted to dry distillation yields a thick oil of brilliant blue color. This oil on rectification yields a greenish portion, and then a superb blue oil. Kachler (*Ber. d. Chem. Ges.*, 1871, p. 36) found a colorless oil, $C_{10}H_{16}$, and a blue oil, $C_{10}H_{16}O$, boiling at 239° C. The blue oil, according to Kachler, after purification, agrees with the blue oil of the flowers of *Matricaria Chamomilla*. By fusing galbanum resin with potassium hydroxide, Hlasiwetz and Barth (*Ann. Ch. Ph.*, 130, p. 354) obtained *resorcinol*, together with acetic and volatile fatty acids.

According to Ludewig, a gum-resin, designated as *Persian galbanum*, is received in Russia by the way of Astrakhan or Orenburg, and is the kind used in that country. It comes enclosed in skins, and is in masses of a reddish-brown color with whitish streaks, of a disagreeable odor, somewhat like that of *asafetida*, and of an unpleasant, bitter, resinous taste. It is so soft as to melt with a slight elevation of temperature. It differs from common galbanum in its odor, in its color, which is never greenish, and in the absence of

tears, and is probably derived from a different plant. It abounds in impurities. This variety of galbanum is probably the same as that obtained by Aitchison in Afghanistan, which on chemical examination yielded—volatile oil, 3.108 per cent.; resin (ether extractive, 61.2, alcohol extractive, 7.576), 68.776; water extractive (gum), 17.028; insoluble matter, 10.56. (*P. J.*, Dec. 11, 1886.)

Uses.—Galbanum was known to the ancients. It is stimulant, expectorant, and antispasmodic, and is considered as intermediate in power between ammoniac and asafetida. It has chiefly been used in chronic affections of the bronchial mucous membrane, *amenorrhœa*, and chronic *rheumatism*. It is occasionally applied externally as a plaster to *indolent swellings*, with the view of promoting resolution or suppuration.

Dose, from ten to twenty grains (0.65 to 1.3 Gm.), given in pill, or triturated with gum arabic, sugar and water, so as to form an emulsion.

GALLA. U. S., *Br.*

NUTGALL

(gāl'la)

"An excrescence on *Quercus infectoria* Olivier (Fam. *Cupulifera*), caused by the punctures and deposited ova of *Cynips tinctoria* Olivier." *U. S.* "Excrescences on *Quercus infectoria*, Olivier, resulting from the puncture and deposition of an egg or eggs of *Cynips Gallæ tinctoriæ*." *Br.*

Galls, Aleppo or Syrian Galls; *Galla Halepensis*, s. *Turcica*, s. *Levantica*, s. *Tinctoria*, s. *Quercina*; *Galle de Chêne*, d'Alep. *Fr. Cod.*; *Noix de Galle*, *Fr.*; *Gallæ*, *P. G.*; *Galläpfel*, *Gallen*, *G.*; *Noce di galla*, *It.*; *Agallia*, *Sp.*

Many plants, when pierced by certain insects, particularly those of the genus *Cynips*, are affected at the points of puncture with a morbid action, resulting in excrescences, which, as they are derived from the juices of the plant, partake more or less of its chemical character. Most of the oaks are occasionally thus affected, and the resulting excrescences, having in a high degree the astringency of the plant, have been employed for various practical purposes. They are known by the name of *galls*, a term which, as well as their use in medicine, has been handed down from the ancients. *Quercus infectoria*, *Q. ægilops*, *Q. excelsa*, *Q. Ilex*, *Q. Cerris*, and *Q. Robur* have been particularized as affording this product; but it is now generally admitted, on the authority of Olivier, that the official galls are derived chiefly, if not exclusively, from *Q. infectoria*.¹

¹ Under the name of *Chinese galls*, a product has been brought from China, supposed to be caused by an insect allied to the aphid, as such an insect has been found in the interior of them. They are irregularly spindle-shaped, often more or less bent, with obtusely pointed protuberances, about two inches long by an inch in diameter at the central thickest part,

Quercus infectoria, Willd., *Sp. Plant.* iv. 436; Olivier, *Voy. Orient.* t. 14 et 15; Carson, *Illustr. of Med. Bot.*, ii. 40, pl. 85.—*Q. lusitanica*, Lam., *Encyc.* i. 719.—*Q. leptocarpus*, Kotschy.—*Q. rigida*, Koch.—*Q. petiolaris*, Boiss.—The *dyer's oak* is a small tree or shrub, with a crooked stem, seldom exceeding six feet in height. The leaves are obtusely toothed, smooth, of a bright-green color on both sides, and stand on short footstalks. The acorn is elongated, smooth, two or three times longer than the cup, which is sessile, somewhat downy, and scaly. This species of *Quercus* grows, according to Olivier, throughout Asia Minor, from the Archipelago to the confines of Persia. M. Kinnier found it also in Armenia and Kurdistan; Hardwicke observed it growing in the neighborhood of Adwanie, and it probably pervades the middle latitudes of Asia.

The gall originates from the puncture of the *Cynips quercusfolii* of Linnæus, the *Diplolepis gallæ tinctoriæ* of Geoffroy, a hymenopterous insect or fly, with a fawn-colored body, dark antennæ, and the upper part of its abdomen shining brown. The insect pierces the shoots and young boughs, and deposits its egg in the wound. This irritates the part, and a small tumor quickly rises, which is the result of a morbid growth, exhibiting various cells under the microscope, but no proper vegetable fibre. The egg grows with the gall, and is soon converted into a larva, which feeds upon the vegetable matter around it, and thus forms a cavity in the centre of the excrescence. The insect at length becomes a fly, and escapes by eating its way out. The galls are in perfection when fully developed, before the egg has been hatched or the fly has escaped. Collected at this period, they are called, from their dark color, *blue, green, or black galls*, and are most highly esteemed. Those which are gathered later and

have been injured by the insect are *white galls*. They are usually larger, less heavy and compact, and of a lighter color than the former.

The galls collected in Syria and Asia Minor are brought to this country chiefly from the ports of Smyrna and Trieste, or from London. As they are produced abundantly near Aleppo, it has been customary to designate them by the name of that town, though the designation, however correct it may formerly have been, is now wholly inapplicable, as they are obtained from many other places, and the produce of different parts of Asiatic Turkey is not capable of being discriminated, at least in our markets. Great quantities of galls, very closely resembling those from the Mediterranean, have been brought to the United States from Calcutta. Royle states that they are taken to Bombay from Bussorah through the Persian Gulf. We are, nevertheless, informed that galls are among the products of Moultan. Those of France and other southern countries of Europe have a smooth, shining reddish surface, are little esteemed, on account of their small yield of tannin, and are seldom brought to the United States.

Properties.—Galls are "subglobular, 1 to 2 Cm. in diameter, externally blackish olive-green or blackish-gray, more or less tuberculated above, the basal portion nearly smooth and contracted into a short stalk, sometimes with a perforation on one side; heavy; fracture horny, yellowish or grayish; in the centre a cavity containing either the partly developed insect, or pulverulent remains left by it; nearly inodorous; taste strongly astringent." U. S. The best are externally of a dark bluish or lead color, sometimes with a greenish tinge, internally whitish or brownish, hard, solid, brittle, with a flinty fracture, a striated texture, and a small spot or cavity in the centre, indicating the presence of the undeveloped or decayed insect. Their powder is of a light yellowish gray. Those of inferior quality are of a lighter color, sometimes reddish or nearly white, of a loose texture, with a large cavity in the centre, communicating externally by a small hole through which the fly has escaped. The U. S. P. 1890 directed that "light, spongy, and whitish-colored Nutgalls should be rejected." Galls have a bitter, very astringent taste, and when whole are inodorous or nearly so, but bruised or in powder they have a decided and peculiar though not very strong odor. The tannin of galls, usually known as *gallo-tannic acid*, appears to exist in the galls, in part at least, as a glucoside, but one very easily broken up by ferments like pectase into glucose and *di-gallic acid*, $C_{14}H_{10}O_8$, which is the material, therefore, extracted from the galls. This *di-gallic acid* may be considered as the anhydride of *gallic acid*, $C_7H_6O_5$, formed from two molecules of this latter by the elimination of one molecule of water. Commercial tannin yields from 0 to 22 per cent. of glucose, showing the presence of varying amounts of the unaltered

of an ash color and a soft velvety feel, very light, hollow, with translucent walls about a line in thickness, of a slight odor recalling that of ipecac, and a bitter astringent taste. From an examination of fragments of leaves and petioles found among these galls, Schenck concluded that the tree on which they are found is a species of *Rhus*; but according to Decaisne, their true source is probably the *Distylium racemosum* of Zuccarini (*Flor. Japon.*, i. p. 178, t. 94), a large tree of Japan, the leaves of which produce a velvety gall, resembling the one in question. (Gibourt, *Hist. Nat. des Drogues*, 1850, iii. 703.) More recently, however, it has been asserted by Daniel Hanbury that this opinion of Decaisne is erroneous (P. J., Feb. 1862, p. 421), as in his examination of the packages imported from China and Japan he has found remains of different parts of a species of *Rhus*, but never any of a *Distylium*. Besides, the form of the galls of the *Distylium*, as figured by Siebold and Zuccarini, is entirely different. The species of *Rhus* which yields the commercial Chinese galls is the *R. semialata*, Murray. The Chinese make great use of this product both in dyeing and as a medicine. L. A. Buchner, Jr., has found it to contain 65 per cent. of tannic acid identical with that of the official galls. (*Ph. Ob.*, July, 1851, p. 526.) It is recommended by Stenhouse for the manufacture of gallic acid, being preferable for this purpose to the official galls, in consequence of its less amount of coloring matter. (P. J., Dec. 1862.) An inferior kind of galls is produced in great quantities in England, by the attack of the *Cynips kollari* of Hartig, upon the common English oak; but they have been ascertained to contain little tannic acid, and are of little value.

glucoside. Galls yield, on an average, from 65 to 77 per cent. of tannin. (See *Acidum Tannicum* and *Acidum Gallicum*, see also "The Tannins," by Henry Trimble, J. B. Lippincott Co., 1892.) All the soluble matter of galls is taken up by forty times their weight of boiling water, and the residue is tasteless. Alcohol dissolves seven parts in ten, ether five parts. (*Thomson's Dispensatory*.) A saturated decoction deposits upon cooling a copious pale-yellow precipitate. The infusion or tincture affords precipitates with sulphuric and hydrochloric acids, lime water, and ammonium and potassium carbonates, with solutions of lead acetate and subacetate, copper and iron sulphates, silver and mercury nitrates, and potassio-antimonyl tartrate; with solution of gelatin; and with the infusions of Peruvian bark, calumba, opium, and many other vegetables, especially those containing alkaloids, with most of which tannic acid forms insoluble compounds. The infusion of galls reddens litmus paper, is rendered orange by nitric acid, milky by mercuric chloride, and has its color deepened by ammonia, but yields no precipitate with either of these reagents. Zinc sulphate was said by A. T. Thomson to slowly occasion a precipitate, but this result was not obtained by Duncan. Infusion of galls is rendered more permanent by the addition of 10 per cent. of glycerin.

A variety of galls was imported into Germany, which was said to be derived from Central Asia, especially from the provinces of Khokan, Khiva, and Bokhara, where they are used in dyeing. They are of various forms, some being long, others round, cylindrical, or angular, and sometimes they are grouped upon a single stalk, and covered with little elevations. They differ from all other galls by their color, being on one side yellow, and on the other of a fine red. Most of them present a little opening, and in the interior are eggs and larvæ of a peculiar species of aphid. They have yielded, on analysis, 43.10 per cent. of tannin, 3.03 of a green wax, 16 of cellulose, and an undetermined quantity of fecula and volatile oil. (R. Palne, *J. P. C.*, Avril, 1873.)

Uses.—Galls have a powerfully astringent action, but are no longer prescribed internally.¹

Off. Prep.—*Tinctura Gallæ, U. S.*; *Unguentum Gallæ, U. S., Br.*; *Unguentum Gallæ cum Opio, Br.*

¹ *Aromatic Syrup of Galls.*—The following old formula, based upon one of Physick's, is still sometimes employed. Macerate for twenty-four hours half an ounce of powdered galls, two drachms of bruised cinnamon, and two drachms of bruised nutmeg, in half a pint of brandy; then percolate, and, when the liquor has ceased to pass, add enough diluted alcohol to yield half a pint of filtered liquor. Put this into a shallow capsule, suspend over it two ounces of sugar on a slip of wire gauze, and set the tincture on fire. The sugar melts with the flame, and falls into the liquid beneath. When the combustion ceases, agitate and filter. A highly astringent aromatic syrup is obtained, a fluidrachm of which may be given in diarrhoea. (*A. J. P.*, xxvii. 416.)

GAMBIR. U. S. (Br.)

GAMBIR [Pale Catechu]

[To replace Catechu, Pharm. 1890]

(gām'bīr)

"An extract prepared from the leaves and twigs of *Ouroparia Gambir* (Hunter) Baillon (*Fam. Rubiaceæ*)." *U. S.* "An extract of the leaves and young shoots of the *Uncaria Gambier, Roxb.*" *Br.*

Catechu, Br.; *Catechu Pallidum, Terra Japonica, Gambier, Cutch*; *Gambir Cubique, Fr.*; *Catechu, P. G.*; *Katechu, Gambir-Catechu, G.*; *Catechu, It., Sp.*

Ouroparia Gambir (Hunter), Baillon; *Uncaria Gambier, Roxb.*; *Nauclea Gambir, Hunter*.² This is a climbing shrub with slender stems somewhat thickened at the nodes, cylindrical or occasionally slightly angular; leaves ovate or oblong, entire, three to four inches long, rounded at the base but abruptly attenuated at the apex, opposite and stipulated, smooth on both sides. The flowers are small, crowded into a dense globular head on a hairy receptacle; the flower heads are borne on long axillary peduncles which bear in the middle a whorl of bracts. At the point where these bracts occur the peduncle breaks after the falling of the inflorescence and the remainder of the peduncle becomes elongated and curved into hooks by means of which the plant climbs. Corolla gamopetalous, trumpet-shaped, tube slender, $\frac{1}{2}$ inch long, flaring and five-lobed at the summit; stamens five, inserted on the throat of the corolla; ovary inferior, 2-celled; style long, protruding beyond the corolla; calyx 5-lobed, woolly; fruit one inch long, pericarp dry, dehiscing vertically into two valves; seeds very numerous.

It is a native of Malacca, Sumatra, Cochin-China, and other parts of Eastern Asia, and is largely cultivated in the islands of Bintang, Singapore, and Prince of Wales. The gambir is prepared by lopping off the leaves, shoots, and twigs of the plant, chopping them into pieces, and throwing them into an iron pot filled with boiling water. When the leaves are exhausted and the liquid sufficiently thick, it is poured into small wooden tubs, and so soon as sufficiently cool, a half closed hand is plunged into the semi-fluid mass and a piece of light wood shaped like an elongated dice box rapidly worked up and down in the hollow formed by the hand. The extract begins to thicken by a process which is compared to crystallization. The mass is finally turned out, and cut into cubes, which are put upon trays and smoke-dried. (See also *P. J.*, 1892, 1003.) This extract, which is known by the native Malays as *pinang* or *siren* was first brought to the attention of the profession by Campbell.

² The full synonymy of this plant is exceedingly complex. The *Index Kewensis* makes the genera *Ouroparia*, *Aglyophora*, *Uncinaria*, all synonyms of *Uncaria*. The British Pharmacopœia follows the *Index Kewensis*, but the *Ouroparia* of Aublet antedates the *Uncaria* of Schreber by fourteen years.

Properties.—Gambir is in “irregular masses, or cubes about 25 Mm. in diameter; externally reddish-brown, pale brownish-gray, or light brown; fracture dull-earth, friable, crystalline; inodorous, bitterish, very astringent, with a sweetish after-taste; free from starch. Not less than 70 percent. should be soluble in alcohol; when incinerated, Gambir should not yield more than 5 percent. of ash.” *U. S.* “Catechu should not afford any characteristic reaction with the tests for starch, and should not yield more than 5 per cent. of ash when incinerated.” *Br.* It is light and porous, so that it floats when thrown in water. It is partially soluble in cold water, and almost wholly so in boiling water, which deposits a portion upon cooling. Duhamel, Ecky, and Procter dissolved 87.5 per cent. of it in cold water by means of percolation. (*A. J. P.*, xvi. 166.) Nees von Esenbeck found it to consist of from 36 to 40 per cent. of *catechutannic acid*, a peculiar principle called *catechuin*, *catechin*, or *catechuic acid*, gum or gummy extractive, a deposit like cinchonic red, and 2.5 per cent. of lignin. *Catechin*, when perfectly pure, is snow-white, of a silky appearance, crystallizable in fine needles, melting at 217° C., unalterable in the air if dry, fusible by heat, very slightly soluble in cold water, with which it softens and swells up, soluble in boiling water, which deposits it on cooling, and soluble also in alcohol and ether. It very slightly reddens litmus paper, and, though coloring solution of chloride of iron green, and producing with it a grayish green precipitate, differs from tannic acid in not affecting a solution of gelatin. The very great discordance of different authors as to its formula seems to be explained by some experiments of Etti (*Ann. Ch. Ph.*, 186, p. 327), who showed that *catechin*, $C_{15}H_{12}O_6$, readily gives at 100° C. (212° F.), or even when kept for some time over sulphuric acid, an anhydride, $C_{15}H_{10}O_5$, and at 160° C. (320° F.) a second anhydride, $C_{15}H_{10}O_4$, which, mixed in varying proportions, explain the varying results. Gautier (*Bull. Soc. Chim.*, 30, 567) finds three different catechins separable by their different solubility in water, all of them crystallizable. These are: *a-catechin*, $C_{15}H_{12}O_6 + 2H_2O$, melting at from 204° to 205° C., and present in gambir to the amount of 12 per cent.; *b-catechin*, $C_{17}H_{18}O_6 + H_2O$, melting at from 176° to 177° C., and 2 per cent. present in gambir; and *c-catechin*, $C_{15}H_{12}O_6 + H_2O$, melting at 163° C., and present in gambir to the amount of 6.5 per cent.

Perkin and Yoshitako (*P. J.*, 1902, p. 530) have made an elaborate investigation of gambir and acacia catechus. They find three catechins, designated respectively as (a), (b), and (c). Catechin (b), $C_{15}H_{12}O_6 + 4H_2O$, occurs in air dried, colorless needles, melting at 175° to 177° C., and gives on fusion with alkali, phloroglucinol, protocatechuic acid, and an acid resembling acetic acid. Catechin (c), $C_{15}H_{12}O_6$, air dried, contains no water of crys-

tallization and forms colorless prisms, melting at 235° to 237° C. Catechin (a), $C_{15}H_{12}O_6 + 3H_2O$ (or less probably $C_{14}H_{14}O_6 + 3H_2O$), air dried, forms colorless needles, melting at 204° to 205° C.

Good gambir should occur in a hard compact mass, breaking up, when the adhering mat is removed, into distinct cubes of a brownish-black color externally, and a deep mahogany-red with an occasional streak of yellow internally. It should not steam when the mat is opened. From this quality it grades down to a stuff which has been prepared by mixing the material obtained by reboiling the exhausted leaves with various mixtures. This lowest grade is not in cubes, steams when opened, frequently shows large patches of black or dirty blue color, and often has a sour fetid odor; its color varies from black to light-brown.

The varieties between the two extremes are very great; sometimes gambir occurs in solid mass of fair quality; sometimes the cubes are of extraordinary size, and of a color varying from a dirty white to very pale yellow. The finer varieties of gambir vary in physical characteristics; sometimes it is in oblong instead of cubical pieces, without differing in other respects from the ordinary kind; sometimes in small circular cakes, or short cylindrical pieces, heavier than water, of a pale reddish-yellow color, moderately astringent, gritty under the teeth, and quite impure; sometimes in very small cubes, distinguishable by the black color they afford with tincture of iodine, indicating the admixture of sago or other amylaceous matter; and, finally, in circular cakes of the size of a small lozenge flat on one side and somewhat convex on the other, of a pale pinkish yellowish-white color, and chalky to the touch. This is most highly esteemed by the natives in India. (Pereira.) At the Edinburgh Forestry Exhibition in 1885 the Maharajah of Johore exhibited specimens labelled “gambir produced in Johore.” The first quality, which was “*makan*” (for eating), was in regular cubes, externally cassia-brown color, internally pale cinnamon brown, and yielded 32 per cent. of tannic acid; the second quality was in badly formed cubes, externally brown and black, internally cinnamon, and yielded 30 per cent. of tannic acid; the third quality was in dull-brown, well-shaped cubes, internally pale brown, and yielded 19 per cent. of tannic acid. The oblong or *parallelopiped gambir* was of a uniform dull brown, very hard and strong, and yielded only 2 per cent. of tannic acid. MacEwan believes that the low percentage of tannin was due to the decoction not having been subjected to prolonged boiling, which favors the decomposition of catechin, with the formation of catechutannic acid. None of the finest varieties of gambir, such as are used by the natives for chewing, occur to any extent in American commerce. Prebble records his examination of a cube gambir of fine appearance which contained a large percentage of starch. (*P. J.*, 1893, 21.)

Enormous quantities of gambir are used both in Europe and America in tanning, calico printing, dyeing, and other art processes requiring tannic acid.

Uses.—Gambir is a serviceable remedy in those cases where astringents are indicated. The complaints to which it is best adapted are *diarrhœa* dependent on debility or relaxation of the intestinal mucous membrane, and *passive hemorrhages*, particularly from the uterus. A small piece held in the mouth and allowed slowly to dissolve is an excellent remedy in *relaxation of the uvula* and the *irritation of the fauces* and *troublesome cough* which depend upon it. Applied to *spongy gums*, in the state of powder, it sometimes proves useful; and it has been recommended as a dentifrice in combination with powdered charcoal, Peruvian bark, myrrh, etc.

Dose, from ten grains to half a drachm (0.65 to 2.0 Gm.), which should be frequently repeated, and is best given with sugar, gum arabic, and water.

GELATINUM. U. S., Br.

GELATIN

(gē-lăt'-nūm)

"The purified air-dried product of the hydrolysis of certain animal tissues, as skin, ligaments, and bones, by treatment with boiling water." *U. S.* "The air-dried product of the action of boiling water on such animal tissues as skin, tendons, ligaments, and bones." *Br.*

Gelatine; Gélatine animale, *Fr. Cod.*; Colle de Flandre purifiée, *Fr.*; Gelatina alba, *P. G.*; Weisses Leim, *Gallerte*, *G.*; Gelatina, *Sp.*

Gelatin is the term applied to purified forms of the substance ordinarily known as glue, and the bones and animal matter from which the best qualities of gelatin are prepared are carefully selected so as to be free from decomposed products and odorous substances. The hot solution of gelatin must be thoroughly clarified if the so-called sparkling gelatin is to be made. The surface of sheet gelatin is covered with lozenge-shaped marks, due to impressions left by the knotted netting upon which it is dried. Shred gelatin is made by cutting sheet gelatin into very narrow shreds by a shearing-machine. (See *Nat. Drug.*, 1894, 134.) *Gelatose* and *paragelatose* are terms used by Dastre and Floresco to define gelatin which has lost its power of "gelatinization" through the action of ferments or microbes, saline solutions, or the prolonged action of boiling water. (*P. J.*, 1895, 454.)

Properties.—It is officially described as "an amorphous, more or less transparent solid, usually shredded or in thin sheets; colorless or with a slight yellowish tint, inodorous, and

having a slight, characteristic, almost insipid taste. Unalterable in the air when dry, but putrefying rapidly when moist or in solution. When incinerated, Gelatin is decomposed, leaving a slight mineral residue, which should not exceed 2 percent. of the original weight. Gelatin is insoluble in cold water, but swells and softens when immersed in it, gradually absorbing from 5 to 10 times its weight of water. It is soluble in boiling water, acetic acid, and glycerin; insoluble in alcohol, ether, chloroform, benzene, carbon disulphide, and fixed and volatile oils. When dissolved in boiling water (1 in 50), it should solidify upon cooling, and form a transparent jelly. An aqueous solution of Gelatin (1 in 5000) is at once rendered turbid on the addition of tannic acid T.S., the precipitate being insoluble in the presence of an excess of the reagent. Gelatin is precipitated from its aqueous solution by mercuric chloride T.S. in excess; it is not precipitated by a solution of alum, by ferric chloride T.S., or by lead acetate T.S. If potassium dichromate T.S. be added to a solution of Gelatin in hot water, the jelly which forms on cooling becomes insoluble in warm water after exposure to light." *U. S.* "In translucent and almost colorless sheets or shreds. A solution in 50 parts of hot water is inodorous, and solidifies to a jelly on cooling. Gelatin is insoluble in alcohol (90 per cent.) and ether. It dissolves in acetic acid. Its aqueous solution yields a precipitate with solution of tannic acid, but not with solutions of other acids, nor with solution of alum, solution of lead acetate, or test-solution of ferric chloride." *Br.*

Gelatin is largely used for making capsules. Certain medicines are so offensive to the taste, and consequently so likely to cause nausea, that it is highly desirable to administer them in such a way as to prevent their contact with the tongue and palate. This object is fully accomplished, so far as regards many disagreeable liquid medicines, by the use of the capsules of gelatin. A polished bulb of iron, ivory, or bone, of the size and shape of the capsules required, and connected by a slender rod with a handle, is first greased by rubbing with an oiled cloth, and then dipped into a solution of gelatin made by heating six parts of pure gelatin with one of sweetened water. Upon being withdrawn, it is held for a short time so as to allow the excess of the solution to run off, and then fixed with the handle in a board, the coated bulb being upward, until the coating becomes cold and firm. The capsule is now removed by the fingers, and further dried by exposure on a tray. A number of capsules having been prepared, they are placed each in a small cell upon a board, with their mouths upward, and the liquid they are to contain is introduced by means of a syringe with a fine point. Their mouths are then closed with a drop of the solution of gelatin applied by means of a stick or glass rod, which is afterwards strengthened by an additional coating, given by

dipping the mouth of the capsule into the solution diluted with a little water. (*Redwood's Supplement*, p. 664.) The capsules may be made of such a capacity as to contain from ten to fifteen grains of copaiba or other liquid. Capsules are now largely used for enclosing dry powders like quinine, etc. These are ovoid in shape, and after being filled with the powder by the pharmacist, are closed by putting upon the open end a rounded gelatin cap and pressing it down tightly. When so-called *soft capsules* are desired, a small quantity of glycerin is introduced into the gelatin mass; this makes the film elastic by preventing its drying completely.

Uses.—The experiments of Dastre and Floresco (*C. R. S. B.*, 1896, ii.; iii.), which have been confirmed by a number of observers, show that gelatin has the power of greatly increasing the coagulability of the blood. According to H. C. Wood, Jr. (*Am. Med.*, 1902, iii.), this property is not destroyed by digestion. This coagulating action has been taken advantage of in the treatment of *aneurism* and *hemorrhage*. The results in aneurism have, however, not been entirely encouraging. In hemorrhages not too acute, as *menorrhagia* or moderate *hemoptysis*, the gelatin may be successfully given by mouth in the form of a 10 per cent. jelly. In severe types of bleeding, as *hematemesis*, it may be given hypodermically in warm physiological salt solution. Great care must be observed in its hypodermic use, as several cases of fatal tetanus have followed this treatment. For hypodermic use only the especially prepared *Gelatinum Sterilizatum pro injectione*, which is now marketed by several manufacturing houses, should be employed. It is asserted that the remedy is useful also as a local styptic in *epistaxis*:

Dose, one-half to one ounce (15.5 to 31 Gm.).

GELATINUM GLYCERINATUM. U. S.

GLYCERINATED GELATIN

(gē-lăt'-nūm glŷc-ē-rj-nă-tūm)

Gelatina Glycerinata, Gelatinum Glycerini; Glycerin Jelly; Gelée Glycerinée, Fr.; Glycerinleim, G.

* "Gelatin, one hundred grammes [or 3 ounces av., 231 grains]; Glycerin, one hundred grammes [or 3 ounces av., 231 grains], Water, a sufficient quantity, to make two hundred grammes [or 7 ounces av., 24 grains]. Pour upon the Gelatin sufficient Water, which has been previously boiled and cooled, to cover it; allow it to stand one hour; pour off the Water and allow the Gelatin to drain for a few minutes; then transfer it to a tared dish, add the Glycerin, and heat it on a water-bath until the gelatin is dissolved. Strain the solution while hot, and continue to heat on the water-bath until the product weighs two hundred grammes [or 7

ounces av., 24 grains]. When cold, cut the mass into pieces, and preserve these in suitable containers." U. S.

This preparation was made official for the first time in the U. S. Pharm. (8th Rev.).

Uses.—Glycerinated gelatin is used solely as a vehicle in making gelatin suppositories, bougies, etc. (See *Suppositoria*.)

GELSEMIUM. U. S. (Br.)

GELSEMIUM

(gēl-sēm'ŭm)

"The dried rhizome and roots of *Gelsemium sempervirens* (Linné) Aiton filius (Fam. *Loganiaceæ*)." U. S. "The dried rhizome and roots of *Gelsemium nitidum*, Michaux." Br.

Gelsemii Radix, Br., *Gelsemium Root*, Yellow Jasmine, Yellow Jessamine, Carolina or American Yellow Jessamine, Yellow or Evening Trumpet Flower; *Gelsemium*, Fr. *Cod.*; *Jasmin sauvage*, Fr.; *Gelsemie*, Giftjasmin, G.; *Gelsemio*, Sp.

Gelsemium sempervirens (L), Ait. f., Britton and Brown; also Ait. f. (1211).—*Bignonia sempervirens*, L. (1753).—*Gelsemium nitidum*, Michx. (1803).—*G. lucidum*, Poiv.—The yellow or Carolina jasmine is one of the most beautiful climbing plants of our Southern States,¹ ascending lofty trees, and forming festoons from one tree to another, and during its flowering season, in the early spring, scenting the atmosphere with its delicious odor. The stem is twining, smooth, and shining; the leaves perennial, opposite, shortly petiolate, lanceolate, entire, dark green above, and paler beneath; the flowers in axillary clusters, large, of a deep-yellow color, and fragrant, with a very small, five-leaved calyx, and a funnel-shaped corolla, having a spreading, five-lobed, nearly equal border. The fruit is a flat, compressed capsule, divisible into two parts, two-celled, and furnished with flat seeds, which adhere to the margins of the valves. The plant grows in rich, moist soils along the sea-coast from Virginia to the south of Florida. The flowers are said to be poisonous. *Gelsemium elegans*, Benth., of upper Burma is an extremely poisonous creeper which contains gelsemine or an allied alkaloid.

Properties.—As we have seen it in commerce, the rhizome is sliced into pieces, about an inch in length, cylindrical or split, very light and fibrous, of a dirty yellowish-white color, but darker where the epidermis remains, of a slight, feebly narcotic odor, and a bitterish, not unpleasant taste. It is officially described as "cylindrical, usually in cut pieces of variable length, from 5 to 20, or even 30 Mm. in diameter; externally light yellowish-brown, with purplish-brown longitudinal lines; fracture of the rhizome splintery, the roots breaking with one-half the fracture transverse, the other half

¹ This official plant must not be confounded with the true yellow jasmine of Madeira, often planted in the Southern States, which is the *Jasminum odoratissimum*, L., which also has very fragrant yellow flowers.

oblique or short-splintery; bark about 1 Mm. thick; wood pale yellow, porous, but tough, with numerous distinct medullary rays, in the rhizome excentric, and with four groups of internal phloem; odor pronounced, characteristic; taste slightly aromatic, bitter." *U. S.* A microscopic character, said by Rothrock to be diagnostic, is the more or less complete division of the pith into four parts by plates of large, thin-walled cells. (*A. J. P.*, 1884.) For elaborate study of structure of gelsemium, see *A. J. P.*, 1898, 398; *A. J. P.*, 1899, 422; *D. C.*, 1901, 244. Sayre (*A. J. P.*, 1897, 8) found specimens of the root mixed with considerable proportions of the stem. Ingham (*A. J. P.*, 1897, 234) found that there was not much difference between the root and rhizome in alkaloidal value, but the stem does not appear to contain either gelsemine or gelsemic acid. (See also *A. J. P.*, 1897, 140.) Gelsemium yields its virtues to water, and readily to diluted alcohol. Analyzed by Henry Kollock, it was found to contain gum, starch, pectic acid, albumen, gallic acid, fixed oil, a fatty resin, a dry acrid resin, yellow coloring matter, volatile oil, extractive, lignin, a peculiar alkaloid called *gelsemine*, potassium, calcium, and magnesium salts, iron, and silica. The alkaloid, however, was not obtained sufficiently pure to admit of a full investigation of its properties. (*A. J. P.*, xxvii.) After Kollock's experiments, the alkaloid was obtained in a crystalline form, but still impure, by Maisch, from a tincture of the root, by a process of which a very brief abstract is given in *A. J. P.*, 1869, by C. L. Eberle, who in the same paper publishes the results of his own investigation. Eberle not only extracted gelsemine, but also satisfactorily established its alkaline properties, and proved that it was not contained in the wood of the root. Soon afterwards, the chemistry of yellow jasmine was more thoroughly investigated by Theo. G. Wormley. (*A. J. P.*, 1870.) He obtained pure gelsemine from the root and a peculiar acid, which he called *gelseminic* (gelsemic) acid.

Gelsemic or Gelseminic Acid.—Wormley obtained the acid from a fluidextract of the root, which is actually a concentrated tincture, by evaporating it on a water bath to about one-eighth of its volume, adding to the residue several times its bulk of pure water, allowing the mixture to stand until the supernatant liquid is nearly or quite clear, then transferring to a filter, washing the solids well with water, and reducing the filtrate thus obtained, together with the washings, on a water bath, to about the volume of the concentrated fluidextract. To this, filtered if necessary, hydrochloric acid is added in the proportion of a drop of the pure acid to each fluidounce of the original fluidextract; the acidulated liquid is then agitated with twice its volume of ether; and, after the liquids have separated, the ethereal portion is decanted, the aqueous liquid again agitated with a similar quantity of ether, which is in its turn

decanted, and the aqueous part finally washed with about its volume of ether. On mixing the ethereal liquids thus obtained, and allowing them to evaporate spontaneously, the gelsemic acid is left, chiefly in the form of nearly colorless groups of crystals, together with more or less yellowish or brownish resinous matter. From this the crystals are separated by washing with a little cold absolute alcohol, which dissolves the resin, with but a little of the crystals.

To purify the crystals further, they are mixed with a little hot water, and extracted from the mixture when cool by chloroform, which, on spontaneous evaporation, yields them nearly if not quite colorless. The acid, when pure, is colorless, inodorous, almost tasteless, and readily crystallizable, usually in groups or tufts of fine needles. The action of concentrated nitric acid may be considered as a test. If a drop of this acid be added to gelsemic acid or any of its salts, it forms a yellow, reddish, or red solution, which, if treated with ammonia in excess becomes of a deep blood-red color, lasting for hours. The one-thousandth of a grain will exhibit these changes. Potassium, sodium, or ammonium hydroxide, added to the acid, cause it to become intensely yellow, and form with it highly fluorescent solutions. The acid is fusible, and, at a high heat, volatilizable without change. Robbins (*Deut. Chem. Ges.*, 1876, 1182), who has also investigated gelsemic acid, states that it is identical with *æsculin* (the glucoside of the horse-chestnut), and gives it the formula $C_{15}H_{16}O_8 + 1\frac{1}{2}H_2O$. Dragendorff and Schwartz both believed with Robbins that gelsemic acid was identical with *æsculin*.

The subject was (*A. J. P.*, July, 1882) re-investigated by Wormley, who found that gelsemic acid differs from *æsculin* in the following well-marked particulars: 1, in crystallization, the gelsemic acid crystallizing much more readily; 2, in solubility, the gelsemic acid being more soluble in ether and less soluble in water than *æsculin*; 3, gelsemic acid is not soluble in hydrochloric acid, while *æsculin* is; 4, corrosive sublimate gives a copious yellow precipitate with gelsemic acid, while it gives no result with *æsculin*; 5, copper sulphate and lead acetate yield precipitates with gelsemic acid differing from those of the same reagents with *æsculin*. The conclusion of Wormley, that they are "very different substances," has been confirmed by Coblenz. (*Proc. A. Ph. A.*, 1897, 225.) He found that gelsemic acid was not a glucoside, as it remained unchanged after prolonged boiling with diluted acids, no reaction with phenylhydrazine being obtainable. Coblenz explains Robbins' reaction with Fehling's solution by showing that gelsemic acid has active reducing powers upon copper, silver, mercury, and other similar metallic salts. The differences between it and *æsculin* may be thus summarized: *Æsculin*, formula $C_{15}H_{16}O_8 + 1\frac{1}{2}H_2O$, melts at 160° C.; gelsemic acid, formula $C_{15}H_{16}O_8$, melts at 206° C.; *æsculin* forms a penta-acetyl derivative melting at from 203° to 206° C.; gel-

semic acid forms a diacetyl derivative melting at 180°C .; *æsculin* splits up into sugar and *æsculetin*; gelsemic acid does not hydrolyze; *æsculin* forms a bromine derivative melting at from 193° to 195°C .; gelsemic acid forms a bromine derivative melting at 250°C .

E. Schmidt believes that Wormley's gelsemic acid is identical with *scopoletin* derived from *scopola* root, and gives the name as β -methyl-*æsculetin*, $\text{C}_8\text{H}_8(\text{CH}_3)\text{O}_4$.

Coblentz found that one part of gelsemic acid was soluble in 1490 parts of distilled water at 30°C ., in 415 parts of absolute ether at 22°C ., in 135 parts of chloroform at 24°C ., and readily soluble in hot alcohol and glacial acetic acid.

Gelsemine.—This may be obtained, according to Wormley, from the concentrated extract from which gelsemic acid has been separated by ether, by rendering it slightly alkaline with potassium hydroxide (Schwartz prefers sodium hydroxide solution on account of the too great energy of the potassium hydroxide), then agitating repeatedly with chloroform, which dissolves the alkaloid with some impurities, and yields it, when evaporated at a very moderate heat, in the form of a hard, gum-like, yellowish or brownish-yellow solid. If this be treated with a little water, and acidulated with hydrochloric acid, it yields the alkaloid with some impurities to the liquid, which, if now filtered, evaporated to about one-sixteenth by volume of the original fluidextract employed, and then treated with a slight excess of potassium hydroxide, will give up the alkaloid in the form of a more or less white precipitate. This, upon being separated, and allowed to dry, shrinks greatly, and becomes dark. To purify it, the dry mass is powdered, and dissolved, with the aid of a few drops of hydrochloric acid, in a little water, from which the alkaloid is precipitated by a slight excess of potassium hydroxide, and then taken up by ether, which leaves it, on spontaneous evaporation, in the state of a very hard, brittle, and transparent mass, strongly adhering to the surface of the vessel employed. If now detached and pulverized, it forms a powder nearly or quite colorless. If still colored, it may be again treated with ether. Gelsemine was obtained in a much purer state than had been previously made by A. W. Gerrard. (*A. J. P.*, 1883, p. 258.) It is a brittle, transparent solid, crystallizing with difficulty from alcohol. Boiling water sparingly dissolves it. It softens at 38°C ., and fuses at 45°C . The pure base gives no color reaction with strong nitric acid, and the mixture is scarcely changed in color by heating. Strong sulphuric acid has no apparent action upon it; but if to the mixture a little manganic oxide be added and then rubbed with a glass rod, a deep crimson-red is obtained, passing to green. This reaction is so delicate that it can be demonstrated with a solution of 1 in 100,000. If this reaction be performed upon the pure alkaloid, the color may be suf-

ficiently intense to cause it to be mistaken for strychnine, but if a parallel experiment be carried on with strychnine, the two alkaloids cannot be mistaken, for the strychnine gives an intense purple, passing to red. Gerrard analyzed the alkaloid with care, and gives the formula $\text{C}_{12}\text{H}_{14}\text{NO}_2$ as its correct composition. F. A. Thompson (*Ph. Era*, 1887, p. 3) announced the presence of a second alkaloid, which he called *gelseminine*. After obtaining a solution of the alkaloids as sulphates he agitates it with an alkali and ether; the ethereal solution is shaken with water acidulated with hydrochloric acid, and the alkaloids are converted into hydrochlorides; gelseminine hydrochloride being easily soluble, and gelsemine hydrochloride less soluble, the latter is deposited on standing, and may be obtained pure by repeated crystallizations. He asserts that gelseminine differs greatly in physical and chemical properties from gelsemine, but, as he did not succeed in obtaining it absolutely pure, did not give the differences.

According to Cushny "*Gelsemine* is only slightly active, inducing the same symptoms in frogs as strychnine, but having no effect on mammals, even when injected into a vein in very large quantity. *Gelseminine*, on the other hand, is a powerful poison which resembles conium in most of its effects. The action of gelsemium is undoubtedly due to gelseminine and not to gelsemine, as far as mammals are concerned.

The pupils are very widely dilated by gelseminine when a solution is applied locally to the eye, much less so in general poisoning, in which the respiration generally fails before the pupil is fully dilated. The power of accommodation is also entirely lost when gelseminine or gelsemium tincture is applied to the eye."

Uses.—Gelsemium¹ produces in the healthy adult agreeable sensations of languor, with muscular relaxation, so that the subject finds some difficulty in moving the eyelids and keeping the jaws closed. More largely taken, it occasions dizziness, dimness of vision, dilated pupil, general muscular debility, and universal prostration, reducing the frequency and force of the pulse, and the frequency of respiration. After very pronounced poisonous doses the symptoms which have just been enumerated are intensified: double or impaired vision, ptosis,

¹ Gelsemium is said to have been long popularly employed as a vermifuge in the Southern and South-western States; but its more valuable properties have been known but a few years. Their discovery was accidental. A planter of Mississippi, laboring under an obstinate bilious fever, directed his servant to get a particular root from the garden and prepare a tea from it. The tea was prepared accordingly, and drunk by the invalid, who was soon afterwards affected with great prostration, and especially muscular debility, so that he could not raise a limb, but without stupor. These effects gradually passed off, and with them the fever. The servant had made a mistake in the root, and dug that of the gelsemium instead of the one intended. The planter, having made this discovery, employed the root afterwards with success upon his own plantation and in the neighborhood. The remedy passed into the hands of irregular practitioners, and was used by the "eclectic physicians" before its virtues came to the knowledge of the profession.

dilated insensible pupils, falling of the lower jaw, loss of power of enunciation, and excessive muscular relaxation are associated with slow, labored breathing, which in some cases is interrupted by violent spells of dyspnoea; consciousness is long unimpaired, but is apt to be lost before death, and in rare cases unconsciousness has been present, even although recovery followed. Of the various symptoms of gelsemium poisoning the most characteristic are the dropping of the jaw and the ocular manifestations, combined with general muscular relaxation. The effects usually begin in half an hour, but sometimes almost immediately. According to Wormley, death has occurred at periods which vary from one to seven and a half hours. Twelve minims of the fluidextract are said to have proved fatal to a boy three years old, and thirty-five drops of a tincture of the bark have caused death in one hour and a half. In several instances a drachm of the fluidextract has, under treatment, been recovered from. M. P. Hatfield has recorded a case in which fifteen grains of a resinoid extract of gelsemium caused the death of a woman in one hour.

The treatment of poisoning by gelsemium should consist in evacuating the stomach, maintaining absolute rest in the horizontal position, keeping up the bodily temperature, if required, by external warmth, and administering spinal and arterial stimulants. We have very little experimental data as to the physiological antidotes to gelsemium. Our general knowledge indicates that morphine, atropine, strychnine, and digitalis given hypodermically should be of service in the treatment of the poisoning, and Courtright (quoted by Wormley) narrates a case in which the hypodermic injection of three grains of morphine, in divided doses, within a few moments was followed by marked improvement and recovery, although the patient had taken between one and two teaspoonfuls of the tincture of gelsemium. The combined injection of atropine and morphine probably affords the best available treatment.

Physiological studies, while by no means complete, have thrown much light upon the action of gelsemium. The muscular weakness which it causes is always associated with a depression of reflex activity, and is the result of a direct paralyzing influence upon the spinal cord, as probably is also the diminution of sensibility, the nerves and muscles not being sensibly affected by the poison. The action upon the circulation is less marked than upon the nervous system, the heart and arterial pressure not being much affected by therapeutic doses. After toxic amounts there is great depression of the circulation, which has been shown by I. Ott to be at least in part due to a direct action upon the heart. The dilatation of the pupil which is present in poisoning with the drug, and which is also produced by its local application to the eye, is probably due to a paralysis of the oculomotor nerve, to which also may be ascribed the palsy of accommodation

and of the external rectus muscle. The diseases in which the medicine has been prescribed are *intermittent, remittent, typhoid, and yellow fevers, inflammation of the lungs and pleura, dysentery, rheumatism, neuralgia, dysmenorrhœa, delirium tremens, trismus nascentium, chorea, hysteria, and epilepsy*. The drug is, however, not applicable to the treatment of low fevers, and is not sufficiently powerful as a cardiac depressant to be relied upon in very sthenic inflammations; its use should be chiefly restricted to spasmodic and neuralgic affections. In *supraorbital neuralgia, dysmenorrhœa, and in odontalgia* it has been especially commended.

There is much testimony as to its antiperiodic properties, and it may be used as an adjuvant to quinine in the treatment of *remittent fever*. James D. McGarghey praises it especially in cases of *intermittent fever*, when the attacks are disposed to return obstinately and irregularly. (*P. M. T.*, March 7, 1874.) It has also been employed with a measure of success in controlling *cardiac palpitations*. The gelsemine of Wormley included gelseminine and was consequently powerful. Until both alkaloids are found in commerce in a state of purity it would be unwise to state the dose of either.

Gelsemium should be administered in the form either of the tincture or of the fluidextract, the dose of the tincture being ten minims (0.6 Cc.), that of the fluidextract two minims (0.12 Cc.); to be repeated, if necessary, every 2, 4, or 6 hours, and gradually increased until the object is obtained, or some obvious effect is produced on the system.

Dose, of gelsemium, one to two grains (0.065 to 0.13 Gm.).

GENTIANA. U. S. (Br.)

GENTIAN

(gên-ti-à-nà)

"The dried rhizome and roots of *Gentiana lutea* Linné (Fam. *Gentianaceæ*)." *U. S.* "The dried rhizome and roots of *Gentiana lutea*, Linn." *Br.*

Gentiana Radix, *Br.*, Gentian Root, Bitter Root, Fel Root; Radix Gentianæ Rubræ (vel Luteæ vel Majoris); Gentiane (Racine), *Fr. Od.*; Racine de Gentiane (de Gentiane jaune), Gentiane jaune, *Fr.*; Radix Gentianæ, *P. G.*; Enzian, Enzianwurzel, Bitterwurz, Rother Enzian, *G.*; Genziana, *It.*; Genciana (Raiz de), *Sp.*

Gentiana lutea, Willd., *Sp. Plant.* i. 1331; Woodv., *Med. Bot.*, p. 273, t. 95; Carson, *Illustr. of Med. Bot.*, ii. 12, pl. 60—*Yellow Gentian* is among the most remarkable of the species which compose this genus, both for its beauty and great comparative size. From its thick, long, branching, perennial root, an erect, round stem rises to the height of three or four feet, bearing opposite, sessile, ovate, acute, five-nerved leaves of a bright-green color, and somewhat glaucous. The lower leaves, which spring from the root,

are narrowed at their base into the form of a petiole. The flowers are large and beautiful, of a yellow color, peduncled, and placed in whorls at the axils of the upper leaves. The calyx is monophyllous, membranous, yellowish, and semi-transparent, splitting when the flower opens, and reflected when it is fully expanded; the corolla is rotate, and deeply* divided into five or six lanceolate, acute segments; the stamens are five or six, and shorter than the corolla. The plant grows among the Apennines, the Alps, the Pyrenees, and in other mountainous or elevated regions of Europe. It is stated by Bourquelot and Hérissé that in order to develop the deep colored fracture preferred by many druggists the root is frequently submitted to fermentation by heaping it up into a mass which becomes heated. Gentian root which has thus been treated is said to yield 27 per cent. less extractive than does that which has been properly dried. Further, even in the best commercial dried root the *sucrose, gentianose* and *gentiopicroin* of the fresh root are present only in extremely small amounts. (*J. P. C.*, 6, 16, 513.)

Several other species possess analogous virtues, and are used for similar purposes. The roots of *G. purpurea* and *G. punctata*, inhabiting the same regions as *G. lutea*, and of *G. pannonica*, growing in Austria, are said to be often mingled with the official, from which they are scarcely distinguishable. The *G. macrophylla* of Pallas is used in Siberia; one indigenous species, *G. Catesbei* (now *G. Elliottii*, Chapm.),¹ growing in the Southern States, formerly had a place in the secondary catalogue of the U. S. Pharmacopœia, and is reputed to be but little inferior to the official species. *G. quinquefolia*, L. (*G. quinqueflora*, Lam.), growing throughout the Northern and Northwestern States, is said to be much used in domestic practice. In Europe the rhizome of the *G. asclepiadea* and *G. lutea* are often admixed with the official rhizome. According to Vogl they can be detected by the abundance of lignified prosenchymatous elements and stone cells, the genuine powder containing scarcely any lignified elements other than large reticulated vessels. (*O. Z.*, 1903, 141.)

Properties.—As found in commerce, gentian is in pieces of various dimensions and shapes, usually of considerable length, consisting some-

times of longitudinal slices, sometimes of the root cut transversely, twisted, wrinkled externally, sometimes marked with close transverse rings of a grayish-brown color on the outside, yellowish or reddish within, and of a soft, spongy texture. It is officially described as occurring "in nearly cylindrical pieces or longitudinal slices, of variable length and from 5 to 35 Mm. thick; externally yellowish-brown, the rhizome annulate, the roots longitudinally wrinkled; fracture short but uneven, the bark rather thick, separated from the somewhat spongy, reddish-yellow or brownish inner portion by a dark brown cambium zone; odor strong, characteristic; taste slightly sweetish, strongly and persistently bitter. The powder is free from starch grains and sclerenchymatic tissues." *U. S.* No distinct pith, liber cells, starch granules, or raphides are found in gentian. (See *P. J.*, 1872, 42.) The odor is feeble, but decided and peculiar. The taste is slightly sweetish and intensely bitter, without being nauseous. The powder is yellowish. Water and alcohol extract the taste and virtues of the root. "Gentian Root should not yield any definite reactions with the tests for starch." *Br.*

Kromayer, in 1862, first obtained the bitter principle of gentian in a state of purity, and gave it the name of *gentiopicroin*, and the formula $C_{20}H_{30}O_{12}$. It is a neutral body, crystallizing in colorless needles, which readily dissolve in water. It is soluble in spirit of wine, but in absolute alcohol only when aided by heat; it does not dissolve in ether. A solution of sodium hydroxide forms with it a yellow solution. Under the influence of diluted acids, gentiopicroin is resolved into glucose and an amorphous yellowish-brown neutral substance named *gentiogenin*. Fresh gentian roots yield about one-tenth per cent. of gentiopicroin. Another constituent is *gentianin* or *gentisin*, $C_{14}H_{10}O_8$. It forms tasteless, yellowish prisms, subliming with partial decomposition at a temperature over 300° C., sparingly soluble in alcohol, and with alkalis yields intensely yellow, crystallizable compounds, easily decomposed by carbon dioxide. Von Kostanecki (*A. J. P.*, 1891, p. 192), by boiling gentisin with hydriodic acid, succeeded in demethylating it, and so obtained *gentisein*, $C_{13}H_9O_8$, which crystallizes with 2H₂O in fine straw-colored needles; these become anhydrous at 100° C. A triacetyl derivative was then formed from this gentisein. Gentisin is therefore the methyl ether of gentisein, and can be written

showed, in 1875, that when *gentianin* was melted with potassium hydroxide it yielded *phloroglucin*, $C_6H_3(OH)_3$, and *dioxybenzoic acid*, $C_6H_3(OH)_2COOH$. The latter was at first called *gentianic* or *gentisinic acid*. Maisch believed that tannin is absent from gentian root, and states that the dark olive-green coloration

¹ *Gentiana Elliottii*, Chapm.—The blue gentian has a perennial, branching, somewhat fleshy root, and a simple, erect, rough stem, rising eight or ten inches in height, and bearing opposite leaves, which are ovate-lanceolate, acute, and rough on their margin. The flowers are of a palish-blue color, crowded, nearly sessile, and axillary or terminal. The divisions of the calyx are linear-lanceolate, and longer than the tube. The corolla is large, ventricose, plaited, and divided at its border into ten segments, of which the five outer are more or less acute, the five inner bifid and fringed. The number of stamens is five, and the two stigmas are seated on the germ. The capsule is oblong, acuminate, with two valves, and a single cell. *G. Elliottii*, Chapm. grows in the grassy swamps from Virginia to Florida, where it flowers from September to December. It was named by Elliott (1817) in honor of Catesby. It may be given in powder in the dose of from fifteen to thirty grains, or in the form of extract, infusion, wine or tincture.

observed when ferric chloride is added to its preparations is due to gentisic acid (A. J. P., 1876). Ville (A. J. P., 1877) and Davies (P. J., 1879) maintain that there is a small quantity of tannin in gentian root. Patch (A. J. P., 1876) found that an alcoholic solution of an ethereal extract of gentian yielded a dark-green coloration with ferric salts, but if the alcoholic solution were diluted with water it yielded no precipitate with gelatin. Subsequently (Proc. A. Ph. A., 1881) he showed that there was a principle associated with the resinous matter in gentian (but which was not isolated in a state of purity) that produced the reactions of a tannin, viz., a greenish-black color with ferric chloride, and precipitated by tartar emetic, cinchonidine sulphate, and gelatin. Louis Magnes found in the root, when perfectly dried at 100° C. (212° F.), 15 per cent. of glucose, and 12 per cent. in the root in its ordinary state. (A. J. P., pp. 333-4.) When gentian is macerated in cold water, it undergoes the vinous fermentation, in consequence of the presence of this saccharine principle. From the fermented infusion a spirituous liquor is obtained by distillation, which, though bitter, and having an unpleasant odor, is said to be relished by the Swiss and Tyrolese. A. Meyer (Ph. Ch., 1882, May) obtained a sweet principle, which he called *gentianose*, $C_{16}H_{26}O_{11}$, by precipitation of the filtered juice with alcohol, treatment with ether, and crystallization from alcohol. It does not reduce Fehling's solution. Infusion of gentian is precipitated by tannic acid and the soluble salts of lead, but is compatible with the salts of iron. Pectin, so frequently found in fleshy roots, exists in gentian. (Bourquelot and Herissey, *Répert. de Pharm.*, 1898.) The yellow coloring matter of the root was investigated by E. V. Howell, who concludes that it is quercitrin.

Uses.—Gentian possesses in a high degree the tonic powers of the simple bitters. It excites the appetite and invigorates digestion. In very large doses, however, it is apt to oppress the stomach, to irritate the bowels, and even to occasion nausea and vomiting. It has been known from the highest antiquity, and is said to have derived its name from Gentius, a king of Illyria. Many of the complex preparations handed down from the Greeks and Arabians contain it among their ingredients; and it enters into most of the stomacheic combinations employed in modern practice. It may be used in all cases of pure debility of the digestive organs, or where a general tonic impression is required. *Dyspepsia*, *atonic gout*, *amenorrhœa*, *hysteria*, *scrofula*, and *intermittent fever* are among the many affections in which it has proved useful, but it is the condition of the stomach and of the system generally, not the name of the disease, which must be taken into consideration in prescribing it, and there is scarcely a complaint in which it can be advantageously given under all circumstances. The porous property of the root causes it to ex-

pand with moisture, and it has been employed as a substitute for sponge tent in the enlargement of strictured passages.

Dose, fifteen to thirty grains (1 to 2 Gm.).

GERANIUM. U. S.

GERANIUM [Cranesbill]

(ge-rā'nī-ŭm)

"The dried rhizome of *Geranium maculatum* Linné (Fam. *Geraniaceæ*)."
U. S.

Cranesbill Root, Spotted or Wild Cranesbill, or Storksbill, Alum Root; Racine de Bec-de-Grue tacheté, Racine de Pied-de-Corneille, Fr.; Fleckstorchschnabel-wurzel, G.

Geranium maculatum, L., *Sp. Pl.* (1753), 681; Willd., *Sp. Plant.* iii. 705; Bigelow, *Am. Med. Bot.*, i. 84; Barton, *Med. Bot.*, i. 149.—This plant has a perennial, horizontal, fleshy rhizome, which is furnished with short fibres, and sends up annually an herbaceous stem, with several radical leaves. The stem is erect, round, dichotomously branched, from one to two feet high, of a grayish-green color, and thickly covered, in common with the petioles and peduncles, with reflexed hairs. The leaves are deeply divided into three, five, or seven lobes, which are variously incised at their extremities, hairy, and of a pale green color, mottled with still paler spots. Those which rise from the root are supported on footstalks eight or ten inches long; those of the stem are opposite, the lower petiolate, the upper nearly sessile, with lanceolate or linear stipules. The flowers are large, and usually of a rose-purple color. The peduncles spring from the forks of the stem, and severally support two flowers upon short pedicels. The calyx is composed of five oblong, ribbed, cuspidate leaves; the petals are five, obovate, and entire; the stamens ten, with oblong, deciduous anthers, the five alternate filaments being longer than the others, and having glands at their base; the ovary is ovate, supporting a straight style as long as the stamens, and surmounted by five stigmas. The fruit consists of five aggregate, one-seeded capsules, attached by a beak to the persistent style, curling up and scattering the seeds when ripe. The plant is indigenous, growing throughout the United States in moist woods, thickets, and hedges, and generally in low grounds. It flowers from May to July. The root should be collected in autumn.

Properties.—Geranium occurs in pieces from one to three inches long, from a quarter to half an inch in thickness, somewhat flattened, contorted, wrinkled, tuberculated, and beset with slender fibres. It is externally of an umber-brown color, internally reddish gray, compact, inodorous, and of an astringent taste, without bitterness or other unpleasant flavor. "Of horizontal growth, cylindraceous, somewhat flattened and rather sharply tuberculated,

2.5 to 10 Cm. long and 3 to 15 Mm. in diameter; longitudinally wrinkled, dark brown; fracture short, light reddish brown or purplish; bark thin; wood indistinct; central pith large; odor slight; taste strongly astringent." *U. S.* Water and alcohol extract the virtues of geranium. According to Edward Staples, it contains tannic and gallic acids, mucilage, red coloring matter, resin, and a crystallizable vegetable principle. (*A. J. P.*, 1829, p. 171.) Tilden found, besides tannic and gallic acids, gum, pectin, sugar, starch, albumen, resin soluble in alcohol, oleoresin soluble in ether only, coloring matter, chlorophyll, lignin, and various salts. (*P. J.*, 1863, p. 22.) Tannic and gallic acids are probably the sole active ingredients. Henry Trimble and J. C. Peacock (*A. J. P.*, 1891, p. 265) collected the plant at periods of the year ranging from January to October, and determined the percentage of tannin as calculated for the perfectly dry drug to vary from 9.72 to 27.85 per cent. They also determined that it belonged to the class of tannins analogous to gallo-tannic acid, yielding pyrogallol on heating. They decomposed the tannin by the action of hydrochloric acid, obtaining gallic acid, glucose, and geranium red as products.

Uses.—Geranium is one of our best indigenuous astringents, and may be employed for all the purposes to which these medicines are applicable. The absence of unpleasant taste and of other offensive qualities renders it peculiarly serviceable in the case of infants and of persons of very delicate stomach. *Diarrhæa, chronic dysentery, cholera infantum* in the later stages, and the various hemorrhages, are the forms of disease in which it is most commonly used and with greatest advantage; but care should be taken, before it is administered, that the condition of the system and of the part affected is such as not to contra-indicate the use of astringents. As an application to *indolent ulcers*, an injection in *gleet* and *leucorrhæa*, and a gargle in *relaxation of the uvula* and *aphthous ulcerations* of the throat, it answers the same purpose as kino, catechu, and other medicines of the same class. It is a popular domestic remedy in various parts of the United States, and is said to be employed by the Indians. It may be given in substance, decoction, tincture, or extract.

Dose, fifteen to thirty grains (1 to 2 Gm.).

Off. Prep.—Fluidextractum Geranii, *U. S.*

GLANDULÆ SUPRARENALES SICCÆ. U. S.

DESICCATED SUPRARENAL GLANDS

(glân'dû-læ sū-prā-rē-nā'les sic'cæ)

"The suprarenal glands of the sheep (*Ovis aries* Linné) or ox (*Bos taurus* Linné), freed from fat, and cleaned, dried, and powdered." *U. S.*

Glandes Surrénales desséchées, *Fr.*; Getrocknete Nebennieren, *G.*

This powder was introduced into the *U. S. Pharm.* (8th Rev.) for the first time.

Properties.—It is officially described as "a light yellowish-brown, amorphous powder, having a slight, characteristic odor; partially soluble in water. One part of Desiccated Suprarenal Glands represents approximately 6 parts of fresh glands, free from fat. Upon incineration it should not yield more than 7 per cent. of ash. If 0.5 Gm. of Desiccated Suprarenal Glands be macerated with 25 Cc. of water for fifteen minutes, and filtered, the filtrate should give an emerald-green color upon the addition of a few drops of ferric chloride T.S. The green color disappears quite rapidly." *U. S.* In no portion of physiology is there at present more uncertainty of knowledge and activity of research than in regard to the functions of the suprarenal bodies. Two theories have been strenuously upheld,—one that these bodies have for their function the destruction of certain poisons, and that the substances found in them have been gathered out from the blood for the purposes of removal; the other that the suprarenal bodies produce a very active substance necessary for the health of the organism.

Whichever of these theories be correct, it is established that the suprarenal bodies do contain in them a substance of remarkable physiological activity. This principle was first isolated in the form of its benzoyl compound by John J. Abel of Johns Hopkins University, and called *epinephrin*. Later it was obtained in the crystalline state by Takamine and by Aldrich, the former giving it the formula $C_{10}H_{15}NO_3$, while the latter found the formula $C_9H_{13}NO_3$. Takamine gave his preparation the name *adrenalin*, and its commercial manufacture was begun under this name. Abel (*A. J. P.*, 1903, p. 309) considered that neither the Takamine nor the Aldrich preparations were pure, and for the pure product, which he calls *epinephrin hydrate*, he gives the formula $C_{10}H_{15}NO_3 + \frac{1}{2}H_2O$. Jowett (*C. D.*, 1904, p. 276), as the result of a study of the subject, declares for the formula $C_9H_{13}NO_3$, proposed by Aldrich.

Uses.—It is probable that the suprarenal glands or so-called capsules have two functions; one the destruction of poisons in the blood and second the secretion of a substance which has a powerfully stimulating effect on the general circulation, acting at the same time upon the heart itself and upon the muscular coats of the arterioles. The intravenous injection of the extract of the glands produces an enormous rise in the arterial pressure, which, however, is extremely transitory, probably on account of the destruction of the active principle in the system. Both Gottlieb and Langlois failed to prolong the action of the extract by ligating the renal arteries. When given hypodermically the action of the glands upon the circulation is very feeble and when administered by the mouth it produces no sensible effect. According to Lewandowsky it acts as a stimulant, not only to the vascular muscle fibres, but to all

the involuntary muscles, including those of the intestines and to the erector pilæ. In the rabbit the repeated injection of the active principle of suprarenal glands has led to pulmonary œdema and extreme atheroma of the arteries.

On account of the feebleness of its influence when given by the mouth the suprarenal extract is of very little practical use as a general stimulant to the circulation, but its active principle or the thoroughly aseptic extract given intravenously may be of service in *shock* and sudden *cardiac collapse* such as sometimes occurs during anæsthesia and under other conditions. The repeated use of the substance would seem, however, interdicted on account of the danger of causing œdema of the lungs.

As a local stimulant to the vessels the extract is an extremely valuable remedy in the treatment of inflammations of the mucous membrane as *conjunctivitis*, *rinitis*, *pharyngitis*, *hay fever* and the like. Owing to its vaso-constrictor effect it has also been found of service in local hemorrhages as *epistaxis*, *hematemesis*, *intestinal bleeding* and *operative hemorrhage*.

Internally it is of value in *Addison's disease*. It has been recommended by Cohen in *asthma*, and by Huchard in *neurasthenia*. The proprietary preparation of the adrenals known as *rachitol*, supposed to be of value in *rickets*, appears to be useless.

Locally, the suprarenal may be used in solutions of the extract in the proportion of 5 to 25 per cent. As these solutions form excellent culture media for bacteria they are not permanent unless an antiseptic is added. The solution of the alkaloid, which is marketed under various trade names in the form of a 1 to 1000 solution, may be used as a hemostatic or in the treatment of congestions and inflammations in a 1 to 10,000 solution. Internally the dried extract is given in doses of five to ten grains (0.3 to 0.6 Gm.).

Dose, five to twenty grains (0.32 to 1.3 Gm.).

GLANDULÆ THYROIDEÆ SICCÆ.

U. S. (Br.)

DESICCATED THYROID GLANDS

(glân'dú-læ thîr-ôid'ê-æ. sic'cæ)

"The thyroid glands of the sheep (*Ovis aries* Linné), freed from fat, and cleaned, dried, and powdered." U. S.

"A powder prepared from the fresh and healthy thyroid gland of the sheep. Remove the external fat and connective tissue from thyroid glands taken from sheep immediately after killing. Cut the glands across, and reject any which contain cysts, are hypertrophied, or otherwise abnormal. Mince finely the healthy glands, and dry at a temperature of 90° to 100° F. (32.2° to 37.8° C.); powder the dried

product; remove all fat from it by treatment with *petroleum spirit*; and again dry the residue." Br.

Thyroideum Siccum, Br.; Dry Thyroid; Getrocknete Schilddrüsen, G.

Desiccated thyroid glands were introduced into the U. S. P. (8th Rev.) for the first time; the British Pharmacopœia introduced this preparation in the 1898 edition (see also *Liquor Thyroidei*). The process for dry thyroid is given above; the objection to its use is that the powder may contain bacteria, or even ptomaines, if great care is not used in its preparation; it is also stated that glycerin does not dissolve all of the thyroiodin which is the principal active constituent, and "Thyroid Solution" cannot be thoroughly representative.

Properties.—Dry thyroid is officially described as "a yellowish, amorphous powder, having a slight, peculiar odor, and containing the active ingredients of the thyroid tissue; partially soluble in water. One part of Desiccated Thyroid Glands represents approximately 5 parts of the fresh glands. Upon incineration it should yield not more than 6 percent. of ash. If 1 Gm. of Desiccated Thyroid Glands be mixed with an equal weight of pure sodium hydroxide and carefully fused in a silver dish, and oxidized by adding potassium nitrate while fusing, until a white mass remains, and if the fused mass be dissolved in a small quantity of water, the solution treated with 2 Gm. of sodium nitrite, acidified with concentrated nitric acid, and then shaken with 5 Cc. of chloroform, a decided pink to violet coloration should be imparted to the latter (presence of *iodine compounds*). A cold extract of Desiccated Thyroid Glands treated with 2 Gm. of sodium nitrite and acidified with strong nitric acid should not give the iodine test on shaking with chloroform." U. S. "A light dull-brown powder, with a very faint meat-like odor and taste, and free from any flavor of putrescence. It is liable to become damp on exposure to the air, and then deteriorates." Br. Many preparations of the thyroid glands are upon the market, most of which are powders or so-called standardized extracts. The active principles have not been isolated in such a state of purity as to admit of accurate description.

In 1895 Baumann (*Zeits. f. Phys. Chemie*, Bd. xxi.) announced the discovery in the thyroid body of *thyroiodin*, and his allegation that it is the active principle of the thyroid gland has been confirmed by E. Roos, Arthur Hennig, Truebel, Ewall, E. Levy, and others, so that its remedial activity seems to be established, although it is probable that there is a second active substance in the gland. *Thyreocantitoxin* of Fränkel (*Aerztl. Central Anzeiger*, 1895) contains no iodine and appears not to be active. Luiffet (*P. J.*, 1900, 440) confirms the results of Baumann that the iodine content of the glands varies in animals, and that the thyroids

of sheep fed on salt marshes are richer in iodine than those grazed on pastures not abnormally saline. The U. S. P. test for iodine content has been criticised, some chemists asserting that desiccated thyroid glands are effective when they do not respond to this test. See also P. J., 1898, 482.

Iodo-globulin, which is believed to be active, is destroyed by boiling in acid or alkaline solutions, but may be extracted by macerating the glands in cold water and evaporating the solution at 100° C. (212° F.). Thyroidiodin exists in small proportion (1 in 333). E. C. C. Stanford has furnished the following process for the mixed powder termed *thyroglandin*. "The thyroid glands, freed from fat and minced, are first macerated in four to five times their weight of cold water, using ice if necessary in summer to keep down the temperature to 50° F., for twenty-four hours, and this maceration is repeated. The solutions are filtered off and evaporated to dryness at a temperature not exceeding 212° F. The extract is powdered, and represents the iodo-globulin and a small proportion of saline matter. The residue from the cold water maceration is boiled for one hour with a 1 per cent. solution of sodium hydroxide (in the proportion of 1 per cent. of sodium hydroxide to the original weight of the glands). The solution is allowed to cool to deposit the fat, and filtered off. This solution is then carefully neutralized with hydrochloric acid and evaporated to dryness at 212° F.; the residue, which contains all the thyroidiodin, is then powdered and mixed with the iodo-globulin obtained in the first process. The resulting powder is thyroglandin." (Y. B. P., 1898, 354.)

Uses.—It has been proved upon the human being by Kocher of Berne, and upon monkeys by Horsley of London, that the removal of the thyroid body is followed by the production of increasing weakness, associated with swelling of the body, enlargement and thickening of the skin, mucoid exudation into the subcellular tissue, and a very extraordinary slowing of all functions,—a condition which progresses until the subject sinks into a state of complete apathy, with subnormal temperature and failure of all vital functions. This congeries of symptoms is the same as that previously described under the name of *myxœdema* by Ord. Both surgical and idiopathic myxœdema have in a large number of cases been treated by the use of the thyroid extract, with such extraordinary results as to leave no doubt but that this extract is a specific in myxœdematous diseases, and is also an extremely valuable remedy in *cretinism*, a condition very closely allied to myxœdema.

In a number of cases the free continuous exhibition of the thyroid gland has been followed by progressive loss of weight, shortness of breath, weak and rapid pulse, and great nervousness, constituting the condition known as *thyroidism*. The loss of weight, which is

very marked, appears to be in part accounted for by an increased destruction of the nitrogenous substances of the body, with a corresponding increase in the output of urea, but in chief part to the result of the destruction of fat. From studies on the lower animals and upon man it is plain that the thyroid gland contains in it some substance which pronouncedly affects nutrition, a fact the recognition of which by the profession has led to the experimental use of the thyroid body in a very large number of conditions connected with disturbed nutrition. It seems well established that the drug is valuable in that form of *goitre* which is indigenous to Switzerland, but is much more likely to do harm than good in *exophthalmic goitre* or *Basedow's disease*. Also, that it is often of great service in the treatment of *obesity*. It has been widely used in various forms of *insanity* and in various diseases of the skin, with, on the whole, not satisfactory results, so that its employment in these affections may be said to be already passing out of vogue. Great advantage, however, is asserted to have followed its use in cases of *keloidal scars* where there has been excessive formation of fibrous tissue.

In all these cases the thyroid preparation acts simply by supplying to the system an organic principle which the thyroid body in the patient has failed to produce in sufficient quantity. The thyroid body is, therefore, in most cases a palliative, so that its continuous administration is necessary, large doses being first given until the evils wrought by the absence of the thyroid gland have been overcome, and smaller doses being afterwards exhibited to maintain the bodily health which has been restored by the larger doses. The raw or slightly boiled thyroid gland may be used to the amount of from a quarter to half of the gland of the sheep daily, but the preparations are perhaps equally efficacious and certainly much better taken by patients. Under the name of *iodothyryn* there is sold commercially a substance claiming to be thyroidiodin with sugar; it is said to be of such strength that one gramme of it contains 0.3 milligramme of iodine and is equivalent to one gramme of the fresh gland. A dose of from one to two grammes a day may be given to an adult. The rule is, in all cases in which the thyroid body is used, to increase the dose until a satisfactory result is obtained or slight evidences of thyroidism appear. In an elaborate series of experiments, R. H. Cunningham believed that he had proved that the symptoms of thyroidism are simply produced by secondary products of decomposition in the thyroid body during the making of these preparations, and may be caused by extracts from almost any kind of animal tissues, and reached other conclusions gainsaying the value of the thyroid body as a therapeutic agent. A discussion of this matter would require too much space to be entered into here. Suffice it at present to state that the clinical and experi-

mental evidences of the value of the thyroid gland in the conditions spoken of seem to us unimpeachable.

Of the dried extract the *dose* is from one to three grains (0.065 to 0.2 Gm.), three times a day, in capsules.

Dose, two to five grains (0.13 to 0.32 Gm.).

GLYCERINUM. U. S., Br.

GLYCERIN GLYCEROL

(glŷ-ċ-ċ-rĭ'nŭm)

"A liquid obtained by the decomposition of vegetable or animal fats, or fixed oils, and containing not less than 95 percent. of absolute Glycerol, a triatomic alcohol [$\text{CH}_2\text{OH}.\text{CHO}.\text{H}.\text{CH}_2\text{OH} = 91.37$]." U. S. "Glycerin, or glycerol, is a trihydric alcohol, $\text{C}_3\text{H}_5(\text{OH})_3$, associated with a small percentage of water; it is obtained by the interaction of alkalies, or of superheated steam, with fats and fixed oils." Br.

Glycerina, U. S. 1870; Glycerine; Glycerine officinale, Fr. Cod.; Glycerinum, P. G.; Glycerin, Glyceriolyhydrat, Oelsüss, Scheelesches Süß, G.; Glycerina, It., Sp.

Litharge, olive oil, and water are boiled together in the 1890 process for making lead plaster; the olein of the oil is decomposed by the lead oxide, according to the following reaction:

by which lead oleate or plaster and free glycerin are obtained. (See *Emplastrum Plumbi*.) It follows, therefore, that the plaster, while still hot and in the liquid state, contained glycerin diffused through it. It was this process that was used for preparing glycerin in the formula of U. S. P. 1850. In accordance with this, when the liquid plaster is mixed with an equal measure of boiling water, and the mixture stirred briskly, a solution of glycerin is obtained, which, after having been decanted, and evaporated to a limited extent, is freed from lead by hydrogen sulphide. The liquid is then filtered to separate lead sulphide, heated to free it from hydrogen sulphide, and finally evaporated to expel the water, which is known to be all removed when the mass ceases to lose weight.

Glycerin was discovered in 1789 by Scheele, by whom it was called the *sweet principle of oils*. It is produced not only during the saponification of the fats and oils by lead oxide in forming lead plaster, but also during the same process when effected by potassium and sodium hydroxides in the manufacture of soap, the alkalies uniting with the fatty acids and setting the glycerin free. Soap-maker's waste is an abundant source of glycerin; but when thus obtained it is apt to have more or less odor, which even percolation through animal charcoal does not always remove. The recovery of glyce-

erin from spent soap lyes is now effected very generally by the Van Ruymbeke process. The lye is settled and drawn off from the sludge, treated with a "persulphate of iron" containing about 50 per cent. of sulphuric acid, which forms a copious precipitate of ferric hydroxide and iron soaps and carries down all other insoluble impurities. After filtration, the lye, which is nearly water-white, is evaporated in vacuo. Some sodium sulphate and sodium chloride crystallize out, after which the glycerin is concentrated and distilled under a high vacuum. The two methods of saponification by which glycerin has been obtained on a large scale are the process of Wilson and Payne, of decomposing the fats by superheated steam and subsequent distillation, and the lime autoclave process of Milly. The process of Richard A. Tilghman of Philadelphia (the patent for which was obtained in 1854, and, after years of litigation, was at last sustained in 1888), consists in subjecting fatty bodies to the action of water at a high temperature under pressure, whereby the fats, which are *glycerides* or *esters* of the fatty acids, are broken up into free glycerin and free fatty acids, the water supplying the elements of hydrogen and oxygen necessary for that change. The reaction is as follows for the case of a fat like stearin:

(See A. J. P., March, 1855, p. 121.) Through a distillatory apparatus containing palm oil, heated steam between 550° and 600° F. is passed. The oil is decomposed into free acids and glycerin, which, together with water, distil over, and, condensing in the receiver, separate into two layers, the lower of which is glycerin. If this, as first procured, contains too much water, it must be concentrated; if discolored, it must be redistilled with steam. (P. J., 1861, p. 350.) Ordinary impure glycerin may be purified by distillation with steam under pressure. Though, when distilled alone, it is partially decomposed, giving off pungent vapors of *acrolein*, yet in a current of superheated steam it passes over unchanged at temperatures between 204.4° and 260° C. (400° and 500° F.). Very pure glycerin is now produced in this country in immense quantities. The United States also imports considerable quantities of glycerin, the amounts for the last three years having been—for 1902, 28,576,400 lbs., valued at \$2,358,325; 1903, 35,295,575 lbs., valued at \$2,937,802; and for 1904, 31,078,455 lbs., valued at \$2,583,270.

Properties.—Glycerin is "a clear, colorless liquid, of a thick, syrupy consistence, smooth to the touch, odorless, sweet to the taste, and producing a sensation of warmth upon the mouth and lips; when exposed to the air, it absorbs moisture. Specific gravity: not less than 1.246 at 25° C. (77° F.). Soluble in all proportions in water and alcohol; also soluble in a mixture of 3 parts of alcohol and 1 part of ether, but insoluble in ether, chlo-

reform, carbon disulphide, petroleum benzin, benzene, and fixed and volatile oils. Glycerin is slowly volatilized from weak aqueous solutions, at or above 100° C. (212° F.), with the vapor of water. At boiling temperatures 70 percent. to 100 percent. Glycerin rapidly volatilizes; 95 percent. Glycerin boils at 165° C. (329° F.); anhydrous Glycerin boils at 290° C. (554° F.) without decomposition; under continued heat it is finally entirely decomposed and dissipated. An aqueous solution of Glycerin is neutral to litmus paper. If a fused bead of borax, on a loop of platinum wire, be moistened with Glycerin, and then held in the edge of a non-luminous flame, the latter will be transiently tinted a vivid green." *U. S.*

as a means of concentrating and purifying glycerin. According to G. F. Wilson, glycerin, when of the density 1.24, contains 94 per cent. of anhydrous glycerin; when of the density 1.26, 98 per cent. A table by Wilhelm Lenz (*Zeit. An. Chem.*, 1880), showing the percentage of absolute glycerin in mixtures of glycerin and water, which was obtained by a quantitative determination of the carbon in the various dilutions by ultimate analysis, will be found in the *U. S. D.*, 15th ed., p. 712. The table below by W. W. J. Nicol of England, has been constructed after careful determinations, aided by A. B. Lyons's data on expansion of glycerin solutions. (*Ph. Era*, 1888.)

Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.	Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.	Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.	Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.

In properties, glycerin is intermediate between water and the oils. When exposed to the air it gradually absorbs moisture. As already stated, though decomposed by a high heat in its unmixed state, yet with water under pressure it is volatilizable unchanged at a temperature between 204.4° and 260° C. (400° and 500° F.). Cooled down rapidly, it only becomes more viscid, without congealing, even when a temperature of -40° C. is attained; but, if kept for some time at a temperature of about 0° C. (32° F.), it gradually forms hard but deliquescent crystals, which melt only at about 22° C. (71.6° F.).¹ This fact is now utilized

Glycerin possesses extensive powers as a solvent, and is an excellent excipient for many medicinal substances. It dissolves bromine and iodine, sulphur iodide, potassium and sodium chlorides, the fixed alkalies, some of the alkaline earths, lime, for example, for which it increases the solvent powers of water (*J. P. C.*, Juin, 1874), and a large number of neutral salts. It also dissolves the vegetable acids, particularly tannic acid. It is a good solvent of pepsin, and is used for the extraction of this principle from the mucus of the stomach. Two parts and a half of glycerin dissolve one of sugar, and three and a half parts, one of gum. When starch paste and glycerin are heated together, a turbid liquid is formed, which deposits on cooling, the supernatant liquid holding starch in solution. (*J. P. C.*, Nov. 1868, pp. 361-2.) J. S. Blockley of London, has ascertained that certain glucosides are far more soluble in glycerin than in water. Thus, salicin dissolves in eight parts of cold glycerin, and santonin in eighteen parts when boiling. The latter solution, when of half this strength, forms on cooling an almost solid mass. It is not always a good solvent for alkaloids

¹ Wm. Crookes gives an account, in the *Chem. News*, of Jan. 18, 1867, of 5 tons of glycerin imported into London from Germany in casks of 8 cwt. each, which, though when it left the Continent was in its ordinary state of a viscid liquid, was found, on reaching London, to have become solidified into a mass of very hard, brilliant crystals. The same result has been noticed in Vienna, in a mass of glycerin which had been in an iron tank more than a year. (*Chem. News*, April 5, 1867.) The crystalline mass noticed by Crookes yielded pure glycerin when melted. Frozen glycerin has been examined by Wallace Procter and Henry Trimble (*A. J. P.*, 1885, p. 273): the crystals had the sp. gr. 1.2618, and the portion which had not been solidified had the sp. gr. 1.235.

or their salts, and will sometimes precipitate the latter even from their aqueous or acidulated solutions. Glycerin, next to alcohol, is the best solvent of iodine. Iodine and potassium iodide, when dissolved in it, form *iodized glycerin*, the medicinal applications of which are given under iodine. (See *Iodum*.)¹ It combines with potassa and baryta, and also with sulphuric acid. Glycerin does not evaporate when exposed to the air, nor can it be distilled without decomposition, unless in the presence of water or steam. When decomposed by heat, it emits extremely irritating vapors of acrolein. At a full red heat it takes fire, and burns with a blue flame. In consequence of the high temperature required for its volatilization, it has been proposed to use it for an evaporating bath, in which a heat beyond that of boiling water is required. Glycerin is antiseptic, and has been recommended by Warrington and Demarquay to preserve alimentary substances and objects of natural history, and to inject bodies for dissection. According to W. Frazer, it does not answer for preserving pathological preparations, as they are completely softened by its action. Berthelot of Paris, succeeded in combining glycerin with a number of acids, both mineral and organic, forming three distinct series of neutral compounds. Among others, he has united it with the fatty acids, producing, by synthesis, the organic fatty substances stearin, palmitin, olein, etc. Glycerin has been formed artificially from tribromallyl, by Wurtz, and from trichlorhydrin, by Friedel and Silva. Synthesis is, however, not practicable on a large scale, no method having yet been discovered to compete successfully with its preparation from natural fats. By Pasteur it was ascertained to be one of the products of the vinous fermentation. Glycerin is a triatomic alcohol, being a compound of the triad radical (C_3H_5) with 3(OH) groups. In the natural fats, the three H atoms of these OH groups are replaced by fatty acid radicals like stearyl, $C_{15}H_{35}O$, palmityl, $C_{16}H_{33}O$, and oleyl, $C_{18}H_{35}O$. The natural fats are, therefore, compounds of an alcohol radical with an organic acid, and are true esters, which are known as *glycerides*.

The solvent and preservative properties as well as agreeable taste and permanent consistence of glycerin render it very useful as a menstruum in pharmacy, and a class of prepa-

arations consisting of medicinal substances dissolved in it has come into extensive use. The British Pharmacopœia has adopted such a class, under the name of *Glycerina*, or *glycerines*. This title "glycerines" is not now available because the termination "ine" is reserved for alkaloids, while the term *glyceroles*, adopted from the French, is objectionable, as the termination "ole" has been used to designate certain proximate principles; but the U. S. Pharmacopœia title, *Glycerita*, or *glycerites*, is satisfactory.

Impurities and Tests.—Glycerin is occasionally deficient in density and consistency. According to Dapiaz, it is sometimes perfectly colorless from being bleached by chlorine, when it is apt to contain calcium chloride, as well as free chlorine. The latter may be detected by rendering the suspected sample slightly blue by a few drops of an acid solution of indigo in sulphuric acid, when, if free chlorine be present the blue color will disappear. Starch paste containing a little potassium iodide is a better test, however; if a blue color appears when this is added to glycerin, free chlorine is indicated.

The U. S. P. (8th Rev.) furnishes the following tests: "Five Cc. of Glycerin, heated to boiling in an open porcelain or platinum dish, and then gently ignited, should vaporize, burn, and leave not more than a dark stain, which on stronger heating should disappear entirely (absence of *mineral impurities*). If 5 Cc. of Glycerin be mixed with 50 Cc. of water and 10 drops of hydrochloric acid in a small flask, and heated for half an hour on a water-bath, then 10 Cc. of the hot liquid, mixed with 2 Cc. of sodium hydroxide T.S. and 1 Cc. of alkaline cupric tartrate V.S., should show no yellowish-red cloudiness or precipitate within six hours (absence of *sugars*). If 5 Cc. of Glycerin be mixed with an equal volume of concentrated sulphuric acid in a test-tube, the liquid should acquire, on standing for one hour, a color not darker than yellow (absence of *readily carbonizable impurities*). If 5 Cc. of Glycerin be mixed with the same volume of a mixture of equal parts of alcohol and diluted sulphuric acid, and gently heated, a fruity odor should not be recognizable (absence of *butyric acid*). No color, cloudiness, or precipitate should appear when separate portions of its aqueous solution (1 in 10) are treated with barium

¹ The following table, by Klever, gives a general view of the solvent powers of glycerin,—100 parts of glycerin dissolving the annexed quantities of substances:

PARTS.		PARTS.		PARTS.		PARTS.	
Acidum arsenicum	.20	Brucina	2.25	Morphina	0.45	Sodii bicarbonas	8

(Neues Jahrb. für Pharm., 1869, Mai u. Juni, 315.)

chloride T.S. (*sulphuric acid*), calcium chloride T.S. (*oxalic acid*), ammonium oxalate T.S. (*calcium salts*), silver nitrate T.S. (*chlorides*), or silver ammonium nitrate T.S. (*acrolein*); in the last-mentioned case, the test-tube, loosely stoppered to protect it from impurities, should be allowed to stand, protected from light, for at least five minutes. The aqueous solution (1 in 20), when acidified with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Five Cc. of the aqueous solution (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (See PART III, Test No. 17).¹ U. S. The Br. Pharm. furnishes the following tests: "Sp. gr. 1.260. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, calcium, potassium, sodium, ammonium, chlorides, or sulphates; and no red precipitate with excess of *solution of potassio-cupric tartrate* on boiling, even when previously acidified and boiled (absence of grape and cane sugars). It should undergo no darkening in color at ordinary temperatures when mixed with an equal volume of *solution of ammonia* and a few drops of *solution of silver nitrate*; and when shaken with an equal volume of *sulphuric acid*, the mixture being kept cool, no coloration, or only a very slight straw coloration, should result (absence of foreign organic matter). When gently heated with a mixture, in equal volumes, of *alcohol* (90 per cent.) and *diluted sulphuric acid*, a fruity odor should not be produced (absence of butyric acid). 2 cubic centimetres diluted with 5 cubic centimetres of a mixture of 1 part of *hydrochloric acid* and 7 parts of *water*, 1 gramme of pure *zinc* being added, and the whole placed in a long test-tube, the mouth of which is covered by a piece of filter-paper moistened with a drop or two of *test-solution of mercuric chloride* and dried, should not afford a yellow stain on the paper even after 15 minutes (limit of arsenium). When heated in an open capsule it yields acid vapors; and is finally dissipated, leaving no ash (absence of fixed mineral matter)." Br.

Arsenic has been shown to exist in small quantities as an impurity in some glycerins; its presence may be suspected whenever sulphuric acid (made from pyrites) has been used in the manufacture of the glycerin, as in the Wilson and Payne process for the decomposition of the fats (see page 586). Lime may be detected by ammonium oxalate; lead, by ammonium sulphide, and sulphuric acid, by a soluble salt of barium. Diluted, and boiled with a solution of potassium hydroxide, it is not altered in color, showing the absence of glucose. Trommer's test is probably more effectual. The presence of even a small proportion of sugar is shown by the following test: Dilute the glycerin with an equal volume of water and introduce 2 Cc. of the mixture into a test tube; pour carefully down the side of the test tube 2 Cc. of a reagent made by dissolving 0.010 Gm. of morphine sul-

phate in 5 Cc. of sulphuric acid (U. S. P.) and adding 1 drop of tincture of ferric chloride (freshly prepared). If sugar is present a band of color will appear at the plane of contact of the two fluids, violet-blue below, orange-yellow above; sulphuric acid alone will produce a yellow to brown zone. (A. B. Lyons, *Proc. A. Ph. A.*, 1905, 331.) According to Hager, sugar or dextrin may be detected in the following manner. Dilute the glycerin with water, add ammonium molybdate and some drops of nitric acid, and boil. If these impurities are present, a blue color is produced; if not, it remains colorless. (*Ibid.*, May, 1869.) Among the most injurious impurities of glycerin are thought to be oxalic and formic acids, the latter of which, being especially irritating to the skin, unfits glycerin for some of the purposes for which it is most employed. The oxalic acid is said to result from the action of sulphuric acid employed in purifying glycerin; the formic, from the reaction between glycerin and oxalic acid. They may be detected by the U. S. P. tests. Henry Bower of Philadelphia, who manufactured very pure glycerin, claimed that silver nitrate is the most reliable test. Glycerin which shows no reaction with this salt he considers suitable for all uses. (A. J. P., 1868.) See improved U. S. P. test above. For a method of extracting glycerin from mixtures containing sugar and glucose, see a paper by Prescott, *N. R.*, 1878. For methods of determining glycerin in mixtures or its detection in wines, etc., see *Chem. News*, 1882; *A. J. P.*, 1882; *S. W. P.*, 1881; *Chem. News*, 1886; *Am. Drug.*, 1886.¹

Uses.—The uses of glycerin as a vehicle for other medicines have been already given. When given internally, it is laxative, and it has also been suggested as a substitute for cod liver oil in *phthisis*, etc. R. P. Cotton, however, has tried it in the Consumption Hospital at Brompton, and shown that it has generally but little influence, and that as a remedial agent it will bear no comparison with cod liver oil. When injected directly into the blood, glycerin produces in the lower animals violent nervous symptoms and death, but this action is probably due to the mechanical alteration of the viscosity of the vital fluid. All our physiological evidence goes to show that glycerin has, unless in very immoderate quantities, no distinct physiological or therapeutic properties other than those of a feeble laxative. It has recently been extensively employed in habitual constipation in the form of suppositories. (See *Suppositoria Glycerini*.) Although at various times much lauded in tuberculous diseases and in *diabetes*, it has entirely failed to gain the confidence of the profession, and is now very rarely employed.

¹ *Glycero-alcohol*, a valuable solvent made by mixing glycerin, 333; distilled water, 146; and alcohol sufficient to measure 1000 parts. Its specific gravity is about 1; it is a good solvent for alkaloids, keeps indefinitely, and does not evaporate readily.

Glycerin is extensively used *externally* as a softening, emollient application in various conditions of the skin. Its affinity for water is such that it sometimes acts as an irritant upon the mucous membrane, unless diluted. It appears to have been first employed externally in 1846, by Thomas De la Rue of London. Added to poultices, in a proportion varying from one-fourth to one-sixteenth, it has the effect of keeping them soft for a long time. To collodion it gives a valuable plasticity. Incorporated in very small proportion with extracts and pills, it keeps them soft and free from mouldiness. In cases of *deafness*, from deficiency, accumulation, or hardness of the cerumen, and attended with dryness of the meatus, glycerin is an excellent remedy, introduced into the canal by means of raw cotton saturated with it. Glycerin may be used in the form of an ointment,¹ and is also used in the menstruum of official extracts, fluidextracts, glycerites, infusions, syrups, tinctures, etc., and in making pills.

Off. Prep.—Cataplasma Kaolini, *U. S.*; Gelatinum Glycerinatum, *U. S.*; Suppositoria Glycerini, *U. S.*, *Br.*

GLYCERINUM ALUMINIS. *Br.*

GLYCERIN OF ALUM

(glŷc-ē-rī'nūm a-lū'mj-nīs)

Glycéré d'Alun, *Fr.*; Alaun-Glycerit, *G.*

"Alum, in powder, 1 ounce (Imperial) or 20 grammes; Distilled Water, 3 fl. drachms (Imp. meas.) or 7.5 cubic centimetres; Glycerin, sufficient to produce 6 fl. ounces (Imp. meas.) or 120 cubic centimetres. Triturate until solution is effected, warming slightly if necessary; set aside; pour off the clear liquid from any deposited matter that may be present." *Br.*

This has the astringency of the glycerite of tannin without the tendency to soil the linen or blacken in contact with iron, but is much more irritating.

GLYCERINUM BORACIS. *Br.*

GLYCERIN OF BORAX

(glŷc-ē-rī'nūm bō-rā'cīs)

Glycéré de Borax, *Fr.*; Borax-Glycerit, *G.*

"Borax, 1 ounce (Imperial) or 20 grammes; Glycerin, 6 fl. ounces (Imp. meas.) or 120 cubic centimetres. Triturate the Borax with the Glycerin until solution is effected." *Br.*

¹ Ecky's glycerin ointment is made as follows. Take of spermaceti half an ounce; white wax a drachm; oil of almonds two fluidounces; glycerin a fluidounce. Melt the spermaceti and wax with the oil of almonds by a moderate heat. Then, having poured the melted liquid into a Wedgwood mortar, add the glycerin, and rub until the ingredients are thoroughly mixed and cool. This ointment may be used with advantage in chaps and excoriations.

The *Glyceritum Sodii Boratis* of *U. S. P.* 1870 was of the strength of one troyounce to four fluidounces. Otherwise it did not differ from the British preparation.

The demulcent properties and sweet taste of this preparation render it a useful and convenient method of applying borax to the infantile thrush and other forms of sore mouth in children. It has been highly commended in *erysipelas* by D. M. Salazar of Madrid. The part should be freely painted with it and then covered with raw cotton. (*N. Y. M. R.*, viii. 311.)

GLYCERINUM PEPSINI. *Br.*

GLYCERIN OF PEPSIN

(glŷc-ē-rī'nūm pēp-sī'nī)

Glycéré de Pepsine, *Fr.*; Pepsin-Glycerit, *G.*

"Pepsin, 800 grains (Imperial) or 80 grammes; Hydrochloric Acid, 110 minims (Imp. meas.) or 10 cubic centimetres; Glycerin, 12 fl. ounces (Imp. meas.) or 525 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Hydrochloric Acid, Glycerin, and six fluid ounces (Imp. meas.) or two hundred and sixty cubic centimetres of the Distilled Water; then add the Pepsin; after one week, pour off the clear liquid, or filter; add sufficient Distilled Water to produce one pint (Imp. meas.) or eight hundred and seventy-five cubic centimetres. 1 fluidrachm of this preparation represents 5 grains of Pepsin." *Br.*

"This preparation is apparently identical with the glycerite of pepsin of the National Formulary, but the pepsin of the British Pharmacopoeia is supposed to be five times as strong as that of the *N. F.*"

Dose, one fluidrachm (3.75 Cc.), equivalent to five grains of pepsin.

GLYCERINUM PLUMBI SUBACETATIS. *Br.*

GLYCERIN OF SUBACETATE OF LEAD

(glŷc-ē-rī'nūm plūm'bī sūb-āc-ē-tā'tis)

Glycéré de Sousacétate de Plomb, *Fr.*; Bleessig-glycerit, *G.*

"Lead Acetate, 5 ounces (Imperial) or 100 grammes; Lead Oxide, in powder, 3½ ounces (Imp.) or 70 grammes; Glycerin, 1 pint (Imp. meas.) or 400 cubic centimetres; Distilled Water, 12 fl. ounces (Imp. meas.) or 240 cubic centimetres. Mix; boil for a quarter of an hour; filter; evaporate at a temperature not exceeding 222° F. (105.5° C.) until the product weighs thirty-two and three-quarters ounces (Imp.) or six hundred and fifty-five grammes, and has a specific gravity of 1.48." *Br.*

This glycerite originated with Balmanno Squire of London, but the process made official is that recommended by R. W. Parker.

(See *A. J. P.*, 1886, 296.) It is a powerful sedative astringent, and may be employed as a local application in external inflammations.

Off. Prep.—Unguentum Glycerini Plumbi Subacetatis, *Br.*

GLYCERINUM TRAGACANTHÆ. *Br.*

GLYCERIN OF TRAGACANTH

(glŷc-ē-rī'nūm trāg-a-cān'thæ)

Glycéré de Gomme Adragante, *Fr.*; Traganth-Glycerit, *G.*

"Tragacanth, in powder, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Glycerin, $1\frac{1}{2}$ fl. ounces (Imp. meas.) or 30 cubic centimetres; Distilled Water, $\frac{1}{2}$ fl. ounce (Imp. meas.) or 10 cubic centimetres. Mix the Glycerin with the Tragacanth; add the Distilled Water; triturate until a homogeneous paste is produced." *Br.*

This preparation has been introduced into the British Pharmacopœia mainly to serve as an excipient for pills.

GLYCERITA.

GLYCERITES

(glŷc-ē-rī'tā)

Glycerina, Br.: Glycerines; Glycerata, Glycerolata, Glycerols; Glycérés, *Fr. Cod.*; Glycérats, Glycérols, *Fr.*; Glycerit, Glycerolat, *G.*

These are solutions of medicinal substances in glycerin. In the thirteenth edition of the Dispensatory various reasons were adduced for preferring the name glycerates for these preparations, but, as the revisers of the U. S. Pharmacopœia have adopted that of glycerites, these reasons are omitted. The U. S. name is certainly much better than the British name glycerin (*Glycerinum*) for this does not distinguish a class of preparations from the solvent used in making them. (See preceding articles.)

Glycerin has valuable properties as a solvent and vehicle for medicinal substances. Such are its not unpleasant taste and bland character, its wide range of solvent power, which adapts it sometimes as a menstruum where neither water nor alcohol could be advantageously used, and enables it to retain in solution otherwise insoluble substances so frequently found in infusions and decoctions, and its preservative influence, which often protects against oxidation, and, by a destructive agency upon all of the lowest forms of vegetable and animal life, prevents the various fermentative processes so destructive to organic bodies. Another important property, as a vehicle for external remedies, is the permanence of its liquid character, so that it does not, like water and alcohol, dry up when applied to the skin, resembling in this respect, as well as in its demulcent quality, the fixed oils, without their tendency to rancidity. Hence it has of late come into extensive use in the preparation of medicinal solu-

tions, which under the name of *Glycérés* found admission into the French Codex of 1866, and are now recognized by both the United States and British Pharmacopœias.¹

GLYCERITUM ACIDI TANNICI.

U. S. (*Br.*)

GLYCERITE OF TANNIC ACID

(glŷc-ē-rī'tūm āc'i-dī tăn'hī-cī)

Glycerinum Acidi Tannici, Br.; Glycerin of Tannic Acid (of Tannin); Glycéré de Tannin, *Fr. Cod.*; Glycérole de Tannin, Glycérine tannique, *Fr.*; Tannin-Glycerit, Tannin-Glycerol, *G.*

* "Tannic Acid, twenty grammes [or 309 grains]; Glycerin, eighty grammes [or 2 ounces av., 360 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Triturate the Tannic Acid with the Glycerin to a smooth paste, transfer this to a porcelain dish, avoiding contact with metallic utensils, and apply the heat of a water-bath, until the Tannic Acid is completely dissolved. Then transfer the solution to a bottle." *U. S.*

"Tannic Acid, 1 ounce (Imperial) or 20 grammes; Glycerin, sufficient to produce 5 fl. ounces (Imp. meas.) or 100 cubic centimetres. Triturate the Tannic Acid with the Glycerin until solution is effected." *Br.*

The U. S. preparation is a 20 per cent. solution by weight; the strength of the British preparation is somewhat weaker, being a 20 per cent. solution by measure. H. F. Meier found that the greenish scum usually seen on the surface of the preparation is chlorophyll from the tannin.

This preparation may be used, both internally and externally, for most of the purposes to which tannic acid is applied. On the whole, it is the most useful preparation of tannic acid for external use; as circumstances require it the official strength may be altered by direction of the physician; a very concentrated solution, two parts of glycerin to one of tannin, may be made by the aid of a moderate heat. This applied daily to nipples,

¹ *Glyceritum Picis Liquidæ*, U. S. 1870. *Glycerite of Tar*.—"Take of Tar a troyounce; Carbonate of Magnesium, in powder, two troyounces; Glycerin four fluidounces; Alcohol two fluidounces; Water ten fluidounces. Having mixed the Glycerin, Alcohol, and Water, rub the Tar in a mortar first with the Carbonate of Magnesium, and then with six fluidounces of the mixed liquids gradually added, and strain with expression. Rub the residue in like manner with half the remaining liquid, and strain as before. Repeat the process again with the remaining liquid. Put the residue into a percolator, add gradually the expressed liquids previously mixed, and afterwards a sufficient quantity of water to make the liquid which passes measure a pint." *U. S.* 1870.

This is a very excellent preparation of tar, which may be used either externally or internally. The formula is essentially the same as that proposed by J. B. Moore, although employing one-third less of the magnesium salt (*A. J. P.*, 1869, p. 115). As first made it is of a reddish-brown color; after a time it is apt to deposit a dark sediment, which should be separated by filtration. An ounce of it represents half a fluidrachm of tar. The dose is from a drachm to a half-ounce (3.75 to 15 Cc.).

during the later months of pregnancy, will usually prevent the occurrence of sore nipples during suckling.

Dose, from ten to forty minims (0.6 to 2.5 Cc.). (See *Acidum Tannicum*.)

GLYCERITUM AMYLI. U. S. (Br.)

GLYCERITE OF STARCH

(glŷc-ē-rī'tūm ām'y-lī)

Glycerinum Amyli, Br.; Glycerin of Starch, Glyc-
amyl, Plasma; Glycéré d'Amidon, Fr. *Ord.*; Glyc-
érate simple (d'Amidon), Fr.; Unguentum Glycerini,
P. G.; Glycerinsalbe, Stärke-Glycerit, G.; Glicerolato
di amido, It.; Glicerolado de almidon, Sp.

* "Starch, *ten grammes* [or 154 grains]; Water, *ten cubic centimeters* [or 162 minims]; Glycerin, *eighty grammes* [or 2 ounces av., 360 grains]. Triturate the Starch with the Water, until a homogeneous mixture is produced. Then gradually add this to the Glycerin, contained in a porcelain dish, and heated to about 140° C. (284° F.). Continue the heat, with constant stirring, keeping it below 144° C. (291.2° F.), until a translucent jelly is formed. Transfer the product to suitable vessels, provided with well-fitting covers." U. S.

"Starch, 1 ounce (Imperial) or 20 grammes; Glycerin, 6½ fl. ounces (Imp. meas.) or 130 cubic centimetres; Distilled Water, 1½ fl. ounces (Imp. meas.) or 30 cubic centimetres. Mix; heat them together, stirring constantly, until a translucent jelly is formed." Br.

Of these preparations it is only necessary to say that, with the exception of an inconsiderable difference in the proportions, they are the same as that brought into notice in 1858 by G. F. Schacht under the name of *plasma*, as a substitute for ointments, the emollient and demulcent properties of which they possess, without their inconvenience, whether used simply, or as a vehicle for other substances to be employed locally. Schacht prepared plasma by mixing 70 grains of starch in powder, and a fluidounce of glycerin, heating to 240° F. until the union is effected, and stirring constantly. The stirring should be continued moderately, during the cooling, to secure a proper consistence. As the plasma is liable to absorb moisture, it should be kept in well closed vessels. (P. J., Oct. 1866, 210.) J. H. Pearson (P. J., 1897, 201) recommends the addition of one grain of powdered tragacanth to the ounce of finished product, to prevent the separation of the glycerin and water from the mass, on standing.

GLYCERITUM BOROGLYCERINI.

U. S. (Br.)

GLYCERITE OF BOROGLYCERIN

[Solution of Boroglyceride]

(glŷc-ē-rī'tūm bō-ro-glŷc-ē-rī'nī)

Glycerinum Acidi Borici, Br.; Glycerin of Boric Acid; Glycerite of Glyceryl Borate; Glycéré de boroglycéride, Fr.; Boroglyceridlösung, G.

* "Boric Acid, in fine powder, *three hundred and ten grammes* [or 10 ounces av., 409 grains]; Glycerin, a *sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Heat *four hundred and sixty grammes* [or 16 ounces av., 99 grains] of Glycerin, in a tared porcelain dish, to a temperature not exceeding 150° C. (302° F.), and add the Boric Acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface. When the mixture has been reduced to the weight of *five hundred grammes* [or 17 ounces av., 279 grains], add to it *five hundred grammes* [or 17 ounces av., 279 grains] of Glycerin, mix thoroughly, and transfer it to suitable vessels." U. S.

"Boric Acid, in fine powder, 6 ounces (Imperial) or 300 grammes; Glycerin, a *sufficient quantity*. Heat *nine ounces* (Imp.) or four hundred and fifty grammes of Glycerin, in a weighed porcelain dish, to a temperature not exceeding 302° F. (150° C.), and add the Boric Acid in portions, constantly stirring. When all is dissolved maintain the temperature of the liquid, frequently stirring and breaking up the film which forms on the surface, until the mixture has been reduced to the weight of *ten ounces* [Imp.] or five hundred grammes; then add *ten ounces* (Imp.) or five hundred grammes of Glycerin; mix thoroughly. The product should weigh *twenty ounces* (Imp.) or one thousand grammes." Br.

This solution was first introduced into the U. S. P. 1890 from the National Formulary. It is a thick, sweet, viscid, colorless liquid, and has the advantage of offering the antiseptic, boric acid, in a very soluble form. It may be made more rapidly than by the above process if one ounce av. of boroglyceride be dissolved in one ounce av. of glycerin with the aid of a gentle heat. (See *Boroglyceride*, PART II.)

GLYCERITUM FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U. S.

GLYCERITE OF THE PHOSPHATES OF IRON, QUININE AND STRYCHNINE

(glŷc-ē-rī'tūm fēr'ri quī-nī'næ ēt
strŷch-nī'næ phōs-phā'tūm)

Glycéré des Phosphates de Fer, de Quinine et de Strychnine, Fr.; Eisen-, Chinin- und Strychnin-phosphat-Glycerit, G.

* "Soluble Ferric Phosphate, *eighty grammes* [or 2 ounces av., 360 grains]; Quinine, *one hundred and four grammes* [or 3 ounces av., 293 grains]; Strychnine, *eight-tenths of a gramme* [or 12½ grains]; Phosphoric Acid, *two hundred cubic centimeters* [or 6 fluid-ounces, 366 minims]; Glycerin, *five hundred cubic centimeters* [or 16 fluidounces, 435 minims]; Water, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluid-ounces, 6½ fluidrachms]. Heat the Soluble

Ferrie Phosphate with two hundred cubic centimeters [or 6 fluidounces, 366 minims] of Water, in a porcelain dish, at a temperature not exceeding 70° C. (158° F.), until it is dissolved. Then add the Phosphoric Acid with the Strychnine and Quinine and sufficient Water to make the product measure five hundred cubic centimeters [or 16 fluidounces, 435 minims] and stir until solution is effected. Mix the solution with the Glycerin, and filter if necessary." *U. S.*

This glycerite was made official in the *U. S. P.* (8th Rev.) for the first time. It is intended solely for use in making the syrup of the phosphates of iron, quinine and strychnine by diluting 1 volume of the glycerite with 3 volumes of syrup.

Dose, fifteen minims (0.9 Cc.).

Off. Prep.—Syrupus Ferri, Quininae et Strychninae Phosphatum, *U. S.*

GLYCERITUM HYDRASTIS. U. S.

GLYCERITE OF HYDRASTIS

(glŷċ-e-rĭ'tŭm hŷ-drās'tis)

Glycéré d'Hydrastis du Canada, *Fr.*; Gelbwurzel-Glycerit, *G.*

* "Hydrastis, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, five hundred cubic centimeters [or 16 fluidounces, 435 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the Hydrastis with three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Hydrastis is practically exhausted. Remove nearly all of the Alcohol, by distillation or evaporation, pour the thick concentrated liquid into five hundred cubic centimeters [or 16 fluidounces, 435 minims] of ice-cold Water, and set it aside, in a cold place, for twenty-four hours. Then filter, pass enough cold Water through the filter to make the filtrate measure five hundred cubic centimeters [or 16 fluidounces, 435 minims], add the Glycerin, and mix thoroughly." *U. S.*

This preparation was transferred to the *U. S. P.* 1890 from the National Formulary. It is intended to take the place of the various preparations which are in vogue and which go under the names of *Fluid Hydrastis*, *Colorless Hydrastis*, etc.¹ The process for this glycerite has been improved by adopting J. U. Lloyd's

suggestion to concentrate the alcoholic tincture by distillation or evaporation and pouring the thick liquid into ice-cold water, for the purpose of separating the oily and resinous matter which is useless. F. A. Sieker found that glycerite of hydrastis as made by the former *U. S.* process varies greatly in strength. (See *Proc. A. Ph. A.*, 1893, 691; also *Ph. Rund.*, 1895, 236, and *Proc. A. Ph. A.*, 1894, 668.) Its medicinal properties are those of hydrastis.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

GLYCERITUM PHENOLIS. U. S. (Br.)

GLYCERITE OF PHENOL [Glyceritum Acidi Carbolici, *Pharm.* 1890, Glycerite of Carbolic Acid]

(glŷċ-e-rĭ'tŭm phen-ô'lis)

Glycerinum Acidi Carbolici, *Br.*; Glycerin of Phenol; Glycérôle d'Acide Phénique, Glycéré de Phenol, Glycérine Phénique, *Fr.*; Phenol-Glycerit, *G.*; Glycerina con acido fenico, *Sp.*

* "Liquefied Phenol, twenty cubic centimeters [or 325 minims]; Glycerin, eighty cubic centimeters [or 2 fluidounces, 338 minims], to make one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Add the Liquefied Phenol to the Glycerin, and stir until thoroughly mixed." *U. S.*

"Phenol, 1 ounce (Imperial) or 20 grammes; Glycerin, sufficient to produce 5 fl. ounces (Imp. meas.) or 100 cubic centimetres. Triturate the Phenol with the Glycerin until solution is effected." *Br.*

Uses.—For the uses of this preparation, see *Phenol*. The *U. S.* (8th Rev.) glycerite is a 20 per cent. by volume solution of liquefied phenol; the British preparation is slightly stronger, being a 20 per cent. by volume solution of crystallized phenol. It may be used internally or locally, and for both purposes should in general be diluted with water at the time of application.

Dose, from five to ten minims (0.3 to 0.6 Cc.).

GLYCYRRHIZA. U. S. (Br.)

GLYCYRRHIZA LICORICE ROOT

(glŷċ-yr-rhĭ'zā)

"The dried rhizome and root of *Glycyrrhiza glabra* Linné (Spanish Licorice), or of *Glycyrrhiza glandulifera* Waldstein and Kitaibel (Russian Licorice) (Fam. *Leguminosae*)."
U. S. "The peeled root and peeled subterranean stem of *Glycyrrhiza glabra*, Linn., and other species." *Br.*

Glycyrrhizæ Radix, *Br.*; Radix Glycyrrhizæ Hispanica; Liquorice Root, Spanish Licorice Root; Régisse, *Fr. Cod.*; Racine de Régisse, Bois doux, Racine douce, Bois de Régisse, *Fr.*; Radix Liquiritiæ, *P. G.*; Spanisches Süßholz, Spanische Süßholzwurzel, Süßholzwurzel, *G.*; Liquiritia, *It.*; Regaliz (Raiz de), Orozuz, Palo dulce, *Sp.*

Glycyrrhiza glabra, Willd., *Sp. Plant.* iii. 1144; Woodv., *Med. Bot.* p. 420, t. 152; Carson, *Illustr. of Med. Bot.*, i. 38, pl. 32.—The licorice

¹ *Fluid Hydrastis*.—H. C. Bradford gives the following formula: Hydrastine hydrochloride, 20 gr.; Glycerin, 8 fl. oz.; Distilled Water, 16 fl. oz. Mix and filter. It is advisable to keep this preparation in amber bottles. (*West. Drug.*, 1902, 59.)

plant has a perennial root, which is round, succulent, tough, and pliable, furnished with sparse fibres, rapid in its growth, and in a sandy soil penetrates deeply into the ground. The stems are herbaceous, erect, and usually four or five feet in height, have few branches, and are garnished with alternate, pinnate leaves, consisting of several pairs of ovate, blunt, petiolate leaflets, with a single leaflet at the end, of a pale-green color, and clammy on their under surface. The flowers are violet or purple, formed like those of the pea, and arranged in axillary spikes supported on long peduncles. The calyx is tubular and persistent. The fruit is a compressed, smooth, acute, one-celled legume, containing from one to six small kidney-shaped seeds. There are two very distinct varieties of the plant yielding the root: the typical form, which is smooth throughout, and the variety, now recognized by the U. S. Pharmacopœia as a distinct species, *G. glandulifera*, W. K., in which the stem, leaves, and pods are more or less roughly glandular or pubescent.

The habitat of the plant is wide-spread, extending from the shores of the Mediterranean to Siberia as far north as latitude 55°, and southward through Asia Minor and Persia to Farther India. The licorice plant is cultivated in England,¹ the north of France, and Germany. It is also largely produced in the north of Spain, where it is an important article of commerce, and in Asia along the banks of the Tigris and Euphrates. It is probable that a portion of the root from Italy and Sicily is the product of *G. echinata*, which grows wild in Apulia. This species is also abundant in the south of Russia, where, according to Hayne, sufficient extract is prepared from it to supply the whole Russian empire. Large quantities of licorice root are now imported for the purpose of making the extract, the imports for 1902 having been 109,077,323 lbs., valued at \$1,926,903; for 1903, 88,580,611 lbs. valued at \$1,545,167; and for 1904, 89,463,182 lbs., valued at \$1,472,323.

A species of *Glycyrrhiza*, *G. lepidota*, grows abundantly about St. Louis, in the State of Missouri, and flourishes along the banks of the Missouri River to its source. It is probably the same as the licorice plant mentioned by Mackenzie as growing on the northern coast of this continent. Nuttall states that its root possesses in no inconsiderable degree the taste of licorice, and M. L. McCulloch found it to contain 6.39 per cent. of crude glycyrrhizin, in contrast with 7.18 per cent. in the official species. (*A. J. P.*, 1890.)

Properties.—The licorice root of commerce is in long pieces, varying in thickness from a few lines to two inches, fibrous; when not peeled, externally grayish brown and longitudinally wrinkled by desiccation, often warty, internally yellowish, pliable, tough, without odor, and of a sweet characteristic taste, mingled with a slight degree of acrimony. The two varieties are described in the U. S. Pharmacopœia as follows:

Spanish Licorice.—Cylindrical, usually cut into pieces 14 to 20 Cm. or more long, 5 to 15 Mm. thick; longitudinally wrinkled, grayish-brown or dark-brown, pliable; fracture coarsely fibrous; internally tawny-yellow; bark 1 to 3 Mm. thick; wood porous, in narrow wedges; odor slight; taste sweetish and slightly acid.

Russian Licorice.—Somewhat tapering, frequently 1 M. or more in length, 1 to 5 Cm. in diameter, deprived of the outer corky layer, when it is externally pale yellow; internally of a lighter yellow; wood rather soft; taste less sweet than that of the Spanish Licorice. Any blackened, knotty, bitter portions should be removed." *U. S.*

Formerly commerce was chiefly supplied with licorice root by Italy and Spain, but the amount coming from these sources is at present probably not more than 10 per cent. of the whole, the greater portion coming from Southern Russia, a large amount from Anatolia and Syria, and a little from Turkey and Persia. The Spanish variety has been most esteemed, but, according to H. N. Rittenhouse, the peeled Russian licorice is richer in glycyrrhizin and extractives than is any other variety, and is in fact the most valuable. Russian licorice is usually very large, quite sweet, but at the same time rather more bitter and acid than is the Spanish variety. Licorice root is often worm eaten and more or less decayed; such root should be rejected, as should also the small fibrous roots often shipped from Spain. The best pieces are large, bright yellow internally, and have the layers and the bark distinct. The bark is chiefly liber, consisting of parenchymatous tissue with bast-cells (which are stained yellow by iodine), and arranged so as to make ordinary liber bundles, and also a sort of network.

A character said by Rothrock (*A. J. P.*, 1884) to be diagnostic is the occurrence in the wood and parenchyma of bundles composed of numerous bast-cells, surrounded by a sheath of large cells containing crystals of calcium oxalate. In the Russian root the parenchymatous wood-cells are larger than in the Spanish. The powder is of a grayish-yellow color, when the root is pulverized without being deprived of its epidermis; of a pale sulphur-yellow, when the epidermis has been removed. Robiquet found the following ingredients in licorice root: 1, a peculiar transparent yellow substance, called *glycyrrhizin*, of a sweet taste, scarcely soluble in cold water, very soluble in boiling water, with which it gelatinizes on cooling,

¹ Most of the licorice root of commerce appears to be the product of wild plants, but it has been successfully cultivated in England (*A. J. P.*, 1874, 473) and in Syria. (*P. J.*, xvi. 647.) Although the attempts to produce it in the United States have hitherto met with no great success, we can see no reason why in some of the lowlands of the Southeastern States it should not flourish. An interesting report upon the production of licorice root in Spain was made by H. C. Marsten, United States consul, and may be found abstracted in *N. R.*, Jan. 1882.

thrown down from its aqueous solution by acids, readily soluble in cold alcohol, insusceptible of the vinous fermentation, yielding no oxalic acid by the action of nitric acid, and therefore wholly distinct from sugar; 2, a crystallizable principle named *agedoite* by Robiquet, but subsequently proved to be identical with *asparagin*; 3, starch; 4, albumen; 5, a brown acrid resin; 6, a brown nitrogenous extractive matter; 7, lignin; 8, salts of calcium and magnesium, with phosphoric, sulphuric, and malic acids. Flückiger states that a small amount of tannin is also always contained in the root, or rather its bark. The chief constituent, *glycyrrhizin*, Gorup-Besanez (*Ann. Ch. Ph.*, 118) considered to be a glucoside, as on boiling with diluted acids it breaks up into *glycyrrhetin* and an uncrystallizable sugar capable of fermentation. Roussin (*J. P. C.*, July, 1875) found that the sweet taste of the root was not owing to the free glucoside, but to its compound with ammonia.

Habermann (*Ann. Ch. Ph.*, 197) found that *glycyrrhizin-ammonia* was the acid ammonium salt of *glycyrrhizic acid*, a nitrogenous acid, and gave the formula $C_{44}H_{82}NO_{18}.NH_4$ for it. (See *Glycyrrhizinum Ammoniatum*.) He succeeded in extracting from the commercial "ammoniacal *glycyrrhizin*," *glycyrrhizic acid*, which may be considered to be the active constituent of licorice. It was obtained by dissolving the crude *glycyrrhizin* in glacial acetic acid at a boiling temperature, rapidly filtering, again treating the crystalline parts of the filtrate in the same manner, and finally purifying by repeated crystallizations from 90 per cent. alcohol. Its properties are peculiar, and account to a great extent for the singular behavior of liquid licorice preparations. With water, in which the substance is but little soluble at ordinary temperature, it forms a transparent, faintly yellow jelly. On mixing 1 Gm. of the body with 100 Cc. of water, the mixture after a few hours becomes so jelly-like that the open vessel may be inverted without losing any substance. It is insoluble in ether, but slightly soluble in absolute alcohol (even boiling), more so in alcohol of 90 per cent., and especially so when hot. Its solubility increases with the decrease of the percentage of alcohol. The apparent glucosidal character of *glycyrrhizic acid* Habermann explains by the fact that it breaks up on boiling with diluted sulphuric acid into *glycyrrhetin* and *parasaccharic acid*, according to the reaction:

(*Ann. Ch. Ph.*, 197; *N. R.*, Sept. 1879.) By fusing *glycyrrhizin* with potassium hydroxide, Weselsky and Benedikt (*Ber. d. Chem. Ges.*, 1876) obtained *paraoxybenzoic acid*.

Uses.—*Glycyrrhiza* is an excellent demulcent, well adapted to *pulmonic catarrhs*, and even to irritations of the mucous membrane of the bowels and urinary passages; but it is chiefly

used for the purpose of concealing the taste or of covering the acrimony of various drugs, such as ammonium chloride or quinine. A decoction may be prepared by boiling an ounce of the bruised root, for a few minutes, in a pint of water, but at present the extract is almost universally preferred. The powder is used in the preparation of pills, either to give due consistence or to cover their surface and prevent them from cohering, and as a diluent in powdered extracts.

GLYCYRRHIZINUM AMMONIATUM. U. S.

AMMONIATED GLYCYRRHIZIN

(glÿc-yr-rhî-zî'nûm' am-mō-nî-ā'tûm)

Glycyrrhizine Ammoniacale, Fr. Cod.; *Glyzina, Glyzine, Fr.*; *Ammoniak-Glycyrrhizin, G.*

* "*Glycyrrhiza*, in No. 20 powder, five hundred grammes [or 17 ounces av., 279 grains]; Water, Ammonia Water, Sulphuric Acid, each, a sufficient quantity. Mix four hundred and seventy-five cubic centimeters [or 16 fluid-ounces, 30 minims] of Water with twenty-five cubic centimeters [or 406 minims] of Ammonia Water, and, having moistened the powder with the mixture, macerate for twenty-four hours. Then pack it moderately in a conical glass percolator, and gradually pour water upon it until five hundred cubic centimeters [or 16 fluid-ounces, 435 minims] of percolate are obtained. Add Sulphuric Acid slowly to the percolate, with constant stirring, so long as a precipitate is produced. Collect this on a strainer, wash it with cold Water until the washings no longer have an acid reaction, redissolve it in Water with the aid of Ammonia Water, filter, if necessary, and again add Sulphuric Acid so long as a precipitate is produced. Collect this, wash it, dissolve it in a sufficient quantity of Ammonia Water previously diluted with an equal volume of Water, and spread the clear solution upon plates of glass, so that, when dry, the product may be obtained in scales." *U. S.*

This is a preparation whose introduction is a result of the very important researches of Z. Roussin, communicated to the Société de Pharmacie of Paris, June 2, 1875. This investigator noticed that *glycyrrhizin*, the sweet principle of licorice root, is insipid when compared with

the root itself, and suspected that it existed in a modified form in the root. Experiment showed that alkalies developed the sweet taste, and he ultimately proved that the alkali with which it was combined in the root was ammonia, and that glycyrrhizin played the part of an acid. He named the compound *ammonium glycyrrhizate*, and called attention to the fact that licorice root which had lost a portion of its sweetness through fermentation and the development of acetic acid and precipitation of insoluble glycyrrhizin could be restored to its former sweetness if allowed to remain a sufficient length of time in an ammoniacal atmosphere. The official process for ammoniated glycyrrhizin is closely modelled after Roussin's, with the exception of the substitution of percolation by a slightly ammoniated menstruum for maceration and expression with cold water. Roussin purified his product by redissolving it in alcohol and precipitating with ether; this is deemed unnecessary for a preparation which is intended to be useful without being expensive. (See *Proc. A. Ph. A.*, 1876, p. 544.)

Connerade has proposed some modification of Roussin's method; his process is as follows: "Macerate ground liquorice root with one and a half parts by weight of water, strain, wash the residue with a very small quantity of water, heat the mixed liquids to boiling to coagulate albumen, strain again, and then add diluted sulphuric acid (1 in 10), as long as a precipitate is produced. Let this settle, decant the liquid, and dissolve the precipitate in solution of ammonia, diluted with nine parts of water. Filter the latter and evaporate it to dryness. The compound then remains as a brown, friable varnish, unaltered by air, of a pure, sweet taste, easily soluble in cold water, and imparting to the latter, even when diluted to 1 in 1000 parts, an amber color. The yield is about 10 per cent. of the weight of the root." (*N. R.*, March, 1881.)

Properties.—The following is the description given in the U. S. Pharmacopœia: "Dark brown or brownish-red scales, without odor, and having a very sweet taste. Readily soluble in water and in alcohol. The aqueous solution, when heated with potassium hydroxide T.S., evolves ammonia. If the aqueous solution be supersaturated with an acid, there will be produced a precipitate (glycyrrhizin) which, when dissolved in hot water, forms a jelly on cooling. This substance, after being washed with diluted alcohol and dried, appears as an amorphous, yellow powder, having a strong, bitter-sweet taste, and an acid reaction. Upon incineration, Ammoniated Glycyrrhizin should not leave more than a trace of ash." U. S.

Uses.—This substance appears to possess the medicinal properties of licorice, and may be used as an elegant substitute for it in mixtures which are neither acid nor alkaline.

Dose, from five to fifteen grains (0.32 to 1.0 Gm.).

GOSSYPHII CORTEX. U. S. (Br. Add.)

COTTON ROOT BARK [*Gossypii Radicis Cortex*, Pharm. 1890]

(goss-sŷp'ī cōr'tēx)

"The dried bark of the root of *Gossypium herbaceum* Linné, or of other cultivated species of *Gossypium* (Fam. *Malvaceæ*)." U. S.

Gossypii Radicis Cortex, Br. Add.: Ecorce de la Racine de Cotonnier, Fr.; Baumwoll-Wurzelrinde, G.; Corteza de la raíz d'algodon, Sp.

In consequence of changes produced in the plants of this genus by cultivation, botanists have found great difficulty in determining which are distinct species and which are merely varieties. De Candolle describes thirteen species in his *Prodromus*, and mentions six others, but considers them all uncertain. Royle describes eight and admits others. Schwartz thinks that they may all be referred to one original species. Engler and Prantl recognize six species, three of these being cultivated. The plants inhabit different parts of tropical Asia and Africa, and many of them are cultivated for their cotton in climates adapted to their growth. The species from which most of the cotton of commerce has been thought to be obtained is the one specially indicated by the U. S. Pharmacopœia. According to Royle, it is the India cotton which is produced by *G. herbaceum*, while *G. barbadense* furnishes all the cotton of North America, and *G. peruvianum* that produced in Brazil, Peru, and other parts of South America. (See A. J. P., 1858, 339.) A. W. Chapman, however, in his *Flora of the Southern United States* (New York, 1860, 58,), states that the numerous varieties of the cotton plant are now referred to two species, the *long staple*, or *sea island*, to *G. album* (Haw.), and the *short staple*, or *upland*, to *G. nigrum* (Haw.). For an account of a microscopical and microchemical examination of cotton root bark by F. W. Morgan, see A. J. P., 1898, 427.

Gossypium herbaceum, Linn., *Sp. Plant.* 975; De Cand., *Prodrom.* i. 456.—This is a biennial or triennial plant, with a branching stem from two to six feet high, and palmate hoary leaves, the lobes of which are somewhat lanceolate and acute. The flowers are pretty, with yellow petals, having a purple spot near the claw. The leaves of the involucre or outer calyx are serrate. The capsule opens when ripe, and displays a loose white tuft of long slender filaments, which surround the seeds and adhere firmly to the outer coating. The plant is a native of Asia, but is cultivated in most tropical countries. It requires a certain duration of warm weather to perfect its seeds, and, in the United States, does not mature north of Virginia.

The herbaceous part of the plant contains much mucilage, and has been used as a demulcent. The seeds yield by expression a fixed oil of the drying kind, which is employed for making soap and for other purposes. (See

Oleum Gossypii.) The bark of the root has been supposed to possess medicinal virtues, and is recognized by the U. S. Pharmacopœia. Another official portion, and that for which the plant is cultivated, is the filamentous substance surrounding the seeds. This when separated constitutes the cotton of commerce. Cotton seeds have been employed in our Southern States with great asserted success in the treatment of intermittents, but are at present seldom, if ever, used. (For details, see U. S. D., 16th ed.)

Properties.—Cotton Root Bark is officially described as "in thin, flexible bands or quilled pieces, the bark 0.2 to 1 Mm. thick; outer surface yellowish-brown, longitudinally wrinkled, with small lenticels, the periderm frequently exfoliated and somewhat fuzzy from partly detached bast fibres; inner surface whitish, longitudinally striate; fracture tough, fibrous, the bast-layer separable into thin laminae; odor faint; taste slightly astringent and acrid." U. S. E. S. Wayne of Cincinnati, found in it a peculiar acid resin, colorless and soluble in water, when pure, but absorbing oxygen on exposure, and then becoming red and insoluble in water. It is deposited by the fluidextract on standing. He suggests that this may be the active principle of the root; but the fact has not been determined. (A. J. P., 1872.) William C. Staehle (A. J. P., 1875) made an examination of this resin, and obtained results somewhat different from those of Wayne. Staehle's percolate was of a dark reddish-brown color, while Wayne's was pale amber. This is accounted for, however, by the presence of a principle which is colorless in the fresh bark, but of a dark red in bark which has been exposed to air and light. W. A. Taylor noticed that the change in color from pale amber to dark red took place in an alcoholic tincture. (A. J. P., 1876.) Staehle found the resin soluble in 14 parts of alcohol, 15 parts of chloroform, 23 parts of ether, and 122 parts of benzene.

Uses.—Bouchelle of Mississippi, first stated that cotton root is an excellent emmenagogue, and was habitually resorted to by the slaves of the South for producing abortion. To assist labor, he employed a decoction made by boiling four ounces of the inner bark of the root in a quart of water to a pint, and gave a wineglassful (60 Cc.) every twenty or thirty minutes. (W. J. M. S., Aug. 1840.) These opinions of Bouchelle have been confirmed by various Southern medical practitioners, and H. I. Garrigues asserts that the cotton root has great powers in arresting hemorrhage and ameliorating the other symptoms of *uterine fibroids*, but, for some reason, the drug failed to come into general use. Bellany of Columbus, Georgia, found that the root should be gathered as late as possible in the fall before frost. The fluidextract official in the U. S. P. 1890 (see page 525) may be used in doses of from one-half to one fluidrachm (1.8 to 3.75 Cc.), re-

peated at short intervals if necessary. The British Addendum recognizes a decoction of Cotton Root Bark.¹

Dose, thirty to sixty grains (2 to 3.9 Gm.).

GOSSYPIMUM PURIFICATUM.

U. S. (Br.)

PURIFIED COTTON [Absorbent Cotton]

(gòs-sýp'í-ùm pû-rí-fj-cá'tùm)

"The hairs of the seed of *Gossypium herbaceum* Linné, or of other cultivated species of *Gossypium* (Fam. *Malvaceæ*) freed from adhering impurities and deprived of fatty matter." U. S. "The hairs of the seed of *Gossypium barbadense*, Linn., and of other species of *Gossypium*, freed from fatty matter." Br.

Gossypium, Br.: Cotton Wool; Lana (Lanugo, s. plii) *Gossypii*; Coton Hydrophile, Fr. Cod.; Coton absorbant, Xylum præparatum, Fr.; *Gossypium depuratum*, P. G.; Gereinigte Baumwolle, Baumwolle, G.; Cotone asséché, C. idrofilo, It.; Algodon hidrofílo, Algodon absorbente, Sp.

Cotton consists of "white, soft, fine filaments, appearing under the microscope as hollow, flattened and twisted bands, spirally striate, and slightly thickened at the edges; inodorous and tasteless; insoluble in ordinary solvents, but soluble in an ammoniacal solution of cupric oxide." U. S. It is without odor or taste, soluble in strong alkaline solutions, and decomposed by the concentrated mineral acids. In chemical character it is related to but not identical with lignin, the latter being an alteration product and sometimes called *oxy-cellulose*. By nitric acid it is converted into that remarkable explosive substance denominated *gun cotton*, for an account of which see *Pyroxylinum* and *Collodium*. *Mercerized cotton* (imitation of silk) is made by boiling the raw cotton in a diluted alkaline solution.

In the process of purifying cotton a soap is formed through the union of the fatty matter with the alkali, and this is subsequently dissolved out by repeated washings. F. L. Slocum published in 1881 a process for preparing it. For details see the foot-note.² The U. S. P.

¹ *Decoction Gossypii Radicis Corticis*, Br. Add., *Decoction of Cotton Root Bark*.—Cotton Root Bark, bruised, 4 ounces (Imperial) [200 grammes]; Distilled Water, a sufficient quantity. Boil the Cotton Root Bark with two pints (Imp. Meas.) [or two litres] of the Distilled Water, in a suitable vessel, until the volume is reduced to one pint (Imp. Meas.) [or one thousand cubic centimetres], strain, if necessary pour more Distilled Water over the contents of the strainer, so as to produce one pint (Imp. Meas.) [or one thousand cubic centimetres] of the strained Decoction.

² *Purified Cotton*.—Take of the best quality of carded cotton batting any desired quantity, and boil it with a 5 per cent. solution of potassium or sodium hydroxide for one-half hour, or until the cotton is entirely saturated with the solution, and the alkali has saponified all oily matter. Then wash thoroughly, to remove all soap, and nearly all alkali; press out the excess of water, and immerse in a 5 per cent. solution of chlorinated lime for 15 or 20 minutes; again wash, first with a little water, then dip in water acidulated with hydrochloric acid, and thoroughly wash with water; press out the excess of water, and again boil for 15 or 20 minutes in a 5 per cent. solution of potassium or sodium hydroxide; now wash well,

tests are as follows: "When Purified Cotton, previously compressed in the hand, is thrown on the surface of cold water, it should readily absorb the latter and sink, and the water should not acquire either an acid or an alkaline reaction (evidence of proper purification and absence of fatty matter). Purified Cotton should be perfectly free from all visible impurities, and on combustion should not leave more than 0.3 percent. of ash." *U. S.* The first test proves the absence of fatty matter, for if even a small quantity be present the cotton will float in water. Repeated experiments have proved that cotton will take fire and burn spontaneously if impregnated with linseed oil, or some of the other fixed oils, and allowed to stand, whereby the heat of the oxidation of the oil suffices to ignite the matted fibres of the cotton. (*P. J.*, 1872, p. 225.) Cotton, analyzed by M. Schunck, was found, independently of cellulose ($C_6H_{10}O_5$)_n, of which it chiefly consists, to contain vegetable wax, a fatty acid, coloring matter, pectic acid, and a little of an albuminoid substance. (*J. P. C.*, Sept. 1868, 233.) For medicinal use it should be carded into thin sheets.¹ It is said that air passed through cotton loses the property of inducing fermentation, on account of the microscopic organisms being strained out of it; and this fact has been utilized in preserving infusions by placing them in bottles containing corks armed with tubes loosely filled with cotton, and drawing the infusion from a stopcock near the bottom.

Uses.—The use of cotton as a filtering medium and in the preparation of medicated waters has already been alluded to. It is much used in surgery as a dressing for burns, scalds, blisters, and wounds, in order to prevent the access of pathogenetic germs.² Cotton batting

dipping in the acidulated water and washing thoroughly with pure water. Afterwards press out and dry quickly.

The amount of loss by this process is practically 10 per cent. A sample of 360 gr. lost, on boiling with alkali and bleaching, 15 gr., or 4.17 per cent., and 270 gr. of this bleached sample lost, on again boiling with an alkali, 14 gr., or 5.18 per cent., a total loss of 9.35 per cent. (*A. J. P.*, 1881, p. 53. See also *Ph. Era*, 1890, 22.)

¹ **Wood Wool.**—Under this name Bruns has introduced finely grained, purified wood fibre, such as is used in making paper. It may be medicated like cotton. (*N. R.*, 1883, p. 361.)

² Absorbent cotton has been medicated in various ways and come largely into use. (See *Iodized Cotton*, under *Iodum*.) *Picric Cotton* is prepared by dissolving 0.25 Gm. of picric acid in 25 Gm. of ether, or 94 per cent. alcohol, and immersing in the solution 10 Gm. of clean cotton, and drying. *Salicylic Cotton* (5 per cent.) may be prepared by Bruns's process, by saturating one kilogramme of cotton with 4 liters of a solution of 50 Gm. of salicylic acid and 20 Gm. of castor oil in 3,330 liters of alcohol. *Benzolic Cotton* is made in the same way, substituting benzoic for salicylic acid. (*A. J. P.*, Dec. 1878.) *Chlorinated Cotton.* Pavesi subjects cotton moistened with glycerin, and suspended at the top of a large wide-mouthed bottle, to the action of chlorine vapor, generated by adding sulphuric acid to chlorinated lime. (*N. R.*, July, 1880.) Joseph W. England communicates in *A. J. P.*, 1887, p. 173, practical formulas for preparing the following medicated cottons and gauzes: *Borated Cotton*, *Benzolated Cotton*, *Salicylated Cotton*, *Naphthalinated Cotton*, *Iodoformized Cotton*, *Carbolized Cotton*, *Sublimated Cotton*, *Carbolized Gauze*, *Sublimated Gauze*, *Absorbent Cotton Flannel*. For methods of assay of medicated cottons, gauzes, etc., see *Proc. A. Ph. A.*, 1897, 457, 458, 459.

is often employed to maintain a uniform temperature in parts affected with acute rheumatic inflammation.

Off. Prep.—Pyroxylinum, *Br.*

GRANATUM. U. S. (Br.)

POMEGRANATE

(grā-nā'tūm)

"The bark of the stem and root of *Punica Granatum* Linné (Fam. *Punicaceæ*)." *U. S.* "The dried bark of the stem and root of *Punica Granatum*, Linn." *Br.*

Granati Cortex, Br., Pomegranate Bark; Grenadier, *Fr. Cod.*; Ecorce de la Racine de Grenadier (de Balaustier), Ecorce de Granade, *Fr.*; Cortex Granati, *P. G.*; Granatrinde, Granatwurzelsrinde, *G.*; Melogranato, Mallicorio, Scorza del Melogranati, *It.*; Granada (Corteza de), *Sp.*

Punica Granatum, Willd., *Sp. Plant.* ii. 981; Woodv., *Med. Bot.* p. 531, t. 190; Carson, *Illustr. of Med. Bot.*, i. 45, pl. 38.—The pomegranate is a small shrubby tree, attaining in favorable situations the height of twenty feet, with a very unequal trunk, and numerous branches which sometimes bear thorns. The leaves are opposite, entire, oblong or lance-shaped, pointed at each end, smooth, shining, of a bright-green color, and placed on short footstalks. The flowers are large, of a rich scarlet color, and stand at the end of the young branches. The petals are roundish and wrinkled, and are inserted into the upper part of the tube of the calyx, which is red, thick, and fleshy. The fruit is a globular berry, about the size of an orange, crowned with the calyx, covered with a reddish-yellow, thick, coriaceous rind, and divided internally into many cells, which contain an acidulous pulp, and numerous oblong, angular seeds.

This tree grows wild upon both shores of the Mediterranean, in Arabia, Persia, Bengal, China, and Japan, has been introduced into the East and West Indies, and is cultivated in all civilized countries where the climate is sufficiently warm to allow the fruit to ripen. In higher latitudes, where it does not bear fruit, it is raised in gardens and hot houses for the beauty of its flowers, which become double and acquire increased splendor of coloring by cultivation. Doubts have been entertained as to its original country. The name of *Punicum Malum*, applied by the ancients to its fruit, implies that it was abundant at an early age in the vicinity of Carthage. The fruit, for which the plant is cultivated, varies much in size and flavor. It is said to attain greater perfection in the West Indies than in its native country. The edible pulp is red, succulent, pleasantly acid, and sweetish. The flowers were recognized by the Dublin College, and the seeds are official in France. See a paper by J. U. Lloyd in *West. Drug.*, 1897, 202.

Rind of the Fruit.—This is presented in commerce under the form of irregular fragments,

hard, dry, brittle, of a yellowish or reddish-brown color externally, paler within, without odor, and of an astringent, slightly bitter taste. It contains a large proportion of tannin, and in countries where the tree abounds, has been employed for tanning leather.

Flowers.—The flowers, sometimes called *ba-laustines*, are inodorous, have a bitterish, astringent taste, and impart a violet-red color to the saliva. They contain tannic and gallic acids, and were used by the ancients in dyeing.

Bark.—The stem bark is officially described as "in single quills or transversely curved pieces, mostly 2 to 10 Cm. long, 5 to 20 Mm. in diameter; bark 0.5 to 3 Mm. thick; outer surface yellowish- to brownish-gray, with brownish-black fruit-heads of a lichen and small lenticels; inner surface grayish-yellow to brownish, finely striate; fracture short, smooth, the phelloderm layer dark green, the inner bark dull greenish-yellow; odor distinct; taste astringent, somewhat bitter." *U. S.* The roots of the pomegranate are hard, heavy, knotty, ligneous, and covered with a bark which is yellowish-gray or ash-gray on the outer surface, and yellow on the inner. The root bark occurs in quills or fragments similar to but differing from those of the stem as shown in the official characterization.¹ "Dark brown, with more or less longitudinal patches and scales of cork; green phelloderm layer absent; medullary rays extending nearly to the periderm." *U. S.* "The transverse section exhibits numerous fine radial and tangential lines." *Br.* It has little or no odor, colors the saliva yellow when chewed, and leaves in the mouth an astringent taste without disagreeable bitterness. The infusion of the bark yields a deep-blue precipitate with salts of iron, and a yellowish-white precipitate with solution of gelatin. The inner surface of the bark, steeped in water and then rubbed on paper, produces a yellow stain, which by the contact of ferrous sulphate is rendered blue, and by that of nitric acid acquires a slight rose tint, which soon vanishes. These properties serve to distinguish this bark from those of the box root and barberry, with which it is said to be sometimes adulterated. When used, it should be separated from the ligneous portion of the root, as the latter is inert. The bark contains more than 22 per cent. of tannic acid, which Rembold (*Ann. Ch. Ph.*, 143, 285) found

to consist for the most part of a peculiar variety, *punico-tannic acid*, $C_{20}H_{18}O_{12}$; when boiled with diluted sulphuric acid it is resolved into *ellagic acid*, $C_{14}H_8O_8$, and sugar. Punico-tannic acid is accompanied by common tannic acid, yielding by means of sulphuric acid, gallic acid, which appears sometimes to pre-exist in the bark. Henry Trimble, however, (*A. J. P.*, 1897, 636), as the result of an ultimate analysis of the purified tannin and a study of its reactions, pronounced it to be identical with gallotannic acid. Pomegranate bark also yields a considerable quantity of *mannite*, which was formerly described under the names of *punicin* or *granatin*. The active power of the root, however, is due, according to Tanret (*C. R. A. S.*, 86, 1270, and 87, 358), to an alkaloid *pelletierine*, $C_9H_{15}NO$, a dextrogyrate liquid boiling at $195^\circ C.$, easily soluble in water, alcohol, and ether, and specially so in chloroform. It has strong basic properties and precipitates many metallic salts: 1000 parts of dry bark yielded 4 parts of it.

In a later communication (*C. R. A. S.*, 88, p. 716), Tanret announced that he had found three additional volatile bases in the bark, a liquid left-rotating one, a liquid optically inactive one, and a crystallizable inactive one, which latter has the formula $C_9H_{15}NO + 2H_2O$, fuses at $46^\circ C.$, and boils at $246^\circ C.$ His process for obtaining these alkaloids is as follows. A mixture of the salts of the alkaloids is prepared by mixing the powdered bark with a milk of lime, exhausting with water, shaking the resulting liquor with chloroform, and neutralizing the latter with diluted acid. A solution of the mixed alkaloids is thus obtained in which one or other of them predominates, according to the source of the bark. Two of the four alkaloids are displaced from their salts by sodium bicarbonate, and two are not. The solution is therefore treated with an excess of sodium bicarbonate and shaken with chloroform, and this in its turn is agitated with diluted sulphuric acid. The resulting solution contains the sulphates of two alkaloids, to which the names of *methylpelletierine*, $C_9H_{17}NO$, and *pseudopelletierine*, $C_9H_{15}NO$, have been given. Potassium hydroxide is then added to the first liquor, and upon repeating the treatment with chloroform and acid there is obtained a solution of *pelletierine* and *isopelletierine* sulphates. (*P. J.*, 1880.) Carl J. Bender (*Ph. Centralk.*, 1885, p. 6) found three bases in pomegranate bark, one crystallizable and two amorphous. He objects to the name *pelletierine*, and substitutes *punicine*. Wm. F. Junkunz analyzed pomegranate bark, and believed that the alkaloid exists in the bark as a tannate. (*A. J. P.*, 1884.) The old idea that the bark loses activity when kept seems to be negated by the analysis of De Vrij. (*P. J.*, xxi.) Piccinini isolated a tertiary alkaloid, $C_{10}H_{15}NO$, from pomegranate root bark (*P. J.*, 1900, 249). For Leger's method of determining total alkaloids see *P. J.*, 1904, 581.

¹ The bark of the stem of the pomegranate is sold as root bark: for microscopic diagnosis, see *P. J.*, 1873. As the activity of the barks of different portions of the plant is important, represented by the alkaloids the analyses of Stoeder are of interest. His results are: stem and branch bark, in thin quills, 0.612 per cent.; average quills, 0.350 per cent.; thick quills, 0.498 per cent.; root bark from south of Europe, in thick quills, 1.010 per cent.; shaved root bark from Java, 1.326 per cent.; exfoliated bark from dry thick roots of unknown age, 1.240 per cent.; finely rasped wood from these roots, 0.218 per cent. According to the same authority (*Nederl. Tijds. Pharm.*, 1890), of the bark of three varieties of the wild pomegranate recognized and used by the natives of Java, the red-flowered "*merah*," yielded 2.43 per cent.; the white-flowered, "*poeth*," yielded 3.75 per cent.; the black-flowered, "*hitam*," yielded 1.71 per cent.

Uses.—The rind of the pomegranate fruit was formerly recognized by the U. S. Pharmacopœia. It is astringent, and in the form of decoction is sometimes employed in *diarrhœa* and *colliquative sweats*, and, more frequently, as an injection in *leucorrhœa*, and as a gargle in *sore throat* in the earlier stages, or after the inflammatory action has in some measure subsided. The powdered rind has also been recommended in *intermittent fever*. The flowers have the same medicinal properties and are used for the same purposes. The bark of the root was used by the ancients as a vermifuge, and is recommended in the writings of Avicenna, but was unknown in modern practice until brought into notice by F. Buchanan, who learned its powers in India. The Mahometan physicians of Hindostan consider it a specific against *tœnia*. One of these practitioners, having relieved an English gentleman in 1804, was induced to disclose his secret, which was then made public. The French writers prefer the product of the wild pomegranate, growing on the borders of the Mediterranean, to that of the plant cultivated in gardens for ornamental purposes. The bark may be administered in powder or decoction, but the latter form is usually preferred. The decoction is prepared by macerating two ounces of the bruised bark in two pints of water for twenty-four hours, and then boiling to a pint. Of this a wineglassful may be given every half hour, hour, or two hours, until the whole is taken. It often nauseates and vomits, and usually purges. Portions of the worm often come away soon after the last dose. It is recommended to give a dose of castor oil and to diet the patient strictly on the day preceding the administration of the remedy, and, if it should not operate on the bowels, to follow it by castor oil, or an enema. If not successful on the first trial, it should be repeated daily for three or four days, until the worm is discharged. It appears to have been used by the negroes of San Domingo before its introduction into Europe.

The efficacy of pelletierine as a tœnicide has been abundantly confirmed, and it appears to be established that the tannate is the most effective and the least dangerous form of the remedy,—probably because its insolubility prevents its rapid absorption and enables it to come in prolonged contact with the worm. The experiments of Dujardin-Beaumetz have shown that the alkaloids from pomegranate act upon the higher animals like curare, causing paralysis of the motor nerves without affecting sensation or muscular contractility. The same authority asserts that hypodermic injections of six grains produce in man severe vertigo, muscular weakness, and great retinal congestion. Double vision has also been noted, and Galezowski has been led by it to prescribe pelletierine in paralysis of the third and sixth pairs of nerves; he affirms that he has succeeded in affording relief after the failure of potassium

iodide and blisters. The proper dose of pelletierine tannate is variously given by authorities. It has been stated to be from one-half to three-quarters of a grain (0.032 to 0.048 Gm.) (*B. G. T.*, xvi., xvii.), but others place it as high as eight grains (0.5 Gm.). Commercially, it occurs almost exclusively as a syrupy solution, put up, we believe, under the supervision of its discoverer, each bottle containing a single dose, it is stated, of about five grains (0.32 Gm.). We have seen pronounced temporary general palsy produced in a female adult by this dose. The dose of pomegranate rind and flowers in powder is from twenty to thirty grains (1.3 to 2.0 Gm.). A decoction may be prepared in the proportion of an ounce of the bark to a pint of water, and given in the dose of a fluidounce (30 Ce.). The remedy should always be given after a twelve hours' fast, and be followed in two hours by a brisk cathartic. The seeds are demulcent.

Dose, twenty to thirty grains (1.3 to 2 Gm.).
Off. Prep.—Decoctum Granati Corticis, *Br.*;
 Fluidextractum Granati, *U. S.*

GRINDELIA. U. S., Br. Add.

GRINDELIA

(grin-dě'li-ə)

"The dried leaves and flowering tops of *Grindelia robusta* Nuttall, or of *Grindelia squarrosa* (Pursh) Dunal (Fam. *Compositæ*)."
U. S.

California Gum-plant; *Grindella*, *Fr.*; *Grindelle*, *G.*

This genus inhabits the western side of both North and South America. Most if not all of the species produce a resinous exudation, especially from the flower-heads, and it is probable that medicinal properties are common to the genus.

G. robusta, Nuttall, is an herbaceous plant, from one to three feet high, very glabrous, with leaves varying from broadly spatulate or oblong to lanceolate, or the upper cordate and clasping, commonly obtuse, sharply more or less serrate; the scales of the involucre are produced into long circinate, squarrose, awn-like tips; the pappus of two to three, rarely five, nearly smooth, flattish awns; akenes mostly one- to three-toothed at the apex.

G. squarrosa (Pursh), Dunal (Syn. *Donia squarrosa*, Pursh (1814), *G. squarrosa*, Dunal (1836)), is in general a less leafy and bushy plant than is *G. robusta*, but so closely resembles some varieties of the latter that, after a careful study of various published descriptions and of the specimens in the herbarium of the Philadelphia Academy of Natural Sciences, we are not satisfied of the specific distinctness. The character pointed out by Torrey and Gray, that in *robusta* the leaves are broader at the base than above does not hold, for in a specimen in the herbarium of the Academy of Natural Sciences labelled in

Nuttall's handwriting, and, therefore, probably the type of *G. robusta*, the leaves are not broader at the base; while in various specimens of *G. squarrosa* they are not narrowed at the base. The most constant distinctive characters in the specimens at hand are that *G. robusta* has a more leafy involucre and its leaves usually are more coarsely serrate; but Watson describes a variety of *G. robusta* in which the upper leaves are entire. There is no constant difference in the scales of the involucre. According to Joseph Beauvais (*A. J. P.*, Feb. 1889), the resin of the leaf of *G. robusta* is contained in epidermal glands, and also in rather large resin-ducts situated in an interior collenchymatous layer.

Properties.—The official description of grindelia is as follows: "Leaves about 5 Cm. or less long, varying from broadly spatulate or oblong to lanceolate, sessile or clasping, obtuse, more or less sharply serrate, often spinosely toothed, or even lacinate-pinnatifid, pale green, smooth, finely dotted, somewhat coriaceous, brittle; heads more or less resinous-viscid, many-flowered, either conical-urceolate (*G. squarrosa*), or depressed-urceolate (*G. robusta*); the involucre hemispherical, about 10 Mm. broad, composed of numerous imbricated, squarrosely tipped or spreading scales; ray-florets yellow, ligulate, pistillate, sometimes absent; disk-florets yellow, tubular, perfect; pappus of two or three mostly unequal awns about the length of the disk-florets; odor balsamic; taste pungently aromatic and bitter." *U. S.*

As it occurs in commerce, grindelia is in the form of the whole dried herb; the stems are about eighteen inches in length, light brownish, very frequently stripped of their leaves, but with some of the floral heads adherent. The brittle leaves are much broken, and with separated floral heads are mixed with the stem. The taste is warmish, peculiar, and very persistent. The specimens we have examined seemed to contain numerous floral heads, some according with those of the typical *G. robusta*, others without trace of involucre leaves. Some of the latter may have been removed, it is true, by accidents of carriage; but if *G. squarrosa* and *G. robusta* be distinct species, it would appear that they are indiscriminately collected. The activity of the drug probably resides in the resinous exudation. C. J. Rademaker obtained from it an oil, the odor of which closely resembled that of oil of turpentine, resin, and a crystalline body having an alkaline reaction. (*N. R.*, 1876, p. 205.) W. H. Clark and John L. Fischer (*A. J. P.*, 1888, p. 433) failed to verify all of Rademaker's results, but obtained an alkaline principle to which the name of *grindeline* was given. A. Schneegans (*A. J. P.*, 1892, 369) found in *Grindelia robusta*, saponin, which, he states, is composed of two glucosides; he also found indications of an alkaloid, but believes that its presence is not yet certainly proved. See also *M. R.*, 1898, 394. *Grindelia robusta* is said to contain

0.28 per cent. of a dark-brown essential oil, having a specific gravity of 0.9582 at 15° C., and the optical rotation in alcoholic solution of -8° 08'. It is soluble in ether, amyl alcohol, and chloroform. (*Ph. Ztg.*, 48, 574.)

Uses.—According to Buffington, when given to the lower animals in very large doses grindelia produces narcosis, with dilated pupils, slowing of the action of the heart from stimulation of the inhibitory nerves, and elevation of the blood pressure from stimulation of the vasomotor centre. Dobroklowsky has found that on the isolated frog's heart it acts in small doses as a stimulant and in large doses as a paralyzant; he further states that it acts chiefly upon the motor nerves and muscles, but Buffington asserts that it paralyzes first the sensory nerve-trunks, then the sensory side of the spinal cord, and afterwards involves the motor nerve-trunks and cord. Grindelia is not used in practical medicine for its influence upon the circulation, but as an antispasmodic, especially in *asthma*, and in *bronchitis* when there is a distinct tendency to dyspnea and bronchial spasm. It seems probable that it not only exerts an antispasmodic influence, but also stimulates the bronchial mucous membrane, and it may be confidently exhibited in chronic bronchitis, especially of the aged. It has been employed with asserted success in *whooping cough*. Its active principles appear to be excreted from the kidneys; hence after large doses there are sometimes evidences of renal irritation, and in chronic *catarrh* of the *bladder* good has been effected by its stimulant influence upon the mucous membrane of the viscous. As a local application, grindelia has been employed with asserted advantage in *burns*, *vaginitis*, *genito-urinary catarrh*, etc., applied either in the form of a poultice or in solution.

Dose, thirty to forty grains (2 to 2.6 Gm.).

Off. Prep.—Fluidextractum Grindeliæ, *U. S.*

GUAIACI LIGNUM. Br.

GUAIACUM WOOD

(gwaí'a-cí lîg'nûm)

"The heart-wood of *Guaiacum officinale*, *Linn.*, or of *Guaiacum sanctum*, *Linn.*" *Br.*

Lignum Sanctum (vel *Benedictum*); *Lignum Vitæ*; *Gayac*, *Fr. Cod.*; Bois de *Gayac*, *Fr.*; *Lignum Guaiaci*, *P. G.*; *Guajakholz*, *Franzosenholz*, *Pöckholz*, *G.*; *Guajaco*, *Legno guajaco*, *It.*; *Guayaco* (*Leño de*), *Sp.*

Guaiacum officinale, *Willd.*, *Sp. Plant.* ii. 538; *Woodv.*, *Med. Bot.* 557, t. 200; *Carson*, *Illustr. of Med. Bot.*, i. 25, pl. 17.—This is a large tree, of a very slow growth. When of full size it is from forty to sixty feet high, with a trunk four or five feet in circumference. The branches are knotted, and covered with an ash-colored striated bark. That of the stem is of a dark-gray color, variegated with greenish or purplish spots. The leaves are opposite, and abruptly pinnate, consisting of two, three, and sometimes four pairs of leaflets, which are

obovate, veined, smooth, shining, dark green, from an inch to an inch and a half long, and almost sessile. The flowers are of a rich blue color, stand on long peduncles, and grow to the number of eight or ten at the axils of the upper leaves. The seeds are solitary, hard, and of an oblong shape.

G. sanctum, L., is distinguished from *G. officinale* by its five-celled fruit and its oblong or obliquely obovate or sometimes rhomboid-ovate leaflets, six to eight to each leaf. It grows in Cuba and some other of the West India Islands, and in the Bahama Islands. Its wood is smaller than that of *G. officinale*, and is said by Fée to be paler and less dense.

G. officinale grows in the West Indies, particularly in Hayti and Jamaica, and is found also in the warmer parts of the neighboring continent. All parts of the tree are possessed of medicinal properties, but the wood and the concrete juice only are official. The bark, though much more efficacious than the wood, does not enter commerce. *G. arboreum* of De Candolle has been said to furnish some of the guaiacum wood of commerce.

Guaiacum wood is imported from Hayti and other West India islands, in the shape of logs or billets, covered with thick gray bark, which presents on its inner surface, and upon its edges when broken, numerous shining crystalline points. These were supposed by Guibourt to be benzoic acid, by others a resinous exudation from the vessels of the plant; but Otto Berg has determined that they are crystals of calcium sulphate. The billets are used by turners for the fabrication of various instruments and utensils, for which the wood is well adapted by its extreme hardness and density. It is kept by the druggists and apothecaries in the state of shavings or raspings, which they obtain from the turners. It is commonly called *lignum vita*, a name which obviously originated from the supposition that the wood was possessed of extraordinary remedial powers.

Properties.—Guaiacum wood is hard and heavy. The color of the sap-wood is yellow, that of the older and central layers greenish brown, that of the shavings a mixture of the two. It is said that when the wood is brought into a state of minute division its color is rendered green by exposure to the air, and bluish green by the action of nitric acid fumes, and the latter change may be considered as a test of its genuineness. (Duncan.) An easier test is a solution of corrosive sublimate, which, added to the shavings and slightly heated, causes a bluish-green color in the genuine wood. Guaiacum wood is almost without odor unless rubbed or heated, when it becomes odorous. When burned, it emits an agreeable odor. It is bitterish and slightly pungent, but requires to be chewed for some time before the taste is developed. It contains, according to Trommsdorf, 26 per cent. of resin, and 0.8 of a bitter pungent extractive, upon both of which, probably, though chiefly on the former, its medicinal vir-

tues depend. (See *Guaiacum*.) Paetzold (*Schim. Rep.*, 1902, 43) states that the bark of the guaiac tree yields 1 per cent. of a volatile oil, having an exquisite odor. The wood yields its virtues but partially to water. One pound of the wood afforded to Geiger two ounces of extract. "Guaiacum Wood is generally used in the form of raspings or turnings, which should be greenish-brown, containing few particles of a whitish color, and should acquire a dark-bluish-green color on the addition of nitric acid." *U. S.* 1890.

Uses.—Guaiacum wood ranks among the stimulant diaphoretics. It is said to have been introduced to the notice of European practitioners by the natives of Hispaniola soon after the discovery of America. It was used in Europe so early as 1508, and attained great celebrity as a remedy for *lues venerea*; but the general professional verdict is that it has no distinct influence in *syphilis*, nor yet in chronic *rheumatism* and *gout*, *scrofula*, or *cutaneous eruptions*, against which it was formerly much used. It is usually exhibited in decoction, and in combination with other medicines, as in the compound decoction of sarsaparilla.

Dose, thirty to sixty grains (2.0 to 3.9 Gm.).

Off. Prep.—Liquor Sarsæ Compositus Concentratus, *Br.*

GUAIACOL. U. S.

GUAIACOL

(gua'ī'a-cōl)

"One of the chief constituents [$C_6H_4(OH)(OCH_3)$ 1:2] of creosote, the product from beechwood-tar, obtained by collecting and purifying the fraction of creosote boiling between 200° and 205° C. (392° and 401° F.); or prepared synthetically from either catechol by methylating, or from ortho-anisidin by diazotizing and boiling. Guaiacol should be preserved in amber-colored bottles, protected from light." *U. S.*

Ortho-dioxybenzene-methyl-ester, Methyl-orthodioxymethyl-ester, Methyl-pyrocatechin, Catechol-monomethyl-ether; *Galacol*, *Fr. Cod.*; *Guajakol*, *Brenzcatechin*, *monomethyl-ester*, *G.*; *Guajacolo*, *It.*; *Guayacol*, *Sp.*

Preparation.—Guaiacol is the monomethyl ester of the ortho-dioxybenzene known as catechol (pyrocatechin), and can be readily made from this diatomic phenol by methylating with the aid of methyl-sulphuric acid. It is, however, largely obtained from beechwood creosote, of which it constitutes from 60 to 90 per cent. The separation of the diatomic phenols and phenol-ethers from monatomic phenols in a mixture like creosote, is effected in several ways. The compounds formed by baryta with the former are much less soluble than those with the latter, and this is also true of magnesia compounds. Another method is to rub up the creosote with potassium carbonate. Guaiacol and creosote combine to form

solid addition compounds, from which the other phenols are washed out with ether or petroleum benzin, when the crystalline mass is decomposed with water and the phenols separated.

Properties.—It is officially described as "a colorless, crystalline solid, melting at 28.5° C. (83.3° F.), or a colorless, refractive liquid, boiling at 205° C. (401° F.), having an agreeable aromatic odor. Specific gravity of liquid: 1.140 at 25° C. (77° F.). Soluble in 53 parts of water at 25° C. (77° F.), and in alcohol and ether in all proportions; soluble in acetic acid and in 1 part of glycerin. The addition of ferric chloride T.S. to an alcoholic solution of Guaiacol (1 in 100) causes an immediate blue color, changing to emerald green, and finally becoming yellowish. If 2 Cc. of Guaiacol be shaken with 4 Cc. of petroleum benzin, the mixture should separate, on standing, into two distinct layers. Turbidity or failure to separate into layers indicates the presence of impurities. One Cc. of Guaiacol should dissolve in 7 Cc. of sodium hydroxide T.S., when heated, and, on cooling, the mixture should congeal to a white mass. Coloration or failure to congeal indicates the presence of impurities. The white mass thus obtained should form a clear solution with 20 volumes of water (turbidity indicates *oily hydrocarbons*). One Cc. of Guaiacol, when added to 10 Cc. of concentrated sulphuric acid, should develop a pure yellowish color in the liquid (a reddish color indicating *creosote*)." *U. S.* S. Vreven recommended the following method for distinguishing between guaiacol and creosote: A drop of the liquid to be examined, 2 to 3 drops of ether, and 1 or 2 drops each of concentrated nitric and hydrochloric acids are well shaken together in a test tube. The mixture assumes at first a red-brown color, which is particularly evident in the ether layer; but upon spontaneous evaporation, well-formed needle-shaped crystals will separate out if guaiacol is present, the formation of these crystals being facilitated by occasional shaking, whereas in the presence of creosote oily globules only separate. While phenol gives a reaction similar to that of guaiacol, the crystals formed are easily distinguished from the needles produced by the latter. (*Zeit. Oest. Apoth. Ver.*, 1896, 711.)

Uses.—Locally, guaiacol is an irritant with some anæsthetic property. It is germicidal but, according to the experiments of Kuprianow, is distinctly less active than creosote or phenol. It is absorbed rapidly, not only from the alimentary canal but also through the skin. It is eliminated through the kidney, partly as a compound with sulphuric acid, partly as glycuronic acid and probably to some extent as guaiacol. Its general action, so far as known, resembles that of creosote but it affects temperature much more powerfully. The use of it as an antipyretic, in large doses, applied externally, which has been practised to some extent is, however, distinctly dangerous. Its

range of usefulness as an internal drug is that of creosote, as a substitute for which it has largely been used in *phthisis* and *bronchitis*. It has been considerably employed locally in *lupus*, *tubercular cystitis*, and in other forms of *surgical tuberculosis*. Inhalations of the aqueous solution (1 to 600) have been much used in *phthisis*.

Dose, five to ten minims (0.3 to 0.6 Cc.).

GUAIACOLIS CARBONAS. U. S.

GUAIACOL CARBONATE

(guaí'á-cū-lis cār'bō-nās)

"A guaiacol derivative [(C₆H₄(OCH₃)O)₂.C O], obtained by the action of carbonyl chloride upon sodium-guaiacolate." *U. S.*

Duotal; Carbonate de Gaïacol, *Fr.*; Guajacolkarbonat, Kohlensaure-Guajacylãther, *G.*; Carbonato de guayacol, *Sp.*

Properties.—It is officially described as in "white, crystalline powder, of neutral reaction, almost tasteless and odorless. Insoluble in water; soluble in 48 parts of alcohol, 1.5 parts of chloroform, and 13 parts of ether at 25° C. (77° F.); readily soluble in hot alcohol and benzene; slightly soluble in glycerin and fatty oils. When heated between 84° and 87° C. (183.2° and 188.6° F.), it fuses. Guaiacol Carbonate is at once decomposed when treated with alcoholic potassium hydroxide T.S., and from the solution so obtained guaiacol may be separated on the addition of an acid. An alcoholic solution of Guaiacol Carbonate should not yield a bluish-green color on the addition of ferric chloride T.S. (absence of *free guaiacol*)." *U. S.* It is known commercially as *duotal*.

Uses.—Guaiacol carbonate is much used as a substitute for guaiacol on account of its tastelessness and its lack of irritant properties. It is however much less active and less effective than is guaiacol both as a local and systemic drug. The experiments of W. Hesse indicate that when taken internally much of it passes through the alimentary canal unabsorbed.

Dose, fifteen to twenty grains (1 to 1.3 Gm.).

GUAIACUM. U. S. (Br.)

GUAIAC [Guaiaci Resina, Pharm. 1890, Guaiac Resin]

(guaí'á-cūm)

"The resin of the wood of *Guaiacum officinale* Linné, or of *Guaiacum sanctum* Linné (Fam. *Zygophyllaceæ*)." *U. S.* "The resin obtained from the stem of *Guaiacum officinale*, Linn., or *Guaiacum sanctum*, Linn." *Br.*

Guaiaci Resina, *Br.*; Gualacum; Gualacum Resin; Résine de Gayac, *Fr. Cod.*; Resina Guajaci, *P. G.*; Guajak, Guajakarz, *G.*; Resina de guajaco, *It.*; Resina de guayaco, *Sp.*

For a description of *Guaiacum officinale*, see *Guaiaci Lignum*, p. 602.

Guaiac is the concrete juice of this tree. It is obtained in several different modes. The most simple is by spontaneous exudation, or by incisions made into the trunk. Another method is by sawing the wood into billets about three feet long, boring them longitudinally with an auger, then placing one end of the billet on the fire, and receiving in a calabash the melted guaiac, which flows out through the hole at the opposite extremity. But the plan probably most frequently pursued is to boil the wood, in the state of chips or sawdust, in a solution of common salt, and skim off the substance which arises to the surface. Guaiac is brought to this market from the West Indies. It is usually in large irregular pieces of various sizes, in which small fragments of bark, sand, and other impurities are mixed with the genuine guaiac, so as to give to the mass a diversified appearance. Sometimes it is found in small roundish homogeneous portions, separate or agglutinated; sometimes in homogeneous masses, prepared by melting and straining the drug in its impure state. It is probable that the guaiac obtained from the billets in the manner above described is of uniform consistency.¹

Properties.—The masses are irregular or somewhat globular, of a glassy lustre and resinous fracture. They are of a deep greenish-brown or dark-olive color on their external surface, and internally wherever the air can penetrate. The predominant hue of those parts not exposed to the air is reddish brown or hyacinthine, diversified, however, with shades of various colors. The odor is feeble but fragrant, and is rendered stronger by heat. The taste, which is at first scarcely perceptible, becomes acrid after a short period, and a permanent sense of heat and pungency is left in the mouth and fauces. Guaiac is brittle, and when broken presents a shining glass-like surface, conchoidal or splintery, with smaller fragments more or less translucent. It is readily pulverized, and the powder, at first of a light-gray color, becomes green on exposure to the light. Its sp. gr. varies from 1.2 to 1.23. It softens in the mouth, and melts with a moderate heat. Water dissolves a small proportion of guaiac, not exceeding nine parts in 100, forming an infusion of a greenish-brown color and sweetish taste, which upon evaporation yields a brown substance soluble in hot water and alcohol, but scarcely so in ether. Alcohol takes up the whole, with the exception of impurities. The official requirements are as follows: "Not more than 15 percent. of Guaiac is insoluble in alcohol, and the alcoholic solution becomes blue on the addition of tincture of ferric chloride; acid number not less than 70 nor more than 80; ash not more than

4 percent. The filtrate obtained on macerating the powder with 4 or 5 times its weight of petroleum benzin should be colorless, and should not give a green color on the addition of an equal volume of solution (1 in 1000) of cupric acetate (absence of *rosin*)." *U. S.* The tincture is of a deep-brown color, is decomposed by water, and affords blue, green, and brown precipitates with the mineral acids. It is colored blue by nitric acid, by chlorine, and by tincture of ferric chloride, and usually by spirit of nitrous ether, and is similarly changed when treated successively by diluted hydrocyanic acid and solution of copper sulphate. Either in substance or tincture, guaiac gives a blue color to gluten and substances containing it, to mucilage of gum arabic, to milk, and to various freshly cut roots, as to the potato, carrot, and horseradish. It is soluble also in ether, alkaline solutions, and sulphuric acid. The solution in sulphuric acid is of a rich claret color, deposits, when diluted with water, a lilac precipitate, and, when heated, evolves charcoal. Exposed to air and light, guaiac absorbs oxygen and becomes green, and the change takes place rapidly in the sunshine. Tincture of guaiac has been used for the detection of blood stains, which it does by the blue color produced by it, when in contact with the red coloring matter of blood, in connection with some ozonized substance, especially hydrogen dioxide. (*Guy's Hospital Reports*, 3d ser., xiii. 432.) It may be used also to distinguish the blood of man and other mammals, in which the corpuscles are non-nucleated, from that of other classes, as birds, fishes, and reptiles, which have nucleated corpuscles. The method of R. M. Bertolet may sometimes be advantageously used in jury trials. A microscopic preparation, duly mounted, is carefully irrigated with a simple tincture of guaiac resin, and then, under glass, exposed to the action of a very small quantity of an ethereal solution of hydrogen dioxide. The mammalian corpuscles will exhibit a uniform blue coloration throughout, of different shades in the different corpuscles, while, if the blood corpuscle is nucleated, the nucleus is seen as a well defined and deep blue body, with a delicate violet colored medium around it. (*Am. J. M. S.*, Jan. 1874.)

Lücker (*Proc. A. Ph. A.*, 1894, 953), having reinvestigated guaiacum, stated that it consists chiefly of three acids,—viz., *guaiacic*, $C_{20}H_{24}O_4$, occurring in crystals melting at $86^\circ C$; *guaiaconic*, $C_{20}H_{24}O_5$, an amorphous body melting at from 81° to $83^\circ C$; and *guaiacinic*, $C_{21}H_{22}O_7$. He considers all three of them to be probably condensation products from tiglic aldehyde with creosol and guaiacol. Döbner has also determined that these three acids form a series of hydroxyl containing acids which may be represented by the formulas: $C_{20}H_{23}O_5(OH)$, $C_{20}H_{22}O_5(OH)_2$ and $C_{21}H_{21}O_7(OH)_3$. (Tschorich, *Harze und Harzbehälter*, 1900, p. 300.) *Guaiac yellow*, the coloring matter of guaiac resin, was first observed by Pelletier.

¹ Under the name of *Resina Guaiaci Peruviana Aromatica* there is a substance known in European commerce which probably has no relation to guaiac. For a summary of our knowledge concerning it, see *A. J. P.*, 1877, p. 18.

It crystallizes in pale yellow quadratic octahedra having a bitter taste, but is not a glucoside. Guaiac resin also yields interesting products on dry distillation. First, according to Hlasiwetz, is obtained *guaiacene*, C_8H_8O , at

$118^\circ C.$, next *guaiacol*, C_8H_8 $\left\{ \begin{array}{l} OCH_3 \\ OH \end{array} \right.$, being the

methyl ether of pyrocatechin, at 205° to $210^\circ C.$, and with it *kreosol*, $C_8H_8(CH_3)_2OH$, and finally *pyroguaiacin*, $C_{10}H_{14}O_3$ (according to Wiesner, $C_{12}H_{18}O_3$), in pearly scales, melting at $180^\circ C.$ According to Lieben and Zeisel (*Ber. d. Chem. Ges.*, xiv. p. 932), guaiacene is the aldehyde of tiglic acid, $C_8H_8O_2$, and can be made synthetically from a mixture of acetaldehyde and propionaldehyde. When distilled with zinc dust there is obtained *creosol* (50 per cent. in the case of resin purified by alcohol) and 30 per cent. of a mixture of *toluene*, *meta*- and *para*-xylene, with a little *pseudocumene* and *guaion*, $C_{12}H_{12}$. (Bötsch, *M. Chem.*, 1880, 615.)

Saponin has been found by E. Paetzold in the bark, the wood, and the natural resin of guaiacum. (*Bull. des Sciences Pharm.*, iii. 407.) According to the experiments of W. Frieboes (*In. Dis.*, Rostock, 1903), this saponin (1 to 1000) forms a frothing solution which is persistent, is an excellent emulsifier, has the power to maintain in solution large proportions of sparingly soluble substances and is innocuous and non-irritant.

The mineral acids are incompatible with the solutions of guaiac.

Adulterations.—This drug is sometimes adulterated with the rosin of the pine. The fraud may be detected by the terebinthinate odor exhaled when the sophisticated guaiac is thrown upon burning coals, as well as by its partial solubility in hot oil of turpentine. This liquid dissolves rosin, but leaves pure guaiac untouched. Amber is said to be another adulterant. Nitric acid affords an excellent test of guaiac. If paper moistened with the tincture be exposed to the fumes of this acid, it speedily becomes blue. Purgotti proposed guaiac resin as a test for copper. (See *A. J. P.*, June, 1880.)

Uses.—Guaiac is stimulant and alterative. If given to a patient when covered warm in bed, especially if accompanied with opium and ipecac or the antimonials, and assisted by warm drinks, it often excites profuse perspiration, and hence it has been usually ranked among the diaphoretics. In large doses it purges, and it has been especially commended as a laxative in chronic rheumatism, and it is thought by some practitioners to be possessed of emmenagogue powers. It has been given with asserted advantage in *chronic rheumatism*, *gouty affections*, *secondary syphilis*, *scrofulous diseases*, and *cutaneous eruptions*. The medicine is given in substance or tincture. The dose of the powder is from ten to thirty grains (0.65 to 2.0 Gm.), which may be exhibited in pill or bolus, in the shape of an emulsion

formed with gum arabic, sugar, and water, or as a syrup.¹ An objection to the form of powder is that it quickly aggregates. Guaiac is sometimes administered in combination with alkalies, with which it readily unites. Several European Pharmacopœias direct a *soap of guaiac*, under the name of *sapo guaiacinus*, to be prepared by diluting solution of potassium hydroxide with twice its weight of water, boiling lightly, then adding guaiac gradually, with continued agitation, so long as it continues to be dissolved, and finally filtering, which was followed by evaporating to the pilular consistence.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

GUARANA. U. S.

GUARANA

(guã-rã'na)

"A dried paste consisting chiefly of the crushed seeds of *Paullinia Cupana* Kunth (Fam. *Sapindaceæ*), yielding, when assayed by the process given below, not less than 3.5 per cent. of its alkaloidal principles." U. S.

Paullinia, Brazilian Cocoa, Guarana Bread; *Guarana*, Fr. Cod.; *Pasta Guaranae*; *Guarana*, G., It.; *Paulinia*, Guarana, Sp.

There are described of the genus *Paullinia* 121 species, all of them confined in their geographical range to tropical and subtropical South America, except one, which has strayed to Eastern and Western Africa, and two others which are found in Mexico and in the gardens of the Sandwich Islands. The name of the genus was given in honor of Christ. Fred. Paullini, a German medico-botanical writer, who died in 1712.

P. sorbilis, Martius, *Reise in Brasil*, vol. iii. 1098; *B. & T.* 67.—*Guarana úva*.—This woody climber grows in the northern and western provinces of Brazil, ripening its seeds in October and November. The leaves are alternate, on long stalks, impari-pinnate, with five oblong, oval, coarsely irregularly sinuate-dentate leaflets, five to six inches long by two to three broad, contracted into a shortly attenuated blunt point. The flowers are arranged in axillary, spicate panicles, four inches or more in length. The fruit is about the size of a grape, ovoid or pyriform, on a short peduncle, with a short

¹*Syrup of Guaiac*. T. C. Craig. (*A. J. P.*, July, 1880).—Powd. Guaiac Resin, 640 grains; Caustic Potassa, 58 grains; White Sugar, lbj (av.); Water, q. s. Dissolve the Potassa in 8 fluidounces of water; moisten the Guaiac with this solution; pack it in a percolator, and gradually pour on the remainder of the solution; when this ceases dropping, add sufficient water to make the percolate measure 8 fluidounces; add the sugar, and dissolve.

strong beak, glabrous, with six longitudinal ribs. The three-valved pericarp is thin, tough, and strongly hairy within.

Preparation and Properties.—The seeds, which look like small horse-chestnuts, are contained in a three-celled, three-valved, coriaceous capsule, are lenticular and almost thorny, and invested with a flesh-colored arillus, which is easily separable when dry. Guarana is made exclusively by the Guarani, a tribe of South America Indians, and probably varies in the details of its preparation, as it certainly does in appearance and quality. The drug appears to be produced almost exclusively from plants cultivated in the region of the lower Madeira and southward. After the seeds are shelled and thoroughly washed they are roasted for about six hours, and their external papery shells are then removed by placing them in sacks and beating them with clubs; or, after the seeds have been broken in a mortar, the coarse powder is mixed with a little water, and then kneaded into a paste, which is shaped into cylindrical or globular masses. According to Rusby, the common belief that at this stage various foreign bodies are added to the paste is incorrect. The masses are dried, sometimes in the sun, or more usually by the heat of a slow fire so arranged as to avoid smoke. When finished, the masses are of a reddish-brown color, rugose on the surface, very hard, with an irregular fracture, and of a marbled appearance when broken, due to the fragments of the seeds and their black testa embedded in the mass.

Properties.—It is officially described as follows: "Usually in cylindrical sticks, about 3 to 5 Cm. in diameter, hard and heavy, dark reddish-brown; fracture uneven, often fissured in the centre, pale reddish-brown, showing numerous coarse fragments of seeds and their blackish-brown integuments; odor slight; taste astringent, somewhat smoky and unpleasantly bitter, then sweetish." *U. S.*

Guarana is of a somewhat astringent and bitterish taste, and in this, as well as in its odor, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. It is also partly soluble in alcohol. Martius found in it a crystallizable principle, which he named *guaranine*, but which has been proved by Berthelot and Dechastelus to be identical with *caffeine*. Alexander Bennett, in an elaborate series of physiological experiments, has confirmed this identity.¹ The discovery of caffeine in plants belonging to distinct natural families, namely, the coffee and tea plants, the Paraguay tea, and the Paullinia, is a highly interesting result of recent chemical investigations. It is said to be more abundant in the Paullinia than in either of the other vegetables, 5.07 per cent. having been found by Stenhouse in Paullinia, while he obtained only 2.13 per

cent. from good black tea, 1.00 from coffee, and 1.2 from Paraguay tea. (*P. J.*, xvi. 213.) According to Berthelot and Dechastelus, it exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients the seeds contain free tannic acid, gum, albumen, starch, and a greenish fixed oil. (*J. P. C.*, xxvi. 514.) For a method of preparing guaranine, see *J. P. C.*, 4e sér., xviii. 224.

RocheFontaine and Gusset prepared guaranine by mixing one part of calcined magnesia with five parts of powdered guarana, moistening with water, and, after standing twenty-four hours, exhausting the mass with boiling chloroform, evaporating the chloroform, treating the residue with boiling water, filtering, and evaporating over sulphuric acid. (*A. J. P.*, 1886, p. 248.) F. V. Greene (United States Navy) prefers a process for obtaining caffeine from guarana similar to one proposed by Wayne for its extraction from tea and coffee. The details of the method are as follows: The powdered guarana is intimately mixed with three times its weight of finely divided litharge, and the mixture boiled in distilled water, until, on allowing the temperature to fall below the boiling point, the insoluble portion is found to subside rapidly, leaving the supernatant liquid clear and without color. When cool, the clear liquid is filtered, and the precipitate is transferred to the filter and washed with boiling water, the washing to be continued as long as yellowish precipitates are produced with either phosphomolybdic acid solution, auric or platonic chloride. A stream of hydrogen sulphide gas is now passed through the filtrate, and the lead sulphide thus formed separated by filtration. The solution is evaporated on a water bath to expel the excess of hydrogen sulphide, filtered to remove a trace of sulphur, finally evaporated to the crystallizing point, and the caffeine, which crystallizes out on cooling, removed from the mother liquor and pressed between folds of bibulous paper. After being thus treated, the crystals will be found to be perfectly white. A shorter process for the assay of guarana is given by C. H. LaWall. (*A. J. P.*, 1897, 350.) It is as follows:

Five Gm. of the drug and 5 Cc. of 16 per cent. ammonia water are placed in a separatory funnel. After allowing the mixture to stand for thirty minutes, the alkaloid is shaken out with chloroform, using three portions of 20 Cc. each. F. V. Greene has shown that the tannic acid from guarana has different properties from that found in other plants, and proposes to call it *paullinitannic acid*. (*A. J. P.*, 1877, 390.) Fournier has found in paullinia, besides caffeine tannate, the following principles: gum, starch, an acid green fixed oil, a concrete volatile oil, an aromatic liquid volatile oil soluble in water with a little alcohol,

¹ This identity has been denied by T. J. Mays. (See H. C. Wood's *Therapeutics*.)

another liquid volatile oil scarcely soluble in water, a peculiar principle not precisely determined, and tannic acid. (*J. P. C.*, Avril, 1861, 291.) E. R. Squibb examined commercial guarana, and obtained 4.38 per cent. of alkaloid from good specimens. On account of the uncertainty of the composition of guarana, he recommended physicians to prescribe fluidextract of green coffee in its place. (*See Ephem.*, 1884, 612.)

Assay. U. S. (8th Rev.).—"Guarana, in No. 60 powder, *six grammes*; Chloroform, Ether, Ammonia Water, Normal Sulphuric Acid V.S., Distilled Water, each, *a sufficient quantity*. Introduce the Guarana into an Erlenmeyer flask, and pour upon it 120 Cc. of chloroform and 6 Cc. of ammonia water, and insert the stopper securely. Shake the flask at intervals for half an hour, and allow it to stand for four hours. Filter a sufficient quantity of the liquid into a measuring cylinder until 100 Cc. (representing 5 Gm. of Guarana) have been obtained, then transfer the filtrate to a flask, and distil off all of the chloroform by means of a water-bath. Dissolve the alkaloidal residue in a mixture of 2 Cc. of normal sulphuric acid V.S. and 20 Cc. of warm distilled water. Allow the liquid to cool, and filter it into a separator, rinse the flask and filter with several small portions of distilled water, add 20 Cc. of chloroform and 2 Cc. of ammonia water to the separator, and shake it for one minute. Draw off the chloroform into a tared flask and repeat the extraction with two portions of 10 Cc. each of chloroform. Distil off the chloroform from the combined liquids, and when the residue is dry, add 2 Cc. of ether and evaporate on a water-bath very carefully to avoid decrepitation; continue the heating until the weight of the residue after cooling remains constant. This weight multiplied by 20 will give the percentage of the alkaloidal principles contained in the Guarana." U. S.

Uses.—The effects of guarana upon the system are chiefly those of its alkaloid, although it contains enough tannin to have an appreciable influence. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink, prepared by scraping it, and suspending the powder in sweetened water, precisely as other nations use teas, coffees, etc. It is also considered by the Indians useful in the prevention and cure of bowel complaints. Gavrelle, who was at one time physician to Dom Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it some years since in France. It is now used in medicine almost exclusively to give relief during the paroxysm of *migraine*, and in atonic *chronic diarrhœa*, taken three or four times a day.

Dose. of the powder, twenty to sixty grains (1.3 to 3.9 Gm.); of the fluidextract, twenty to sixty minims (1.3 to 3.75 Cc.).

HÆMATOXYLON. U. S. (Br.)

HÆMATOXYLON [Logwood]

(hæ-mă-tôx'yl-on)

"The heart-wood of *Hæmatoxylon campechianum* Linné (Fam. *Leguminosæ*)." U. S.
 "The heart-wood of *Hæmatoxylon campechianum*, Linn." Br.

Hæmatoxylil Lignum, Br.; Lignum Campechianum, Lignum Cœruleum; Bois de Campêche ou Bois d'Inde, *Fr. Cod.*; Bois de Sang, *Fr.*; Blauholz, Campecheholz, Blutholz, Kampeschenholz, *G.*

Hæmatoxylon campechianum, Willd., *Sp. Plant.* ii. 547; Woodv., *Med. Bot.* 455, t. 163; Carson, *Illust. of Med. Bot.*, i. 33, pl. 25.—This is a tree of middle size, usually not more than twenty-four feet high, though, under favorable circumstances, it sometimes rises forty or fifty feet. The trunk, seldom exceeding twenty inches in diameter, is often very crooked, and is covered with a dark rough bark. The branches are also crooked, with numerous smaller ramifications, which are beset with sharp spines. The sap-wood is yellowish, but the interior layers are of a deep-red color. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly obovate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx and lemon-yellow petals. They exhale an agreeable odor, said to resemble that of the jonquil.

The tree is a native of Campeche, the shores of Honduras Bay, and other parts of tropical America, and has become naturalized in Jamaica. The wood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs deprived of the sap-wood and having a blackish-brown color externally. According to Louis Siebold, the ground or chipped logwood of commerce is unfit for use as a medicinal agent, because it has been prepared as a dyestuff by being exposed in large moist heaps until its hæmatoxylin has been converted by oxidation into hæmatein. As a coloring agent, for commercial purposes, this fermented logwood, according to Siebold, is much superior to the natural wood. An inferior variety of logwood which contains little or no hæmatoxylin, but a pure yellowish-gray dye is that known as *bastard logwood*. According to the researches of E. S. Earl this bastard logwood is produced by a variety of the species, which, when growing, cannot be distinguished from the ordinary form. (*B. D. A. J.*, i. 31.)

Properties.—Logwood is hard, compact, heavy, of a deep-red color, becoming purplish black by exposure, internally brown-red, and marked with irregular, concentric circles, splitting irregularly, of a slight peculiar odor, and a sweet, somewhat astringent taste. Logwood is officially described as "usually in small chips, reddish-brown, the freshly cut surface

dark yellowish-red; on transverse section the wood showing medullary rays which are four cells wide; odor faint, agreeable; taste sweetish, astringent. Hæmatoxylon imparts to water containing a little acid a yellowish color, which is changed to purple or violet-red by alkalis. When the surface has a greenish metallic lustre, the wood has undergone fermentation and should be rejected." *U. S.* It imparts its color to water and alcohol. Its solution affords precipitates with sulphuric, nitric, hydrochloric, and acetic acids, alum, copper sulphate, lead acetate, and ferrous sulphate, striking a bluish-black color with the last mentioned salt. Precipitates are also produced with it by lime water and gelatin. Chevreul found in logwood a volatile oil, an oleaginous or resinous matter, a brown substance the solution of which is precipitated by gelatin (*tannin*), another brown substance soluble in alcohol but insoluble in water or ether, a nitrogenous substance resembling gluten, free acetic acid, various salts, and a peculiar principle called *hæmatoxylin* or *hematin*, on which the coloring properties of the wood depend. This is obtained by digesting the aqueous extract in alcohol, evaporating the tincture until it thickens, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hæmatoxylin is deposited in crystals, which may be purified by washing with alcohol and drying. Thus procured, the crystals are shining, of a yellowish-rose color, bitterish, acid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. According to Erdmann, who obtained hæmatoxylin by the process of Chevreul, substituting ether for alcohol, its crystals, when quite pure, are colorless, without a tinge of redness; its taste is sweet, like that of licorice, without bitterness or astringency; and it is not of itself a coloring substance, but affords beautiful red, blue, and purple colors, by the joint action of an alkaline base and the oxygen of the air. He obtained from logwood 9 to 12 per cent. of crystallized hæmatoxylin, to which he gave the formula $C_{16}H_{14}O_6$. It crystallizes with 1 or with 3 molecules of water, and is readily soluble in hot water or alcohol, but sparingly in cold water or in ether. (*J. Pr. Chem.*, 36, p. 205.) By the combined action of ammonia and oxygen dark violet crystalline scales of *hematein*, $C_{16}H_{12}O_6 + 3H_2O$, are produced. They show a fine green hue, which is also very commonly observable on the surface of the logwood chips of commerce. Hematein may again be transformed into hæmatoxylin by means of nascent hydrogen or of sulphurous acid. Commercial extract of logwood extracted from the wood by boiling water contains both hæmatoxylin and hematein. Hæmatoxylin, in alcoholic solution, is used as an indicator in the *U. S. P.* (8th Rev.). (See Test-solution No. 127, PART III.)

Uses.—Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of bowels which is apt to succeed *cholera infantum*. It is also occasionally used with advantage in ordinary *chronic diarrhœa* and *chronic dysentery*. The only *U. S.* official preparation is the extract. *Hæmatoxylin* was found by Combemale (*B. M. N.*, xxxiii. 1894) to be very feebly antiseptic, but capable in large doses of producing fatal gastro-enteritis in the lower animals.

Dose, from ten to twenty grains (0.65 to 1.3 Gm.).

HAMAMELIDIS CORTEX. *U. S.*, *Br.*

HAMAMELIS BARK [Witchhazel Bark]

(hām-ā-mēl'ī-dis cūr'tēx)

"The bark and twigs of *Hamamelis virginiana* Linné (Fam. *Hamamelidaceæ*)."
"The dried bark of *Hamamelis virginiana*, Linné." *Br.*

Witchhazel, Spotted Hazel, Snapping Hazel, Winter-bloom; Ecorce de Hamamelis, *Fr. Cod.*; Hamamelis, Zauberhasel, *G.*; Hamamelis, *Sp.*

H. virginiana, L.—*Witchhazel* is an indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and often on the banks of streams. It is the only species of the genus found in Eastern North America, and is specifically characterized by its leaves being obovate or oval, wavy-toothed, and somewhat downy when young. The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazelnut. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue until the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazelnut, ripens in the following autumn, and is often mingled on the same plant with the new blossoms.

Properties.—The bark occurs "in irregularly quilled or bent pieces, 1 to 2 Mm. thick; outer surface grayish-brown, with numerous lenticels, or reddish-brown, with short transverse ridges or scars, or somewhat scaly in older bark; the thin, corky layer easily removed from the pale cinnamon-colored middle bark; inner surface pale cinnamon-colored, or sometimes yellowish, smooth, or finely striate; fracture of young bark short, of old bark tough in the bast layer; odor faint; taste astringent, somewhat bitter and pungent. Twigs flexible and tough, of irregular length, not more than 6 Mm. in diameter, branching, or bearing nodes at intervals of 2 to 5 Cm.; externally varying from yellowish-brown to deep purplish-brown, lightly longitudinally wrinkled, and having scattered

small circular whitish or pale lenticels; bark occupying about one-fifth of the radius; wood greenish-white, lightly radiate, and exhibiting one to three annual rings; pith centric, small." *U. S.* In the *Br. Pharm.* it is characterized as "usually in curved pieces about one-sixteenth of an inch (one and a half millimetres) thick, and varying from two to eight inches (one-half to two decimetres) in length, sometimes covered with a silvery-gray or dark-gray scaly cork marked with transverse lenticels, but frequently freed from the cork, and then exhibiting a nearly smooth reddish brown outer surface. The inner surface is pale reddish pink in color, and finely striated longitudinally; the fracture is laminated and coarsely fibrous. The bark has an astringent taste, but no marked odor. The transverse section exhibits a complete ring of sclerenchymatous cells and numerous tangentially elongated groups of bast fibres." *Br.*

Walter B. Cheney examined witchhazel bark, and found tannin, resin, extractive, but no indication of an alkaloid or other crystalline principle. (*A. J. P.*, 1886, p. 418.) It contains a trace of volatile oil, however. John Marshall of the University of Pennsylvania, also found that hamamelis root contains tannic acid and a trace of volatile oil, but no other active substance. (*T. G.*, ii. 295.)

Uses.—The bark of the witchhazel is said to have first attracted attention on account of its use by the North American Indians as a sedative application to external inflammations. It was many years ago strongly recommended by James Fountain and N. S. Davis (*N. Y. M. J.*, x. 208; *Trans. Amer. Med. Assoc.*, i. 350) in hemorrhage of the lungs and stomach. Fountain also used with alleged great advantage, an ointment prepared from lard and the decoction of equal parts of hamamelis, white oak bark, and apple tree bark. Of late years professional attention has been very strongly directed to the remedy on account of the enormous sale of a much vaunted proprietary remedy said to be made by distilling the bark with very dilute alcohol (six per cent.), and used externally for sprains and bruises, and internally for most of the diseases to which flesh is heir. The pecuniary success of this remedy probably has depended in very small part upon the virtues of the witchhazel, which seems to possess no active physiological properties. At least we have injected a very concentrated distillate in large quantities into frogs and into mammals without perceiving any more effects than would be produced by the injection of similar quantities of distilled water, and Guy, in Paris, has reached similar conclusions. The fluidextract of the drug has been used as a remedy in various forms of venous dilatation and engorgement. It was very strongly recommended by John H. Musser in varicose veins (*P. M. T.*, vol. xiii.), and has been used by some practitioners with good results in cases of hemorrhoids, but has failed to yield in other hands

corresponding advantage. (See *B. M. S. J.*, April 16, May, 1885; also *B. G. T.*, vol. evi.) The dose of the fluidextract given by Musser was a teaspoonful (3.75 Cc.) four times a day. It may, however, be given in double the quantity with impunity and probably in such doses is an advantageous astringent.

Dose, of leaves or of bark, thirty grains (2 Gm.).

HEDEOMA. U. S.

HEDEOMA [*Pennyroyal*]

(hēd-ə-ō'mə)

"The dried leaves and flowering tops of *Hedeoma pulegioides* (Linné) Persoon (*Fam. Labiatae*)." *U. S.*

American or Mock Pennyroyal, Squawmint, Mosquito Plant; Herbe de Pouillot américaine, Fr.; Amerikanischer Polei, G.

This plant is entirely distinct from *Mentha Pulegium*, or European pennyroyal. It is probable that various other species of the genus are used in the localities in which they grow. Thus, *H. piperita*, Benthams, is said to be used in Mexico as a substitute for peppermint, and *H. thymoides*, Gray, in Texas as an aromatic diaphoretic.

Hedeoma pulegioides (L.), Pers. (1807); *Cumula pulegioides*, L. (1762); *Melissa pulegioides*, L. (1753).—This is an indigenous annual plant, from nine to fifteen inches high, with a small, branching, fibrous, yellowish root, and a pubescent, quadrangular stem, which

sends off numerous slender erect branches. The leaves are opposite, having short petioles, about half an inch long, oblong-lanceolate or oval, nearly acute, attenuated at the base, remotely serrate, rough or pubescent, and prominently veined and glandular on the under surface. The flowers are very small, pale blue, supported on short peduncles, and arranged in axillary whorls along the whole length of the branches. They have a tubular-ovoid, two-lipped and five-toothed calyx, and a pale blue, spotted, two-lipped corolla, containing two sterile and two fertile exerted stamens. The plant is common in the Eastern and Middle Western United States, preferring dry grounds. Hedeoma is officially described as "branchlets quadrangular, with numerous spreading hairs; leaves opposite, short-petioled, oblong, 15 to 35 Mm. long, thin, obtuse, obscurely serrate, glandular-hairy beneath; flowers in axillary fascicles, with a tubular-ovoid, bilabiate and 5-toothed calyx, and a pale blue, spotted, bilabiate corolla containing two sterile and two fertile, exerted stamens; odor strong, somewhat mint-like; taste aromatic and pungent." *U. S.* The activity of hedeoma depends upon a volatile oil. (See *Oleum Hedeomæ*.)

Uses.—American pennyroyal is a gently stimulant aromatic, and may be given in fulgent colic and sick stomach, or to qualify the action of other medicines. Like most of the aromatic herbs, it possesses the property, when administered in warm infusion, of promoting perspiration, and of exciting the menstrual flux when the system is predisposed to the effort. A large draught of the warm tea is in popular practice often given at bedtime, in recent cases of suppression of the menses, the feet having been previously bathed in warm water.

Dose, two drachms (7.7 Gm.).

HEMIDESMI RADIX. Br.

HEMIDESMUS ROOT

(hēm-j-dēs'mī rā'dīx)

"The dried root of *Hemidesmus indicus*, *R. Br.*"

Indian Sarsaparilla; Nunnari; Racine de Hemidesmus, *Fr.*; Hemidesmus-Wurzel, *G.*

Hemidesmus indicus (Willd.), *R. Br.*, Engler and Prantl; *H. indicus*, *R. Br.*, *Hort. Kew.* ii. 75; Lindley, *Flor. Med.* p. 543.—*Periploca indica*, Willd., *Sp. Plant.* i. 1251; *Fam. Asclepiadaceæ*.—This is a climbing plant, with twining, woody, slender stems, and opposite petiolate leaves, which are entire, smooth, shining, and of a firm consistence. The leaves vary much in size and shape, some being linear and acute, others broad-lanceolate, and others again oval or ovate. The flowers are small, green on the outside, purple within, and disposed in axillary racemes. The calyx is five-parted, with acute divisions; the

corolla flat, with oblong, pointed divisions. The fruit consists of two long, slender, spreading folioles.

This plant is common over the whole peninsula of Hindostan. The official portion is the root, which has long been used in India as a substitute for sarsaparilla. It is long, rarely more than one-quarter of an inch in diameter, rigid, tortuous, cylindrical, and little branched, consisting of a ligneous centre, and a brownish, corky bark, marked with longitudinal furrows and transverse fissures. The odor is aromatic, the taste sweetish. On one side of the root the cork is frequently separated from and raised above the cortex, and is transversely fissured. The transverse section exhibits numerous laticiferous cells in the cortex. For details of microscopic structure, see *P. J.*, 1872, 62. Garden obtained from hemidesmus a peculiar, volatilizable acid principle, which he named *smilasperic acid*, under the erroneous impression that the root was derived from *Smilax aspera*. Pereira proposed to call it *hemidesmic acid*. Scott also obtained a stearopten by distillation with water, presumably the same material. It has not been further investigated.

Uses.—Hemidesmus root is said to be tonic, diuretic, and alterative. It was introduced into Great Britain from India, and was employed for some time under the name of *Smilax aspera*. It is used for the same purposes as sarsaparilla, and in some instances it is said to have proved successful in *syphilis* when that medicine had failed, but it cannot be relied upon. The native practitioners in India are said to employ it in nephritic complaints, and in the sore mouth of children. It is used in the form of infusion or decoction, made in the proportion of two ounces of the root to a pint of water. A pint may be given in wineglassful doses in the course of the day.

Off. Prep.—Syrupus Hemidesmi, *Br.*

HEXAMETHYLENAMINA. U. S.

HEXAMETHYLENAMINE

(hěx-q-mē-thyl-ēn-q-mī'nə)

$C_6H_{12}N_4 = 139.18$

"A condensation product [Hexamethylenetetramine, $(CH_2)_6N_4$], obtained by the action of ammonia upon formaldehyde. It should be kept in well-stoppered bottles." *U. S.*

Urotropine, Urotropin, Cystogen, Formin, Aminoforn.

The full name of this compound is hexamethylenetetramine, which was originally used by Nicolaier; the Latin title was shortened upon its admission to the U. S. P. (8th Rev.) to *Hexamethylenamina*.

Preparation.—Hexamethylenamine may be made by the gradual addition of 70 parts of stronger ammonia water to 100 parts of a forty per cent. solution of formaldehyde which must be kept well cooled. The ammonia water

must be added carefully in small quantities until in slight excess, which is indicated by its odor remaining after the liquid has stood several hours; then 10 parts of ammonia water are added and the solution allowed to stand until crystallization is completed. The hexamethylenamine is purified by treatment with animal charcoal and recrystallization.

Properties.—It is officially described as in "colorless, lustrous, odorless crystals, having, when in aqueous solution, an alkaline reaction upon red litmus paper. Soluble in about 1.5 parts of water, 10 parts of alcohol, and in 228 parts of ether at 25° C. (77° F.); in 1.5 parts of water at 100° C. (212° F.), and in about 8 parts of hot alcohol. When heated to 263° C. (505.4° F.) it sublimes without melting and with partial decomposition. If 0.1 Gm. of Hexamethylenamine be mixed with 0.1 Gm. of salicylic acid and 5 Cc. of sulphuric acid, and then heated moderately, a carmine-red color should be produced. If an aqueous solution of Hexamethylenamine (1 in 10) be heated with diluted sulphuric acid, it is decomposed with the liberation of formaldehyde (recognized by its odor or by its darkening paper moistened with silver ammonium nitrate T.S.). If an aqueous solution (1 in 10) be heated with diluted sulphuric acid and then supersaturated with solution of sodium hydroxide, ammonia is liberated. If to an aqueous solution (1 in 10) tannic acid T.S. be added, a precipitate is formed. If mercuric chloride T.S. be added to an aqueous solution (1 in 10), a precipitate is produced which on standing forms crystalline needles." *U. S.*¹

Uses.—Hexamethylenamine is distinctly but not violently a local irritant: taken internally it is eliminated with great rapidity generally unchanged, its presence often being detected in the urine in one half hour, and as long as 24 hours, after its ingestion. The former belief that it was largely decomposed with the liberation of formaldehyde in the kidney is probably not correct, although frequently formaldehyde may be detected in the urine after its ingestion. The change appears to occur after the excretion from the kidney, and probably takes place only when there is an excess of acid in the urine. Suder having demonstrated that hexamethylenamine mixed outside of the body with acid urine undergoes decomposition and fails to do so when the urine is alkaline shows the necessity, when hexamethylenamine is exhibited, that care should be taken to maintain the acidity

of the urine. Upon the general system hexamethylenamine exerts no perceptible influence. When given in overdose it causes irritation of the kidney with burning pain in the bladder and urethra, and, it may be, an acute nephritis. A measles-like rash with much itching has been noticed after its continuous use. Hexamethylenamine probably is itself possessed of marked bactericidal powers, and it probably achieves good in urinary diseases by virtue of its own inherent properties. Originally suggested as a uric acid solvent, clinical experience has shown that it is about equivalent to piperazine in this respect and really is of no value for the solution of formed *renal calculi*. It is of great value in *pyelitis*, *cystitis*, also in *phosphaturia*. In *gonorrhoea* it seems to be of no service. It is also stated by various authorities to be a very serviceable intestinal antiseptic. Hexamethylenamine should be administered in at least a half a pint of water.

Dose, five to fifteen grains (0.32 to 1.0 Gm.), three to six times a day.

HIRUDO. Br.

LEECHES

(hî-rû'dô)

"1. *Sanguisuga medicinalis*, *Savigny*, the Speckled Leech; and 2. *Sanguisuga officinalis*, *Savigny*, the Green Leech." *Br.*

Sangsue médicinale, *Fr. Cod.*; *Hirudines*, *P. G.*; *Blutegel*, *G.*; *Sanguisuga*, *Mignatta*, *It.*; *Sanguijuela*, *Sp.*

HIRUDO.—Class 1, Annelides. Order 3, *Abranchiata*. Family 2, *Asetigeræ*. Cuyrier.

The leech belongs to that class of invertebrated articulated animals called *Annelides*. This class contains the worms with red blood, having soft retractile bodies composed of numerous segments or rings, breathing generally by means of branchiæ, with a nervous system consisting in a double knotted cord, destitute of feet, and supplying their place by the contractile power of their segments or rings. The third order of this class—*Abranchiata*—comprehends those worms which have no apparent external organ of respiration. This order is again divided into two families, to the second of which—the *Asetigeræ*, or those not having setæ to enable them to crawl—the leech belongs.

It is an aquatic worm with a flattened body, tapering towards each end, and terminating in circular flattened disks, the hinder one being the larger of the two. It swims with a vertical undulating motion, and moves when out of the water by means of these disks or suckers, fastening itself first by one and then by the other, and alternately stretching out and contracting its body. The mouth is placed in the centre of the anterior disk, and is furnished with three cartilaginous jaws at the entrance of the alimentary canal. These jaws are lined at their edges with fine sharp teeth, and

¹ Hexamethylenamine may be detected in the urine by adding bromine water, which precipitates the orange yellow hexamethylenamine dibromide. Citron's test is as follows (*M. H. S. A.*, 1898): Acidify the urine slightly, boil in a flask or test tube, in the mouth of which has been placed a cotton plug soaked with solution of resorcinol in sodium hydroxide, when a brilliant red color will develop. This test depends on the liberation of formaldehyde due to the decomposition of the hexamethylenamine in acid solution. The reaction with the resorcinol is the same as is described in the test for methyl alcohol (see *Alcohol*, p. 105).

meet so as to make a triangular incision in the flesh. The head is furnished with small raised points, supposed by some to be eyes. Respiration is carried on through small apertures ranged along the inferior surface. The nervous system consists of a cord extending the whole length, furnished with numerous ganglions. The intestinal canal is straight, and terminates in the anus, near the posterior disk. Leeches are hermaphrodite, and mutually impregnate each other. They are oviparous; and the eggs, varying from six to fifteen, are contained in a sort of spongy, slimy cocoon, from half an inch to an inch in diameter. These are deposited near the edge of the water, and hatched by the heat of the sun. The leech is torpid during the winter, and casts off from time to time a thick slimy coating from its skin. It can live a considerable time in sphagnum moss or in moistened earth, and is frequently transported in this manner to great distances without injury.

Savigny has divided the genus *Hirudo* of Linnæus into several genera. The true leech is the *Sanguisuga* of this author, and is characterized by its three lenticular jaws, each armed with two rows of teeth, and by having ten ocular points. Several species are used for medicinal purposes, of which the most common are the gray and the green leech of Europe, both of which are varieties of the *Hirudo medicinalis* of Linnæus, and the *Hirudo decora* of this country.

1. *Hirudo medicinalis*, Linn., Ed. Gmel. i. 3095. The green leech—*Sanguisuga officinalis*, Savigny, Mon. Hir. p. 112, t. 5, f. 1. The gray leech—*Sanguisuga medicinalis*, Savigny, Mon. Hir. p. 114, t. 5, f. 2.—Many of the best zoologists regard the *Sanguisuga officinalis* and *S. medicinalis* of Savigny as mere varieties. They are both marked with six longitudinal dorsal ferruginous stripes, the four lateral ones being interrupted or tessellated with black spots. The color of the black varies from a blackish to a grayish green. The belly in the first variety is of a yellowish-green color, free from spots, and bordered with longitudinal black stripes. In the second it is of a green color, bordered and maculated with black. This leech varies from two to four inches in length. It inhabits marshes and running streams, and is abundant throughout Europe.¹

¹ A variety of the leech has come into use in Europe, called in commerce *African leeches*. They are of a beautiful light-green color, varying to a deep green, and often inclining to red, with black points on the back, and broad streaks of a bright orange yellow, which are black towards the abdomen. They correspond perfectly with the *Sanguisuga interrupta* of Moquin-Tandon. These leeches draw very well. (P. J., x. 38.) The leeches from Algiers, called in French commerce *dragons* (*Sanguisuga troctena* of Moquin-Tandon), of which considerable numbers have been taken to France, are said by M. A. de Quatrefages, contrary to former opinion, to be quite equal to the European. (J. P. C., 3e sér. xxxiii.) It is stated (P. J., June, 1867) that great numbers of leeches are collected in Australia and sent to Melbourne, whence a large proportion are exported to Europe and America. This leech is said to differ from the ordinary English leech only in that the olive streaks are much lighter in the former.

The great use made of leeches in the modern practice of medicine has occasioned them to become a considerable article of commerce. They are collected in Spain, France, Italy, Germany, and Sweden, and carried in large numbers to London and Paris. They are also frequently brought to this country, as the practitioners in some of our large cities use only the foreign leech, although our own waters furnish an inexhaustible supply of this useful worm.² The indigenous leech was formerly much used in the city of Philadelphia.

2. *Hirudo decora*, Say, Colonel Long's Second Expedition, ii. 268.—The medicinal leech of America has been described by Say under the name of *Hirudo decora*, in the Appendix to the Second Expedition of Colonel Long. Its back is of a deep pistachio-green color, with three longitudinal rows of square spots. These spots are placed on every fifth ring, and are twenty-two in number. The lateral rows of spots are black, and the middle range of a light brownish-orange color. The belly is of the latter color, variously and irregularly spotted with black. The American leech sometimes attains the length of four or five inches, although its usual length is from two to three. It does not make so large and deep an incision as the European leech, and draws less blood. Under the name of *Hirudo australis*, Australian leeches, the British Addendum recognizes *Hirudo quinquestriata*, Schmarda (*Hirudo australis*, Bosisto; *Limnoddella quinquestriata*, R. Blanch), the five-striped or Australian leech, whose dorsal surface is greenish-yellow-brown, with five longitudinal stripes, the ventral surface being greenish-yellow and not spotted. The jaws are large, with forty-eight to fifty teeth, the inner being the larger.

The proper preservation of leeches is an object of importance to the practitioner, as they are liable to a great and sudden mortality. They are usually kept in jars, in clear, soft water, which should be changed twice a week in winter and every other day in summer. The jar must be covered with a linen cloth, and placed in a situation not liable to sudden changes of temperature. They will live a long time and continue active and healthy without any other attention than that of frequently changing the water in which they are kept. Derheims has proposed the following excellent method of preserving them. In the bottom of a large basin or trough of marble he places a bed, six or seven inches deep, of a

² Attempts have been made, in France, on a large scale, to propagate leeches for sale. This is done by means of natural meadows, in which numerous small ponds are made, where the leeches, with certain cautions as to nourishment and preservation, multiply and grow so rapidly as to become a source of profit. In order that they may propagate, it is necessary that they should be fed on blood, which is given them either by causing animals, as horses, cows, etc., to be driven into the meadows, or by obtaining blood from slaughter houses, and, after depriving it of fibrin by agitation, immersing the animals for a time in it while yet warm. (See J. P. C., Jan. and Mai, 1854.)

mixture of moss, turf, and fragments of wood. He strews pebbles above, so as to retain them in their place without compressing them too much or preventing the water from freely penetrating them. At one end of the trough, and about midway of its height, is placed a thin slab of marble or earthenware, pierced with numerous holes, and covered with a bed of moss, which is compressed by a thick layer of pebbles. The reservoir being thus disposed is half filled with water, so that the moss and pebbles on the shelf shall be kept constantly moist. The basin is protected from the light by a linen cover stretched over it. By this arrangement the natural habits of the leech are not counteracted. One of these habits, essential to its health, is that of drawing itself through the moss and roots to clear its body from the slimy coat which forms on its skin and is a principal cause of its disease and death. James Banes recommends that when kept in jars they should be cleansed by means of a whisk of very fine broom or willow, when the water is changed. Lahache, an apothecary at Bruyères, strongly recommends carrageen, or Irish moss (*Chondrus crispus*), as admirably adapted to the habits and wants of the leech, furnishing the animal, he supposes, with nutriment, as it does not die of inanition when thus kept. The water should be renewed in the jars daily. (*J. P. C.*, 4e sér., iii. 128.) Alfred Allchin keeps them in aquaria with growing water-plants and snails, which keep the water pure.¹ (*A. J. P.*, xxviii. 222.)

Uses.—Leeches afford the least painful and in many instances the most effectual means for the local abstraction of blood. They are often applicable to parts which, either from their situation or from their great tenderness when inflamed, do not admit of the use of cups, and in the case of infants are under all circumstances preferable to that instrument. They are indeed a powerful therapeutic agent, and give to the physician, in many instances, a control over disease which he could obtain in no other way.

Franz (*P. J.*, lxxiii. 347) has used *hirudine*, a principle discovered by Hayercraft, which it is asserted increases the coagulability of the blood, as an antihemorrhagic. Extract of leeches, however, has the property of lessening or entirely preventing the coagulation of the blood. According to Hayercraft, the substance which acts as an anti-coagulant is found in the buccal secretion (*P. J.*, 1891). Landois Schultz has shown that this principle is extracted by water (*Th. M.*, 1892, 140). According to Franz, the active anti-coagulation principle of the leech occurs chiefly in the salivary glands anterior to the tenth ring, but is to some extent diffused throughout the whole body. We have been unable to buy leech extract in the American market, but have found that by means of the following process, which

is a modification of that used by Franz, entirely satisfactory results can be obtained in the laboratory. Cut off the leech heads, mince them, rub up with a very fine sand and add to the mass 5 Cc. of seven-tenths per cent. normal sodium chloride solution for each leech head, and heat for twenty minutes over a water bath at 100° C. (212° F.). Treat the bodies of the leeches in a similar manner. Allow the masses from the heads and bodies to stand separately in a cool room for twelve hours; centrifuge the leechhead mass for twenty minutes, then wash the sand in the lower part of the centrifuge, centrifuging the resulting liquid, and mixing the two fluids obtained. Filter the mass containing the bodies of the leeches through cheese cloth under pressure; centrifuge the filtrate; wash the mass with the salt solution, centrifuge the resulting liquid, and add it to the previously centrifuged filtrate. Mix the liquids obtained from the heads with that derived from the bodies, and an active solution is obtained. When using either solution in the laboratory do not estimate by the number of cubic centimeters of the solution, but by the number of leeches represented. According to Franz, in a dog, three leeches per kilo will prevent coagulation of the blood, but we have found that three and one-half leeches per kilo are necessary in America, the difference being probably due to the condition of the leeches, Franz having used the fresh European leeches, and we the leech after transportation and probably deterioration.

In applying leeches to the skin, care should be taken to shave off the hair, if there be any, and to have the part well cleansed with soap and water, and afterwards with pure water. If the leech does not bite readily, the skin should be moistened with a little blood, or milk and water. It is said to bite more freely if the skin has been previously reddened by a sinapism and then washed perfectly clean. Sometimes the leech is put into a large quill open at both ends, and applied with the head to the skin until it fastens itself, when the quill is withdrawn. If it be desirable that the leech shall bite in a particular spot, this end may be attained by cutting a small hole in a piece of blotting paper, and then applying this moistened to the skin, so that the hole shall be immediately over the spot from which the blood is to be taken. Leeches continue to draw blood until they are gorged, when they drop off.¹ The quantity of blood which they draw varies with the part to which they are applied, and the degree of inflammation existing in it. From the loose and vascular textures they will abstract more

¹ As a very efficient mode of applying leeches, it is recommended, after having moistened the skin with pure warm water, to put the leeches into a tumbler half full of cold water, and by an adroit movement invert it upon the part. The leeches are said to attach themselves so rapidly that it seems to the patient as though they made but a single bite. When they are all attached, the glass is to be carefully removed, the water being absorbed, as it runs off on one side, by a sponge or linen cloths.

¹ For other methods of keeping leeches, also of raising them, see U. S. D., 14th ed., 472.

than from those which are firm and compact, and more from an inflamed than from a healthy part. As a rule, our leechers apply six for every fluidounce of blood. A single European leech will draw from half an ounce to an ounce. The quantity may often be much increased by bathing the wound with warm water. Leeches will continue to suck after their tails are cut off, which is sometimes done, although it is a barbarous practice.¹ It is said that they will draw better if put into cold beer, or diluted wine, and allowed to remain until they become very lively. They may be separated from the skin at any time by sprinkling a little salt upon them. After they drop off, the same application will make them disgorge the blood they have swallowed. Some leechers draw the leeches from the tail to the head through their fingers, and thus squeeze out the blood, after which all that is necessary is to put them in clean water, and change it frequently.² Leeches

¹ Under the name of *bdellotomy*, a practice has been introduced into Germany, of making a small incision in the side of the leech while drawing. The blood escapes through the wound, and the animal will continue to suck for a long time, so that one will perform the office of many in the quantity of blood taken.

² Soubelran and Bouchardat, after numerous experiments upon the different modes of fitting the gorged leeches for use again, came to the conclusion that a carefully managed pressure is the best. Two conditions, however, are necessary to success; one that they should be disposed to disgorge the blood, and the other that they should be immersed in warm water previously to the stripping. The first object is effected by common salt. The following plan is recommended. The leeches are to be thrown into a solution of 16 parts of common salt in 100 of water, from which they are to be taken out one by one, and, being held by the tail, are to be dipped into water which feels hot to the hand, but yet can be borne by it, and then passed lightly between the fingers. Thus treated, they easily give up the blood. After being stripped, they should be placed in vessels containing fresh water, which should be renewed once a day. At the end of eight or ten days they are fit for reapplication. (*J. P. C.*, 3e sér., xi. 343 and 350.) It is said that in the French military hospitals a mixture of one part of vinegar with eight parts of water is preferred to salt water for promoting disengagement. (*M. T. G.*, Oct., 1856, p. 375.) It has been stated that if the leeches, after being stripped, be put into water sweetened with a little white sugar, and the solution be renewed several times, at intervals of six or twelve hours, they will speedily recover their activity, and may be reappplied two or three times in the course of a few days. Immersion in camphor water for a few moments is said by Boyce to cause them to vomit the blood. They should afterwards be put into clean water, to be changed in half an hour. Frodsham, of England, has found camphor water preferable to either salt water or diluted vinegar, for disposing the gorged leech to part with blood. Grannat, a French military pharmacist, has found the natural process of disgorging preferable to all others. He placed some gorged leeches in wooden tubs containing at the bottoms a little clay and water, and renewed the water every forty-eight hours. After eight days, the leeches, now in good health, were transferred to a pond prepared for the purpose, where they propagated. He put 1000 leeches in the pond, and at the end of a year had taken out 850 fit for service, without interfering with the reproduction. (*J. P. C.*, 3e sér., xx. 186.) Vayson's plan of preserving leeches has been highly recommended. It consists simply in putting them, after stripping, if they have been used, in an earthenware vessel of the shape of an inverted truncated cone, with holes in the bottom so small as to prevent the escape of the leech, and filled with turfy earth. After the introduction of the leech, the opening to be closed with a coarse cloth. The vessel is then placed in a tub containing water four inches deep. If to be sent to a distance, the earth in the vessel should be moistened throughout.

which are gorged with blood should be kept in a vessel by themselves, as they are more subject to disease, and often occasion a great mortality among the others. They should not be again used until they have recovered their activity. In cases where the bleeding from leech bites continues longer than is desirable, it may be stopped by continued pressure, with the application of lint, by the use of collodium, or by touching the wounds with lunar caustic. A little cotton, impregnated with a saturated solution of alum in boiling hot water, and, after it has become sufficiently cool, but before the alum has begun to crystallize, pressed upon the wound, will often prove effectual. Another mode of repressing the hemorrhage is to press upon the bite a piece of thin caoutchouc, previously softened upon one side by heat, so as to become adhesive. If lunar caustic be applied, the stick must first be brought to a fine point, which is to be inserted in the wound. Some have even recommended the use of a fine wire made red hot. When the part wounded is without a bony basis, pressure may be made by pinching the wound between the fingers. It may sometimes be necessary, in the case of a deep bite, to sew the wound, which is readily done with a single stitch of the needle, that need not penetrate deeper than the cutis.

HOMATROPINÆ HYDROBROMIDUM.

U. S., Br.

HOMATROPINE HYDROBROMIDE

[Homatropine Hydrobromate]

(hō-măt-rō-pī'næ hÿ-drō-brō-mī-dŭm)

"The hydrobromide [$\text{HBr} \cdot \text{C}_{16}\text{H}_{21}\text{NO}_3$] of an alkaloid obtained by the condensation of tropine and mandelic acid. It should be kept in well-stoppered vials, protected from light." *U. S.* "The hydrobromide, $\text{C}_{16}\text{H}_{21}\text{NO}_3 \cdot \text{HBr}$, of an alkaloid prepared from tropine." *Br.*

Bromhydrate d'Homatropine, *Fr. Cod.*; Homatropinum hydrobromicum, *P. G.*; Homatropinhydrobromid, Bromwasserstoffsaures Homatropin, Bromwasserstoffsaures Oxytoluyltropin, *G.*

Preparation.—This alkaloidal salt was first admitted to the British Pharmacopœia in the additions of 1890. Homatropine, $\text{C}_{16}\text{H}_{21}\text{NO}_3$, is prepared by evaporating a mixture of tropine, $\text{C}_8\text{H}_{15}\text{NO}$ (obtained through the saponification of hyoscyamine), and mandelic acid (phenyl-glycollic), $\text{C}_6\text{H}_5\text{CH}(\text{OH})\text{COOH}$, with diluted hydrochloric acid; mandelic acid may be produced by acting on amygdalin with hydrochloric acid, or synthetically from benzaldehyde and hydrogen cyanide.

Properties.—Homatropine hydrobromide is officially described as follows: "A white, odorless, crystalline powder, or rhombic prisms, having a bitter taste. Soluble in 5.7 parts of water, 32.5 parts of alcohol, and in 620 parts of chloroform at 25° C. (77° F.); soluble in

8.7 parts of alcohol at 60° C. (140° F.); insoluble in ether. At 213.8° C. (417° F.) it melts. It leaves no residue upon incineration. Its aqueous solution is neutral to litmus paper, and is not precipitated by tannic acid T.S. or platinic chloride T.S. It contains no water of crystallization. If 2 Cc. of chloroform be shaken with 1 Cc. of an aqueous solution of the salt (1 in 10) to which a few drops of chlorine water have been cautiously added, the chloroform should assume a brownish color. Iodine T.S., when added to solutions of Homatropine Hydrobromide, produces a brown precipitate; silver nitrate T.S., a creamy white precipitate. If to an aqueous solution containing 0.1 Gm. of the salt an excess of potassium hydroxide T.S. be added, this liquid shaken out with ether, and the ether allowed to evaporate spontaneously, the crystals which form should have a melting point of 96° C. (204.8° F.). If 1 Cc. of an aqueous solution of the salt (1 in 100) be made alkaline with ammonia water, shaken out with chloroform, and the chloroformic solution evaporated to dryness, the residue should turn yellow and finally brick-red when warmed with about 1.5 Cc. of a solution made by dissolving 1 part of mercuric chloride in 50 parts of a mixture of alcohol 5 volumes and water 3 volumes (absence of most other alkaloids except atropine and hyoscyamine). If sulphuric acid containing a trace of potassium dichromate be added to a crystal of the salt, an evanescent pink color will be produced, which changes rapidly to green. If 0.01 Gm. of the salt be added to 5 drops of nitric acid, and evaporated to dryness in a porcelain dish, the residue should not acquire a violet color upon the addition of a few drops of alcoholic potassium hydroxide T.S. (absence of atropine, hyoscyamine, or hyoscyne)." U. S. "A white crystalline powder or aggregation of minute trimetric crystals, soluble in 6 parts of cold water, and in 133 parts of absolute alcohol. The solutions should be neutral to litmus. A dilute aqueous solution, when applied to the eye, powerfully dilates the pupil. Heated on platinum foil it fuses and burns without leaving an appreciable residue. If 0.2 cubic centimetre of chloroform be shaken with 1 cubic centimetre of a 10 per cent. aqueous solution, to which solution of chlorine has been cautiously added, the chloroform will assume a brownish color. A 2 per cent. aqueous solution yields no precipitate on the cautious addition of solution of ammonia previously diluted with twice its volume of water, but dilute solution of potassium hydroxide produces in it a white precipitate, soluble in excess of the reagent. Solution of iodine causes a brown and test-solution of mercuric chloride a white precipitate. If about 0.01 gramme be dissolved in a little water and the solution rendered alkaline with solution of ammonia and shaken with chloroform, the separated chloroform will leave on evaporation a residue which will turn yellow,

and finally brick-red, when warmed with about 1.5 cubic centimetres of a 2 per cent. solution of mercuric chloride in a mixture of five volumes of alcohol (90 per cent.) and three volumes of water. When treated with fuming nitric acid and potassium hydroxide, as described under 'Atropina,' no reddish-violet coloration is developed (distinction from atropine), the residue becoming reddish yellow. It affords the reactions characteristic of hydrobromides." Br.

Uses.—Homatropine hydrobromide is stated to produce, when taken internally, symptoms somewhat similar to those caused by atropine, except that the pulse rate is rendered slower instead of more rapid. Experiments made upon the reptilian heart indicate that the slowness of the pulse and the fall of the arterial pressure which has been found to accompany it are due in large part or altogether to direct action upon the heart itself. No cases of fatal poisoning are, so far as we know, on record, but in experiments made upon the lower animals death has been found to be due to a centric respiratory paralysis.

Homatropine hydrobromide has not been used internally to any extent, but is largely employed as a local mydriatic, having the advantage over atropine of being much less irritating to the conjunctiva and much less prone to produce serious systemic disturbance. The pupil begins to dilate in from seven to twenty minutes after the instillation; accommodation fails in from forty to ninety minutes, while usually the recovery is complete in from one to three days. For simple dilatation of the pupil, a solution of the strength of four grains to the ounce is sufficient. When it is desired to paralyze accommodation completely, the 2 per cent. solution may be employed.

Dose, internal, from one one-hundred and fiftieth to one-sixtieth of a grain (0.0004 to 0.001 Gm.).

Off. Prep.—Lamellæ Homatropinæ, Br.

HUMULUS. U. S. (Br.)

HOPS

(hū'mū-lūs)

"The carefully dried strobiles of *Humulus Lupulus* Linné (Fam. *Moraceæ*), bearing their natural glandular trichomes." U. S. "The dried strobiles of *Humulus Lupulus*, Linn., from cultivated plants." Br.

Lupulus, Br.; Hop; Strobili Humuli, s. Lupuli; Houblon, Fr. *Od.*; Hopfen, G.; Luppolo, It.; Lupulo (Fruto de), Hombrecillo, Sp.

Humulus Lupulus, L., *Sp. Pl.* (1753), 1028; Willd., *Sp. Plant.* iv. 769; Bigelow, *Am. Med. Bot.*, iii. 163.—The root of the hop is perennial, and sends up numerous annual, angular, rough, flexible stems, which twine around neighboring objects in a spiral direction from left to right, and climb to a great height. The leaves are

opposite, and stand upon long footstalks. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep green color on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the footstalks are two to four smooth, ovate, reflexed stipules. The flowers are numerous, axillary, and furnished with bracts. The male flowers are a yellowish white, and arranged in panicles; the female, which grow on a separate plant, are pale green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears near its base, on its inner surface, two flowers, consisting of a roundish compressed germ, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain, each, at its base, two small seeds, surrounded by a yellow, granular powder. The genus *Humulus* is placed with *Morus* and *Cannabis* in a separate family, *Moraceæ*, by Engler and Prantl.

The hop plant is a native of North America and Europe. In parts of New England, New York, and Michigan it is extensively cultivated, and most of the hops consumed in the United States are supplied by those districts. England probably produces the largest quantity of hops in the world, with Germany next in order. The part of the plant used is the fruit or strobiles. These, when fully ripe, are picked, dried by artificial heat, packed in bales, and sent into the market under the name of hops.

Hops consist of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow color, and contain near the base two small, round, black seeds. They are officially described as "ovoid-cylindrical, about 3 Cm. long, consisting of a thin, hairy flexuous rachis and numerous yellowish-green to pale brown obliquely ovate, membranaceous scales with a glandular-hairy base, frequently infolded on one side, enclosing a subglobular, light brown, very glandular akene; odor strong and agreeable; taste aromatic and bitter." *U. S.* Though brittle when quite dry, they are pulverized with great difficulty. Their odor is strong, peculiar, somewhat narcotic, and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction, but the first mentioned property is dissipated by long boiling. The most active part of hops is a substance formed on the surface of the scales, and, in the dried fruit, existing in the state of very small granules. This substance was called *lupulin* by A. W. Ives of New York, by whom its properties were first investigated and made generally known, though it was previously noticed by Sir J. E. Smith of England, and Planche of France. The scales themselves, however, are not destitute of virtues, and contain, as shown by

Payen and Chevallier, the same active principles as does lupulin, though in less proportion.¹

LUPULINUM. *U. S. Lupulin.*—Although lupulin is official (see *Lupulinum*), its characteristics are described here in order that the constituents of hops may be all considered together. Lupulin is obtained by rubbing or threshing and sifting the strobiles, of which it constitutes from one-sixth to one-tenth by weight. It is in the state of a yellowish powder, mixed with minute particles of the scales, from which it cannot be entirely freed when procured by a mechanical process. It has the peculiar flavor of hops, and appeared to Lebaillif and Raspail, when examined by the microscope, to consist of globules filled with a yellow matter, resembling in this respect the pollen of vegetables; but from the investigations of Personne it would seem to be of the nature of a gland, commencing in a cell formed among those of the epidermis, and, when fully developed, secreting a resinous matter. (*J. P. C.*, 3e sér., xxvi.) It is inflammable, and when moderately heated becomes somewhat adhesive. The odor of lupulinic grains resides in the essential oil. This is obtained to the extent of 0.9 per cent. by distilling hops with water. When distilled from the fresh strobiles the oil has a greenish color, but a reddish brown when old hops have been employed. It is devoid of rotatory power, neutral to litmus paper, and

¹Hops are often subjected in Germany to the fumes of burning sulphur, because of the supposition that they keep better when thus treated. Besides, by being partially bleached by the process, old hops, which have suffered from time, having become darker, generally spotted, and weaker, assume a brighter appearance, as if fresher, and generally command a better price in the market. To detect the consequent presence of sulphurous acid, the brewers put a silver spoon in a mixture of hops and water, under the impression that it will produce a black stain upon the silver. But this test will answer only when applied within a fortnight after the use of the sulphur. A more delicate method is that of Heidenreich, who puts 20 or 30 cones of the hops in a flask with zinc and hydrochloric acid, and passes the hydrogen evolved through solution of lead acetate. If sulphurous acid be present, hydrogen sulphide will be produced, which will occasion a dark precipitate with the solution. But even this plan often fails when the hops have been kept more than three or four weeks. A modification of this test has been proposed by R. Wagner. For the solution of lead acetate used in Heidenreich's method there is to be substituted a solution of sodium nitroprusside, so weak as to have a very light brown color, to which have been added a few drops of solution of potassium hydroxide. If the gas evolved contain the minutest proportion of sulphur, a violet color will be produced when the first bubble passes into the solution; and this will by a continuance of the process become a magnificent purple. The least trace of sulphurous acid may thus be found, but a few months after the sulphuring of hops none at all can be detected.

Hops are said to be sometimes threshed in order to separate the lupulin, which is sold separately. Their efficiency is thus, no doubt, greatly impaired. Hops thus treated have the scales more or less broken: and any parcel presenting this appearance is to be suspected. Hops often contain a variable quantity of lupulin in consequence of the granules of this substance separating, especially on agitation, and seeking the lower portion of the mass, which thus becomes richer, while the upper is poorer. They should always be examined in reference to the lupulin they contain, and, if nearly or quite destitute of it, should be deemed of inferior value and not be used medicinally.

gives no remarkable coloration with concentrated sulphuric acid. According to Chapman (*J. Chem. S.*, 1895, 54, 780) the essential oil consists of two terpenes, one $C_{10}H_{16}$, and the other $C_{10}H_{18}$, boiling between 160° and 171° , and a sesquiterpene called *humulene*, boiling at 263° to 266° . This latter makes up almost two-thirds of the oil. There is also a small amount of an oxygenated constituent, probably $C_{10}H_{18}O$. The bitter principle formerly called *lupulin* or *lupulite* was first isolated by Lerner (*J. Pr. Chem.*, 101), who called it the *bitter acid of hops* (*Hopfenbittersaure*). It crystallizes in large brittle rhombic prisms, and possesses the peculiar bitter taste of beer. Its composition is $C_{55}H_{80}O_7$. The main contents of the hop gland consist of wax (*myricyl palmitate*, according to Lerner) and resins, one of which is crystalline and unites with bases. Besides the constituents of the glands, hops contain, according to Etti, *lupulo-tannic acid* and *phlobaphene*. The former is a whitish, amorphous mass, soluble in alcohol, hot water, or acetic ether, but not in ether. By heating the *humulo-tannic acid* to 130° C., or by boiling its aqueous or alcoholic solution, it gives off water and is transformed into *phlobaphene*, a dark-red amorphous substance, $2C_{55}H_{84}O_{13} - H_2O = C_{50}H_{76}O_{25}$.

The latter substance, on boiling it with diluted mineral acids, becomes hydrolyzed, and furnishes glucose and *hop-red*, according to the reaction:

From raw *phlobaphene*, ether removes the bitter principles of hops, a colorless crystallizable and a brown amorphous resin, besides chlorophyll and essential oil. (*Pharmacographia*, 2d ed.) The existence of a peculiar alkaloid in hops, suggested by Lerner in 1863, has been determined by Griessmayer. A concentrated decoction of hops was distilled with potassium or magnesium hydroxide, the distillate neutralized with hydrochloric acid, evaporated to dryness, and treated with cold absolute alcohol to remove ammonium chloride; the alcoholic liquid was heated to boiling and cooled, when much trimethylamine chloride crystallized. The residuary liquid was filtered, the filtrate evaporated, first by a water bath and then spontaneously, the residue was redissolved in water in a narrow cylinder, agitated with potassium hydroxide and ether, and the ethereal liquid allowed to evaporate spontaneously. The remaining alkaline liquid had a peculiar odor recalling that of conine, and a cooling but not bitter taste. It soon exhibited small crystals, and finally solidified completely. The author supposed that these crystals were impurities, and that the pure alkaloid is liquid or gaseous. He proposed for it the name of *lupuline*. (*A. J. P.*, 1874.) Lastly, Etti found arabic (pectic) acid, phosphates, nitrates, malates, citrates, and also sulphates, chiefly of potassium, to occur in hops. The amount of ash afforded by hops dried at 100° C. would appear to be on an average

about 6 to 7 per cent. H. Bungener has isolated from hops a bitter crystalline substance, $C_{55}H_{80}O_4$, which is insoluble in water, but soluble in alcohol and alkaline solutions. He believes it to be identical with Lerner's hop-bitter acid, to be feebly acid, and to possess the character of an aldehyde. (*P. J.*, 1884.)

Uses.—Hops are tonic and have been esteemed a narcotic. The complaints in which they have been used are *dyspepsia*, and the nervous tremors, *wakefulness*, and *delirium of drunkards*, but their medicinal properties are so feeble as rarely, in practice, to be perceptible.

An *infusion* prepared with half an ounce of hops and a pint of boiling water may be given in the dose of four fluidounces (120 Cc.) three or four times a day. The tincture is a British official preparation of hops, but the alcohol probably acts more decidedly upon the system than the hops. (See *Tinctura Lupuli*.) A pillow of hops has proved useful in allaying restlessness and producing sleep in nervous disorders. They should be moistened with water containing a trace of glycerin previously to being placed under the head of the patient, in order to prevent rustling. Fomentations with hops, and cataplasms made by mixing them with some emollient substance, are often beneficial in local pains and tumefactions.

The effects of hops may be obtained most conveniently by the use of *lupulin* (see *Lupulinum*), which, although at one time much employed as an anaphrodisiac, has fallen into deserved desuetude.

Dose, thirty to ninety grains (2.0 to 5.8 Gm.).

HYDRARGYRI CHLORIDUM CORROSIVUM. U. S. (Br.)

CORROSIVE MERCURIC CHLORIDE [Bichloride of Mercury, Corrosive Sublimate, Mercuric Chloride]

(hŷ-dră'gy-rĭ ċhlŏ'rĭ-dŭm cŏr-rŏ-sĭ-vŭm)

HgCl₂ = 268.86

"It should contain not less than 99.5 per cent of pure Mercuric Chloride, and be kept in well-stoppered bottles." *U. S.* "A salt, Hg Cl₂, obtained as a sublimate by heating a mixture of mercuric sulphate, sodium chloride, and a little black oxide of manganese." *Br.*

Hydrargyri Perchloridum, Br., Sublimatus Corrosivus, Chloruretum (Chloretum) Hydrargyricum, Hydrargyrum Corrosivum Sublimatum, Hydrargyri Bichloridum; Hydrargyrum Muriaticum Corrosivum, Sublimatus Corrosivus, Sublimatum corrosivum, Mercurius Sublimatus Corrosivus; Corrosive Chloride of Mercury, Perchloride of Mercury; Sublimé corrosif, Chlorure mercurique, Fr. *Ood.*; Deutochlorure de Mercure, Fr.; Hydrargyrum Bichloratum, P. G.; Quecksilberchlorid, Aetzender Quecksilbersublimat, G.; Biclouro di mercurio, It.; Cloruro mercurio, Sp.

The former official processes for this salt will be found in the foot-note.¹

¹ "Take of Mercury twenty-four troyounces; Sulphuric Acid thirty-six troyounces; Chloride of Sodium

The names given in the two Pharmacopœias to this important chloride do not exactly correspond. It is called *Hydrargyri Chloridum Corrosivum* in the U. S. Pharmacopœia, and *Hydrargyri Perchloridum* in the British. We prefer the former, as indicating, beyond any possibility of mistake, the article intended, as well as its corrosive property. Perchloride and subchloride are hardly sufficiently distinctive, when a mistake may be so serious as that of confounding corrosive sublimate and calomel. In the first British Pharmacopœia corrosive sublimate was recognized as the official title, which was a sufficient guarantee of security; but, unfortunately, it was deemed proper, immediately after the official title, and in close connection with it, to define the salt as chloride of mercury, in conformity with the view, adopted in that work, of the atomic weight of mercury. With many persons calomel is still the chloride of mercury, so that there is some risk that, should calomel be prescribed by this title, corrosive sublimate may be dispensed for it, with dangerous if not fatal effects to the patient. Indeed, death has at least in one recorded instance occurred in consequence of this confusion of nomenclature, and our official guides should take especial care to guard against such mistakes, instead of contributing to them. The British Pharmacopœia (1898) uses for the English names mercuric chloride for corrosive sublimate and mercurous chloride for calomel, but these names are not used in prescription writing.

Preparation.—The first step in making corrosive sublimate is to form mercuric sulphate, by heating sulphuric acid and the metal to-

eighteen troyounces. Boil the Mercury with the Sulphuric Acid, by means of a sand-bath, until a dry white mass is left. Rub this, when cold, with the Chloride of Sodium in an earthenware mortar; then sublime with a gradually increasing heat." *U. S.* 1870. "Take of Persulphate of Mercury *twenty ounces* [avoirdupois]; Chloride of Sodium, dried, *sixteen ounces* [av.]; Black Oxide of Manganese, in fine powder, *one ounce* [av.]. Reduce the Persulphate of Mercury, and the Chloride of Sodium each to fine powder, and, having mixed them and the Oxide of Manganese thoroughly by trituration in a mortar, put the mixture into an apparatus adapted for sublimation, and apply sufficient heat to cause vapors of perchloride of mercury to rise into the less heated part of the apparatus which has been arranged for their condensation." *Br.* 1885.

In order to understand the above processes, which are the same in principle, it is necessary to premise that corrosive sublimate is mercuric chloride, consisting of two atoms of chlorine and one atom of mercury. By boiling sulphuric acid in excess with mercury to dryness, a white salt (mercuric sulphate) is formed, according to the reaction:

(See *Hydrargyri Persulphas*.) When this is mixed with sodium chloride (common salt), and the mixture exposed to a subliming heat, a mutual decomposition takes place, according to the reaction:

The mercuric chloride thus formed sublimes, and the sodium sulphate remains behind. The quantities for mutual decomposition are two molecules of sodium chloride and one molecule of mercuric sulphate. The British formula differs from that of the U. S. F. 1870 in ordering mercuric sulphate ready formed, instead of preparing it as the first step of the process, and in the use of a small proportion of manganese dioxide, intended to convert into mercuric any mercurous salt that may be in the sulphate, and thus prevent the formation of mercurous chloride. (See *Hydrargyri Persulphas*.)

gether in an iron pot so arranged as to carry off the unwholesome fumes of sulphurous oxide, which are copiously generated. The dry salt obtained is then mixed with sodium chloride, and the mixture sublimed in an iron pot lined with clay and covered by an inverted earthen pan. A. T. Thomson of London, England took out a patent for forming corrosive sublimate on the large scale, by the direct combination, by combustion, of gaseous chlorine with heated mercury. The product is stated to be perfectly pure; and to be afforded at a lower price than the sublimate made in the usual way. In order that the combination may take place, the mercury need not be heated to its boiling point, but only to a temperature between 149° and 204° C. (300° and 400° F.). According to MacLagan, corrosive sublimate made by this process is liable to the objection that a proportion of calomel is always formed, occasionally amounting to 10 per cent. It may sometimes be useful to know how to make a small quantity of corrosive sublimate in an emergency. This may be done by dissolving mercuric oxide (red precipitate) in hydrochloric acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. Here a double decomposition takes place, resulting in the formation of water and the chloride.

Properties.—Corrosive mercuric chloride is officially described as in "heavy, colorless, rhombic crystals, or crystalline masses, odorless, and having an acrid and persistent metallic taste; permanent in the air. When in fine powder, it is soluble in 13 parts of water, 3 parts of alcohol, and in about 14 parts of glycerin at 25° C. (77° F.); soluble in 2 parts of boiling water, and in 1.2 parts of boiling alcohol. If 1 Gm. of finely powdered Mercuric Chloride be dissolved in 10 Cc. of alcohol or 20 Cc. of water, it should leave not more than 0.005 Gm. of residue. It fuses at 265° C. (509° F.) to a colorless liquid, and at about 300° C. (572° F.) it volatilizes in dense, white vapors, leaving no appreciable residue. The aqueous solution reddens blue litmus paper, but becomes neutral to litmus paper upon the addition of sodium chloride. With ammonia water the aqueous solution of the salt yields a white precipitate; with an excess of hydrogen sulphide a black one; with potassium iodide T.S. a red one, soluble in an excess of the reagent; and with silver nitrate T.S. a white precipitate, insoluble in nitric acid. If to 0.5 Gm. of Mercuric Chloride, dissolved in 20 Cc. of water, 5 Cc. of hydrochloric acid be added, and the solution be completely saturated with hydrogen sulphide, allowed to stand for several hours in a well-corked flask until the precipitate has subsided, and then filtered, the filtrate should be colorless and leave no weighable residue upon evaporation (absence of many foreign salts). If the precipitate obtained in the preceding test, after washing with about 100 Cc. of water and draining, be rinsed into a beaker with about 20 Cc. of water, and then

5 Cc. of stronger ammonia water added, and if after covering and digesting the mixture for about 15 minutes on a bath of boiling water, it be rinsed upon a filter and washed with a little water, the filtrate and washings after evaporating to dryness, moistening with 6 drops of nitric acid, and again drying, should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17). If the precipitated sulphide remaining upon the filter be treated with diluted nitric acid (1 in 4), warmed, and then filtered, the filtrate should leave no weighable residue upon evaporation and gentle ignition (limit of foreign metals).¹ U. S. "Heavy colorless masses of prismatic crystals, possessing a highly acrid metallic taste. Soluble in 16 parts of cold and 2 parts of boiling water, 3 parts of alcohol (90 per cent.), 4 parts of ether, and, on trituration, in 2 parts of cold glycerin. It affords the reactions characteristic of mercuric salts and of chlorides. When heated it sublimes without decomposition, leaving only a trace of fixed residue. When heated with excess of lime it yields 72.8 to 73.8 per cent. of metallic mercury." Br.

Ether is capable of removing corrosive sublimate, to a considerable extent, from its aqueous solution when agitated with it. According to Mialhe, ether will not dissolve it when accompanied by a considerable quantity of mercuric oxide and a chloride of an alkalisable metal. Sulphuric, nitric, and hydrochloric acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapors, which condense, on cool surfaces, in white, shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum*.) The former precipitate is mercuric oxide, which has the property of evolving oxygen and of being reduced to metallic globules when exposed to heat. This oxide is formed in the process for preparing *aqua phagedanica*, called also *lotio flava*, or *yellow wash*, which is obtained by mixing half a drachm of corrosive sublimate with a pint of lime water. (See *Lotio Flava*.) Corrosive sublimate forms, with ammonium chloride and sodium chloride, compounds which are more soluble than the uncombined mercurial salt. It is on this account that aqueous solutions of sal ammoniac or of sodium chloride dissolve much more corrosive sublimate than simple water. The combination of corrosive sublimate with ammonium chloride was formerly called *sal alembroth*, or *salt of wisdom*. According to F. Hinterberger, corrosive sublimate is capable of combining with quinine and cinchonine. (*Chem. Gaz.*, ix. 211.) By dissolving one part of corrosive sublimate and a hundred parts of sodium chloride in distilled water and evaporating to dryness, a soluble preparation is obtained which does not coagulate albumen.

(A. J. P., xlv. 11.) J. F. Brown (C. D., 1896, 425) recommended for dispensing purposes a solution of mercuric chloride of such strength that ten minims contain one grain, made by dissolving ninety-six grains of corrosive sublimate in one and a half ounces avoirdupois of glycerin and six fluidrachms of distilled water by the aid of heat, then cooling the solution and adding distilled water until the solution measures two fluidounces.

Tests.—Pure corrosive chloride of mercury sublimes, when heated, without residue, and its powder is entirely and readily soluble in ether. Consequently, if a portion of any sample should not wholly dissolve in ether, or if it should not evaporate entirely, the presence of some impurity is proved. If calomel be present, and it frequently is, it will not be wholly soluble in water.¹ Arsenic is reported to be a frequent impurity in corrosive sublimate. (See paper by J. Granville Smith, A. J. P., 1877, p. 397.) It can be readily detected by the test of U. S. P. (8th Rev.). (See above.) Corrosive sublimate is incompatible with many of the metals, the alkalies and their carbonates, soap, lime water, tartar emetic, silver nitrate, the lead acetates, the potassium and sodium sulphides, the soluble iodides, and all the sulphhydrates. It is decomposed by many vegetable and some animal substances. According to A. T. Thomson, it produces precipitates in infusions or decoctions of chamomile, horseradish, calumba, cinchona, gambir, rhubarb, senna, sinaruba, and oak bark. Mialhe and Lepage have shown that corrosive sublimate is slowly converted into calomel by syrup of sarsaparilla and syrup of honey, but is not changed by contact with pure syrup. Samuel Kennedy (*Ph. Rec.*, 1888, p. 201) proved conclusively that when corrosive sublimate was dissolved in compound syrup of sarsaparilla, as frequently prescribed, precipitation invariably occurred. He found that if sodium chloride in quantity equalling that of the mercurial used were added, precipitation was greatly retarded.

Uses.—Corrosive sublimate is a very powerful preparation, operating quickly, and, if not properly regulated, producing violent effects. It is less likely to salivate than most other mercurials. In doses of one-hundredth to one-sixtieth of a grain (0.0006 to 0.0011 Gm.) it often seems to act as a tonic to the general nutrition, and even in somewhat larger dose it may exert its peculiar influence without any obvious alteration of the vital functions, except, perhaps, a slight increase in the frequency of the pulse, and in the secretions from the skin and kidneys. Sometimes, however, it purges, but this effect may be obviated by combining it with a little opium. In larger doses it occa-

¹ Bullot, having noticed in some corrosive sublimate an insoluble portion consisting of minute yellowish granules, found on examination that it was an aniline product. He surmised that the drug had been thrown into commerce after having been used in the preparation of aniline dyes. (*J. P. C.*, 4e sér., xviii. 414.)

sions nausea, vomiting, griping pain in the bowels, diarrhoea, and other symptoms of gastric and intestinal irritation, and in still larger quantities produces all the effects of a violent corrosive poison. It has long been used as a remedy in *syphilis*, in all stages of which it has been highly recommended. It is especially valuable in the advanced stages of the disorder, when there is no cachexia. When a very rapid impression is desired it is not as useful as calomel. It is the best of all the preparations of mercury for hypodermic use in syphilitic diseases. From one-twentieth to one-tenth of a grain (0.003 to 0.006 Gm.) dissolved in ten minims of water may be thrown deeply into the muscles, preferably of the back. If it produces much smarting one-fourth of a grain of cocaine should be injected and immediately followed, without removal of the needle, by the corrosive sublimate. Corrosive sublimate has been used with more or less lack of success in most chronic diseases involving wide spread nutritive changes, such as *chronic rheumatism*, *cutaneous diseases*, etc.

Externally employed, corrosive sublimate is stimulant, escharotic, and germicidal. A solution in water, containing one-eighth grain in the fluidounce, is employed as an injection in *gleet*, and as a collyrium in chronic *venereal ophthalmia*. A stronger solution, containing one or two grains in the fluidounce, is an efficacious wash in *lepra* and other scaly eruptions. Dissolved in water, in the proportion of five to ten grains to the fluidounce, it may be used with much benefit in *venereal ulcers* of the throat, to which it should be applied by means of a camel's-hair pencil. With lime water it forms the *aqua phagedenica* of the older writers, employed as a wash for ill-conditioned *ulcers*. The powdered chloride has been used as an escharotic, but is, in general, inferior to silver nitrate or potassium hydroxide. In *onychchia maligna*, however, it is employed with great advantage, mixed with an equal weight of zinc sulphate, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the ulcer heals.¹ This practice originated, we believe,

with Perkins of Philadelphia, and was highly recommended by Physick. Geo. B. Wood often employed it with success. A solution of corrosive sublimate in collodion (four parts to thirty) has been used as a caustic, for the destruction of *navi materni*, and for other purposes. It can be very accurately applied, but its use requires care, as fatal poisoning has followed a single application of the alcoholic solution of corrosive sublimate to a moderate surface of *ringworm*. (L. L., 1871, ii. 413.) It is applied by means of a camel's-hair pencil.

Corrosive sublimate is one of the most powerful of known germicides, a solution of one part of it in twenty thousand of water being sufficient to kill micrococci and bacilli in active growth, while a solution of one in one thousand will rapidly destroy bacterial spores. According to Koch, as little as one part of corrosive sublimate in three hundred thousand of a proteid solution will prevent the germination of the spores of the bacillus of anthrax. As, however, ammonia and several other chemical substances habitually found in masses of filth rapidly decompose mercuric chloride, the latter is scarcely available for most disinfectant purposes on a large scale. For the purposes of antiseptics in surgery, however, corrosive sublimate is probably the most generally useful and effective of the known germicides. The solution of one in one thousand may be used for washing the hands, disinfecting furniture, etc., and is even employed in the disinfecting of wounds; usually, however, a much weaker solution than that just mentioned is employed by the surgeon. It is rarely if ever justifiable to use upon a mucous surface or a wound a solution stronger than one in two thousand, and if the solution is to be used freely and continuously, as in washing out the vagina, etc., one in ten thousand is as strong as should be employed; indeed, the employment of a vaginal wash of this strength has been followed by violent poisoning. As long ago as 1891 Sebille collected 148 cases of poisoning by vaginal injections. (See H. C. Wood, Jr., *Am. Med.*, Dec. 1902.) In a number of cases a solution of one part in fifteen hundred used locally by the surgeon has produced death, preceded by constitutional symptoms.

For the purpose of convenience of surgeons, *corrosive sublimate tablets* are now largely prepared and used. The amount of corrosive sublimate in these tablets should be so calculated as to yield, with the measures of water ordinarily used, solutions of convenient strength. Thus, if each tablet contains 7.3 grains of corrosive sublimate, one tablet dis-

¹ *Antiseptic Dressings*.—The following directions are given in *Ph. Rund.*, Prague, for antiseptic dressings to be used in the German army:

Corrosive Sublimate Gauze.—Dissolve 50 Gm. mercuric chloride in 5000 Gm. alcohol and add 7500 Gm. distilled water, 2500 Gm. glycerin, and 0.5 Gm. fuchsin, the latter being added for the purpose of readily distinguishing the corrosive sublimate gauze from others. Four hundred metres of gauze are well kneaded in this solution and allowed to soak for fifteen minutes; the gauze is then strongly pressed and well dried on wash-lines, being protected from light and dust.

Corrosive Sublimate Cotton.—Absorbent cotton is soaked in the above solution and dried in loose layers. It has been stated that the cotton has a dissolving effect upon the mercuric chloride, mercury being fixed upon the cotton as oxide, a certain proportion of mercurous chloride being formed at the same time. (*A. J. P.*, 1893, 451.)

Corrosive Sublimate Catgut.—A 5 per cent. aqueous solution of corrosive sublimate is prepared, in which

thin catgut is soaked for about eight hours, and the thicker kinds for ten or twelve hours. The catgut is subsequently kept in vials with alcohol.

Corrosive Sublimate Silk is prepared by soaking well washed ligature silk in a solution of 5 parts of corrosive sublimate in 100 parts of water and 20 parts of glycerin. After drying it is wrapped in oiled silk or other water-proof material, and, before using, it is dipped into a 3 per cent. phenol solution, or a 1 per cent. solution of corrosive sublimate.

solved in a pint of water will yield a solution of one in one thousand. Tablets are found in the market one-half this strength, one tablet making only half a pint of 1-1000 solution. In order to make the tablets readily soluble, the corrosive sublimate is usually compressed with some powdered ammonium chloride or tartaric acid; it is asserted of the latter addition, upon the authority of Laplace, that tartaric acid prevents the precipitation of the mercury as an insoluble albuminate. The proportions used by the manufacturers are as follows: 7.7 grains of corrosive sublimate and 7.3 grains of ammonium chloride in each tablet, one tablet making one pint of 1-1000 solution. The tablets containing tartaric acid are usually made one-half this strength, as follows: 3.85 grains of corrosive sublimate and 19.25 grains of tartaric acid in each tablet. It is essential that the tablets be colored or in some way marked so that the attention may be drawn to their nature, and accidental poisoning prevented.

Dose, of corrosive sublimate, from the one-hundredth to an eighth of a grain (0.0006 to 0.008 Gm.), preferably given after meals, in pill or solution. The pill is usually prepared with crumb of bread; care should be taken that the medicine be equally diffused through the pilular mass before it is divided.

Toxicological Properties.—Swallowed in poisonous doses, it produces burning heat in the throat, excruciating pain in the stomach and bowels, excessive thirst, anxiety, nausea and frequent retching with vomiting of bloody mucus, diarrhoea and sometimes bloody stools, small and frequent pulse, cold sweats, general debility, difficult respiration, cramps in the extremities, faintings, insensibility, convulsions, and death. The mucous membrane of the stomach exhibits, on dissection, signs of the operation of a violent corrosive poison. These symptoms are sometimes followed or conjoined with others indicating an excessive mercurial action upon the system, such as inflammation of the mouth and salivary glands, profuse salivation, fetid breath, etc. The chief symptom of corrosive sublimate poisoning which distinguishes it from poisoning by antimony, arsenic, or other corrosive metallic irritant is the fact that the stools are very frequent, smallish, and composed chiefly of mucus and blood. A case is on record of death, in an infant, from the constitutional effects of corrosive sublimate sprinkled upon an excoriated surface, and in two instances of children, the one seven and the other nine years old, death with all the symptoms of internal poisoning, followed the application to the scalp of an ointment said to consist of one part of the corrosive chloride to four parts of tallow. (*Dublin Q. J.*, Aug. 1854.) In the inferior animals, in whatever mode introduced into the system, it produces symptoms and lesions similar to those which it causes in man. In the treatment of poisoning by corrosive sublimate, Orfila recom-

mends the free use of the white of eggs beaten up with water. The albumin forms an insoluble and comparatively innocent compound with the corrosive sublimate, and the liquid by its bulk dilutes the poison, and distends the stomach so as to produce vomiting.

It is, however, asserted by Lassaigue that this compound of albumin and corrosive sublimate, when recently precipitated, is soluble in acid and alkaline liquids, and in solutions of potassium, sodium, and calcium chlorides. (See *J. P. C.*, xxiii.) It is also soluble in an excess of albumin, whether introduced into the stomach or previously existing there. It is, therefore, important, at the same time that the antidote is used, to evacuate the stomach before the newly formed compound can be dissolved. If eggs cannot be procured, wheat flour may be substituted, gluten having, according to Taddei, the same effect as albumin. Milk also has been recommended, in consequence of the insoluble compound which casein forms with the poison. Besides the antidotes mentioned, Peruvian bark, meconic acid, ferrous sulphide, and iron filings have been proposed, all of which have the property of decomposing corrosive sublimate. The ferrous sulphide was found quite successful by Mialhe in experiments upon dogs, if given immediately after the poison was swallowed, but failed when delayed for ten minutes.

Buckler made some successful experiments on lower animals upon the antidotal properties of a mixture of gold dust and iron filings (*Med. and Surg. Journ.*, 1843), and a case of poisoning by corrosive sublimate has been recorded by C. Johnston of Baltimore, in which this antidote was employed with the apparent result of saving life, after albumin had been used without effect. Johnston, however, employed the reduced iron of the Pharmacopœia, and gold leaf, arranging them in alternate layers, so as to make boluses of convenient size (*Am. J. M. S.*, April, 1863). The method of operation of this antidote will be understood when the action of gold and iron as a test for corrosive sublimate is explained in the succeeding paragraph. It is of the utmost importance that whatever antidote is used should be given without delay, and in this respect the one nearest at hand may be considered the best. Under all circumstances the stomach should be rapidly and thoroughly washed out by abundance of mucilaginous fluids, the stomach tube being used if necessary. The after effects should be treated like other forms of toxic gastro-enteritis, *i.e.*, by local bloodletting or counter-irritation, demulcent drinks, opiates, etc.

Tests for Corrosive Sublimate.—On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations. The best tests for determining its mercurial nature, mentioned in the order

of their delicacy, are potassium ferrocyanide, lime water, potassium carbonate, potassium iodide, ammonia, hydrogen sulphide, and stannous chloride. *Potassium ferrocyanide* gives rise to a white precipitate (mercuric ferrocyanide), becoming slowly yellowish, and at length pale blue. *Lime water* throws down a yellow precipitate of hydrated mercuric oxide. *Potassium carbonate* causes a brick-red precipitate of mercuric carbonate. *Potassium iodide* produces a very characteristic pale scarlet precipitate of mercuric iodide. This precipitate frequently appears at first yellow, especially if the corrosive sublimate be present in minute proportion. *Ammonia* gives rise to a white, flocculent precipitate, the official ammoniated mercury, or white precipitate. *Hydrogen sulphide* occasions a black precipitate of mercuric sulphide; and the same precipitate is thrown down by ammonium sulphhydrate. Finally, *tin protochloride* (stannous chloride) causes a grayish-black precipitate (mercury in a finely divided state). Taking the results of Devergie, the relative delicacy of these tests may be expressed on the basis of 100 as follows: potassium ferrocyanide 1½; lime water 4; potassium carbonate 7; potassium iodide 8; ammonia 36; hydrogen sulphide or ammonium sulphhydrate 60; and stannous chloride 80.

Wormley (*Micro-Chemistry of Poisons*, 2d ed. p. 348) states that the reaction of stannous chloride is retarded or entirely prevented by alkaline chlorates, and by free nitric acid. He highly commends, however, the following copper test: a *bright copper plate*, immersed in a solution containing corrosive sublimate, is instantly tarnished, and, after half an hour, becomes covered with a grayish-white powder; conclusive proof of mercury is obtained by heating the well-dried coated copper plate in an ignition tube, whereby the mercury is volatilized and collects in globules. A *polished piece of gold*, moistened with the clear mercurial solution, and touched through the liquid with a piece of iron, contracts a white stain. This test, proposed by Sylvester and simplified by Paris, is conveniently applied by moistening with the suspected solution a gold coin or ring, and touching it through the moistened spot with the point of a penknife. The iron forms with the gold a simple galvanic couple, which enables the latter to precipitate mercury on its surface. Nearly all the above tests merely prove the presence of mercury. To determine whether the metal is united with chlorine, the mercurial liquid may be precipitated by lime water, and the filtered solution, acidulated with nitric acid, then tested with silver nitrate. If the mercury is in the state of chloride, the filtered solution will be one of calcium chloride, which with silver nitrate will yield a heavy, white precipitate (silver chloride), insoluble in nitric acid, but soluble in ammonia; the silver nitrate may be added directly to the mercurial liquid, and, if it contains corrosive sublimate, silver chloride will fall, but probably mixed with calomel.

By the combined indications of the foregoing tests, corrosive sublimate may be infallibly detected, unless it exists in very minute quantity, associated with organic substances, by which its presence is often greatly obscured. When it exists in organic mixtures, made by boiling the contents or substance of the stomach in distilled water, Christison recommends that a preliminary trial be made with stannous chloride on a small portion filtered for the purpose. If this causes a grayish-black color, he shakes the mixture, as recommended by Orfila, with a fourth of its bulk of cold ether, which dissolves the corrosive sublimate and rises to the surface. The ethereal solution is then evaporated to dryness, and the dry salt obtained is dissolved in hot water, whereby a pure solution is procured, in which the poison may be readily detected by the ordinary tests.

In using ether, however, it must be borne in mind that, as ascertained by Mialhe, the presence of a considerable quantity of mercuric oxide, and of a chloride of an alkaline metal, prevents the solvent power of ether. If the trial test should produce a light-gray color, the corrosive sublimate is indicated in still less quantity, and Christison recommends to proceed in the following manner. Treat the unfiltered mixture with stannous chloride, as long as any precipitate is formed, which will have a slate-gray color. Collect, wash, and drain it on a filter, and, having removed it without being dried, boil it, in a glass flask, with a moderately strong solution of potassium hydroxide, until all the lumps disappear. The alkali will dissolve all animal and vegetable matter; and, on allowing the solution to remain at rest, a heavy grayish-black powder will subside, which consists chiefly of metallic mercury, and in which small globules of the metal may sometimes be seen with the naked eye, or by the aid of a magnifier. Wormley (*loc. cit.*) suggests boiling the organic mixture with water acidulated with hydrochloric acid, and testing the filtered solution with a strip of copper foil. Probably advantage might be derived from the process of dialysis, in separating corrosive sublimate, among other crystallizable substances, from the colloidal matters, contained in organic mixtures. (See *Dialysis*.)

"It should contain not less than 99.5 percent. of pure Mercurous Chloride, and be kept

in dark amber-colored bottles." U. S. "A salt, Hg_2Cl_2 , obtained as a sublimate when a mixture of mercurous sulphate and sodium chloride is heated." Br.

Hydrargyri Subchloridum, Br. Calomelas; Hydrargyri Chloridum, Hydrargyrum Chloratum (Muriaticum), Mercurius Dulcis, Chloruretum Hydrargyrosi; Mild Chloride of Mercury, Submuriate of Mercury; Chlorure Mercureux, Fr. Cod.; Protochlorure ou Sous-muriate de Mercure, Calomel, Fr.; Hydrargyrum Chloratum, P. G.; Quecksilberchlorid, G.; Protocloruro di mercurio, It.; Clesuro mercurioso sublimado, Sp.

Very properly, processes for this compound have been omitted from the Pharmacopœias, as it cannot be made by the pharmacist conveniently. For processes of the U. S. P. 1870 and of the Br. Pharm. 1885, with remarks, see foot-note.¹

Preparation on the Large Scale.—The process for making calomel by means of mercuric

¹ "Take of Mercury forty-eight troyounces; Sulphuric Acid thirty-six troyounces; Chloride of Sodium eighteen troyounces; Distilled Water, a sufficient quantity. Boil, by means of a sand-bath, twenty-four troyounces of the Mercury with the Sulphuric Acid, until a dry white mass is left. Rub this, when cold, with the remainder of the Mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the Chloride of Sodium, and, having rubbed it with the other ingredients until globules of Mercury cease to be visible, sublime the mixture into a large chamber so that the sublimate may fall in powder. Wash the sublimed matter with boiling Distilled Water, until the washings afford no precipitate with water of ammonia, and dry it." U. S. 1870.

"Take of Persulphate of Mercury ten ounces [avoirdupois]; Mercury seven ounces [av.]; Chloride of Sodium, dried, five ounces [av.]; Boiling Distilled Water a sufficiency. Moisten the Persulphate of Mercury with some of the Water, and rub it and the mercury together until globules are no longer visible; add the Chloride of Sodium, and thoroughly mix the whole by continued trituration. Sublime by a suitable apparatus into a chamber of such size that the Calomel, instead of adhering to its sides as a crystalline crust, shall fall as a fine powder on its floor. Wash this powder with boiling Distilled Water, until the washings cease to be darkened by a drop of sulphhydrate of ammonium. Finally, dry at a temperature not exceeding 212° F. (100° C.)." Br. 1885.

In the U. S. process, 1870, as in the case of corrosive sublimate, mercuric sulphate is first formed; but, instead of being immediately sublimed with the sodium chloride, it undergoes a preparatory trituration with a quantity of mercury equal to that employed in forming it. The residue of this process and of that for corrosive sublimate are the same. The calomel, as sublimed, is liable to contain a little corrosive sublimate; and hence the direction of the U. S. Pharmacopœia of 1870 to wash it with boiling distilled water until ammonia produces no precipitate with the washings. According to Berthé, calomel in contact with hot water is converted, to a small extent, into corrosive sublimate; hence he recommends that the portion of water to be tested should be cold when passed through the calomel. The British process (1885) is a modification of that of the old Dublin Pharmacopœia, including, like that, no directions for making the mercuric sulphate, because this salt is made by a separate formula, being designated as *persulphate of mercury*. It omits, however, as unnecessary, a partial preliminary sublimation, to test the production of corrosive sublimate, and, immediately after a thorough mixture of the materials, proceeds to the final sublimation. An improvement was to cause the vapors to enter for condensation a chamber of considerable size, so that they might fall in powder, instead of condensing on the sides of the receiver in a crystalline mass. The necessity of pulverizing the calomel is thus avoided. The Br. Pharmacopœia (1885) directs the powder to be washed, but, instead of using ammonia as a test of the absence of corrosive sublimate in the washings, directs for the purpose ammonium sulphide, which throws down a black precipitate if corrosive sublimate be present.

sulphate was originally practised at Apothecaries' Hall, London. The proportions taken and the mode of proceeding in that establishment were, according to Brande, as follows: 50 lbs. of mercury are boiled to dryness with 70 lbs. of sulphuric acid, in a cast iron vessel; and 62 lbs. of the dry salt formed are triturated with 40½ lbs. of mercury until the globules disappear, and the whole is mixed with 34 lbs. of sodium chloride. The mixture is sublimed from an earthenware retort into an earthenware receiver, and the product is from 95 to 100 lbs. of calomel in mass. This is then ground to an impalpable powder, and washed with a large quantity of distilled water.

To bring the calomel into a state of minute division the method of Joseph Jewell of London, improved by Ossian Henry, is employed. It consists in causing the calomel in vapor to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury*, is free from all suspicion of containing corrosive sublimate, is much finer than when obtained by levigation and elutriation, and possesses more activity as a medicine. This kind of calomel is included in the French Codex under a distinct name (*Mercur doux à la vapeur*). Soubeiran of Paris, has perfected a process for obtaining calomel as an impalpable powder, by substituting the agency of cold air for that of steam for the purpose of condensing it; this process he believes to be precisely the same as that pursued by the English manufacturers, producing a calomel equal to the best English. A description of his apparatus may be found in the *J. P. C.* (3e sér., ii.), and of the English apparatus, as described by F. C. Calvert, in the same journal (3e sér., iii.). Both these papers are copied into the *A. J. P.* (xv.).

Calomel may also be prepared in the dry way by taking four parts of corrosive sublimate and rubbing it up in a mortar with three parts of mercury, after moistening the mass with alcohol. The powder is then dried and sublimed in glass flasks. The powder should be dried quickly before sublimation, so as to drive off any trace of uncombined mercury. A comparative examination of English and American calomel was undertaken separately in 1885 by Bedford and Patch. (See *Proc. A. Ph. A.*, 1885.) While there was no reason for preferring English calomel, none of the samples exhibited more than traces of mercuric chloride. Wöhler has proposed to obtain calomel, in the humid way, by precipitating a solution of corrosive sublimate by a stream of sulphurous acid, taking advantage of a reaction first observed by Vogel. Calomel obtained in the humid way, called *precipitated calomel*, was formerly official with the Dublin College, and was adopted in the French Codex. This form of calomel is of doubtful utility, and when

obtained by Wöhler's process it is a crystalline powder, which is unfit for use unless after elaborate levigation and elutriation.

Properties.—When in mass, its form and appearance depend on the shape and temperature of the subliming vessel. In this state it is generally in the form of a white, fibrous, crystalline cake, the interior of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7.2. Patch found (*Proc. A. Ph. A.*, 1885, p. 477) the sp. gr. of calomel to vary from 6.94 to 7.93, the standard being water at 39° F. Powder is the official form of this chloride, in which state it is always kept by pharmacists. The powder has a light buff or ivory color, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, as is the case with Jewell's calomel and in the official processes, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black or covered with black paper. By the action of the fixed alkalies or alkaline earths it immediately becomes black, in consequence of the formation of mercurous oxide, reducible by heat to the metallic state. The preparation employed under the name of *lotio nigra*, or *black wash*, as a local application to syphilitic ulcers, etc., is made by adding a *drachm* of calomel to a *pint* of lime water. (See *Lotio Nigra*.) By double decomposition between the calomel and lime, the black suboxide precipitates, and calcium chloride remains in solution, indicated by yielding a copious white precipitate with silver nitrate. The oxide, however, is not pure, but associated with undecomposed calomel. Before being applied, the wash should be well shaken.

It is officially described as "a white, impalpable powder, becoming yellowish-white on being triturated with strong pressure, and showing only small, isolated crystals when viewed under a lens having a magnifying power of one hundred diameters. It is odorless and tasteless, and permanent in the air. Insoluble in water, alcohol, or ether, and also in cold dilute acids. When strongly heated, Mercurous Chloride is volatilized without fusion or the evolution of brown vapors, leaving no appreciable residue. In contact with calcium hydroxide T.S., or with solutions of alkali hydroxides, or with ammonia water, the salt is blackened. When heated with dried sodium carbonate in a dry glass tube, it yields a sublimate of metallic mercury." *U. S.*

Tests.—Calomel, when pure, completely sublimes on the application of heat, a property which detects all fixed impurities, such as calcium carbonate, sulphate, and phosphate, barium sulphate, and lead carbonate. Under the influence of an elevated temperature, especially in the presence of alcohol or water, it gives

rise to a small quantity of corrosive sublimate. (Berthé.) Calomel strikes a black color, free from reddish tinge, by the action of the fixed alkalies, and the black oxide thus produced is brought by heat to the metallic state. The buff color indicates the absence of corrosive sublimate, but whiteness by no means shows the presence of this impurity. Its freedom from the corrosive chloride may be determined by washing a portion of it in warm distilled water, and then testing the water with ammonia, which will cause a white precipitate (ammoniated mercury) should the water have taken up any of the poisonous chloride.

The official tests are as follows: "If 1 Gm. of the salt be shaken with 10 Cc. of water or alcohol, and the mixture filtered, neither of the filtrates should respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121), nor should any appreciable residue be left on evaporation (absence of *soluble impurities*). If 2 Gm. of the salt be shaken with 20 Cc. of ether, filtered, the filtrate evaporated, and 10 Cc. of distilled water added, not more than a slight opalescence should result upon the addition of silver nitrate T.S. to 5 Cc. of the filtrate, and no change in color should be produced upon adding a few drops of ammonium sulphide T.S. to the remainder (absence of *mercuric chloride*). On heating a portion of the salt in a test-tube with potassium hydroxide T.S., it should not evolve ammonia; and if another portion be shaken with acetic acid, and filtered, the filtrate should not be affected by hydrogen sulphide T.S., nor by silver nitrate T.S. (distinction from, and absence of, *ammoniated mercury*). If to 0.5 Gm. of Mercurous Chloride contained in a small beaker, 5 Cc. of nitric acid be added, and the mixture evaporated to dryness on a water-bath, and if, after dissolving the residue in about 25 Cc. of distilled water and 5 Cc. of hydrochloric acid, the solution be completely saturated with hydrogen sulphide, and allowed to stand for several hours in a well-corked flask, until the precipitate has subsided, and then filtered, the filtrate should be colorless and leave no weighable residue upon evaporation (absence of many *foreign salts*). If the precipitate obtained in the preceding test, after washing with about 100 Cc. of water, and draining, be rinsed into a beaker with about 20 Cc. of water and then 5 Cc. of stronger ammonia water added, and if, after covering and digesting the mixture for about 15 minutes on a water-bath, it be rinsed upon a filter and washed with a little water, the filtrate and washings, after evaporating to dryness, moistening with 6 drops of nitric acid, and again drying, should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). If the precipitated sulphide remaining upon the filter be treated with diluted nitric acid (1 in 4), warmed, and then filtered, the filtrate should leave no weighable residue upon evaporation and gentle ignition (limit of *foreign*

metals)." U. S. "A dull-white heavy and nearly tasteless powder, sometimes rendered yellowish by prolonged trituration; insoluble in water, alcohol (90 per cent.), or ether. It affords the reactions characteristic of mercurous salts and of chlorides. Hydrocyanic acid converts it into mercuric salt and a black powder readily yielding metallic mercury. It volatilizes when sufficiently heated, leaving only a trace of fixed residue. Warm ether with which it has been shaken leaves, on evaporation, no residue (absence of mercuric chloride). Warmed with solution of potassium hydroxide it becomes black and does not evolve ammonia (absence of mercuric-ammonium chloride). When heated with excess of lime it should yield 84.4 to 84.9 per cent. of metallic mercury." Br.

An easy method of detecting corrosive sublimate, proposed by Bonnewyn, is to put some of the suspected powder upon a well polished surface of iron, and then moisten it with a drop of alcohol or ether. If the calomel be pure the surface will remain quite unaffected, while it will be blackened by corrosive sublimate if present in the proportion of only one to 50,000 (*J. P. C.*, 4e sér., ii. 79). The presence of any soluble chloride whatever in the calomel would be detected by the production of a precipitate with the washing by silver nitrate. Soluble salts of mercury may be detected by rubbing the suspected calomel with ether on a bright surface of copper, when the metal will become amalgamated and exhibit a white stain. When this test shows impurity, the soluble salt present is probably corrosive sublimate. Calomel containing corrosive sublimate acts violently on the bowels, and, when the impurity has been present in considerable amount, has been known to cause death. Besides being incompatible with the alkalies and alkaline earths, calomel is also decomposed by the alkaline carbonates, soaps, sulphhydrates, and, according to some authorities, by iron, lead, and copper. By boiling with the alkaline formates it is decomposed, and metallic mercury liberated. (H. Rose, *Annal. der Physik und Chem.*, cvi. 500.)

According to Lebeaux, calomel should not be prescribed with iodine, unless the prescriber intends to give mercuric iodide (red iodide), when the dose must be reduced accordingly. (*Ann. Thér.*, 1857, p. 180.) It should not be given at the same time with nitrohydrochloric acid, for fear of generating corrosive sublimate. One of the authors has been informed of a case in which death, with symptoms of violent gastro-intestinal irritation, followed their joint use. According to the experiments of Deschamps, calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, mercuric cyanide, and ammonium chloride are formed; in the latter, corrosive sublimate and mercuric cyanide only; hence this writer considers it very dangerous to associate calomel with bitter almonds or hydrocyanic acid in prescription. This con-

clusion has been confirmed by Mialhe and Preneloup, and more recently it has been shown by E. Riegel that cherry-laurel water has the power of converting calomel into corrosive sublimate. According to Mialhe, calomel is in part converted into corrosive sublimate and metallic mercury by ammonium chloride and by sodium and potassium chlorides, even at the temperature of the body; hence he believes that the conversion may take place in the *primæ viæ*. Popular belief coincides with Mialhe's views in regard to the power of common salt to increase the activity of calomel.

Uses.—Calomel unites to the general properties of the mercurials those of a purgative and anthelmintic. It is the most valuable of the mercurial preparations. Whether the object is to bring the system under the general influence of mercury, or to produce its alterative action upon the hepatic or other secretory function, calomel, on account both of its certainty and of its mildness, is preferred to all other preparations, with the single exception of the blue pill, which, though less certain, is still milder, and is sometimes preferably employed. When used with the above objects, the tendency to purge which it sometimes evinces, even in very small doses, must be restrained by combining it with opium. As a purgative, calomel owes its chief value to its tendency to act on the liver, the secretory function of which it stimulates. It is usually slow and somewhat uncertain in its cathartic effect, and, though itself but slightly irritating, sometimes occasions severe griping pain with bilious vomiting, attributable to the acrid character of the bile which it causes the liver to secrete.

It is peculiarly useful in the commencement of bilious fevers, in hepatitis, jaundice, bilious and painter's colic, dysentery, especially that of tropical climates, and all other affections attended with congestion of the portal system or torpidity of the hepatic function. The difficulty with which it is thrown from the stomach renders it highly useful in some cases of obstinate vomiting, when other remedies are rejected. In the case of children it is peculiarly valuable from the facility of its administration. In the treatment of worms it is often useful as an aid to other remedies, acting probably not only as a purgative, but also as an irritant to the worms, either by its immediate influence or that of the acrid bile which it causes to flow. The slowness and uncertainty of its action, and its liability to salivate if too long retained in the bowels, render it proper either to follow or combine it with other cathartics, in order to insure its purgative effect. When given alone, it should be followed, if it does not operate in six or seven hours, by a dose of castor oil or magnesium citrate. The cathartics with which it is most frequently combined are jalap, rhubarb, aloes, scammony, colocynth, and gamboge. It is often added in small quantities to purgative combinations, with a view to its influence on the liver.

In very large doses, calomel is supposed by some to act directly as a sedative, and with this view has been given in *yellow and malignant bilious fevers*, violent *dysentery*, malignant *cholera*, etc. The quantities which have been administered in such affections, with asserted impunity and even advantage, are almost incredible. A common dose is twenty or forty grains, repeated every half hour, or hour, or less frequently, according to the circumstances of the case. It is unquestionable that the effects obtained from calomel are not at all proportionate to the size of the dose. This is evidently due to the peculiarities of its absorption. It seems to be established that it is not, as was at one time supposed, converted in the stomach into corrosive sublimate, but is precipitated by the alkaline juices of the intestine in the form of black oxide, which black oxide is itself soluble in alkaline liquors and also in fatty matters. A small quantity of calomel coming into the intestines is, therefore, at once converted into black oxide and fully exhausts all the solvent power of the alkaline juices, which may therefore be unable to take up any more rapidly a large than a small amount of the drug. It is possible that in some cases in which minute doses of calomel are given in powdered form, the excessive action of the drug is due to the conversion of part of the calomel into corrosive sublimate.¹

Externally applied, calomel is often used as an efficient alterative and desiccant in venereal and other *ulcers*, herpetic eruptions, etc.

In *syphilis*, calomel vapor baths once or twice a week are often of service. They may be made extemporaneously by pouring an ounce and a half of water into a dish, putting twenty grains of calomel in it, and heating by means of a spirit lamp, the patient being seated on a chair over the dish, and surrounded by blankets closely wrapped around the neck, spread out below.

Dose, as an alternative, in functional derangement of the liver, is from half a grain to a grain (0.032 to 0.065 Gm.) every night, or every other night, followed in the morning,

if the bowels are not opened, by a gentle saline laxative. When the stomach or bowels are very irritable, as in cholera and diarrhoea, from an eighth to a quarter of a grain (0.008 to 0.016 Gm.) may be given every hour or two, so as to amount to one or two grains (0.065 to 0.13 Gm.) in the course of the day. With a view to salivation, the dose is from half a grain to a grain (0.032 to 0.065 Gm.) three or four times a day, to be increased considerably in urgent cases. Sometimes very minute doses, as the twelfth of a grain (0.005 Gm.) or less, given very frequently, so as to amount to the ordinary quantity in twenty-four hours, will operate more effectually as a sialagogue than larger doses. When large doses are given with this view, it is often necessary to combine them with opium. As a purgative, from five to fifteen grains (0.32 to 1 Gm.) or more may be exhibited. The cathartic action is not increased in proportion to the dose, and enormous quantities have been given with impunity. On the other hand, the most effective method of influencing the liver and other intestinal glands, is the exhibition of one-fourth to one-half grain (0.016 to 0.032 Gm.) doses every hour, until the effect is produced or five or six grains (0.32 or 0.4 Gm.) have been taken. Even in very small single doses of not more than one, two, or three grains (0.065, 0.13, or 0.20 Gm.), calomel purges some individuals briskly. In these persons, large doses, though they do not proportionally increase the evacuation, often occasion spasmodic pain in the stomach and bowels. For children larger doses are generally required in proportion than for adults. Not less than from two to three grains (0.13 to 0.20 Gm.) should be given as a purge to a child two or three years old, and this quantity often fails to act, unless assisted by castor oil or some other cathartic. Calomel may be given in pill made with gum arabic and syrup, or in powder mixed with syrup or molasses.

¹ G. Vulpius has investigated the conditions which favor the formation of corrosive sublimate in calomel mixtures, and reaches the following conclusions:

1. No sublimate forms in the course of twenty-four hours in mixtures of calomel with white sugar, milk sugar, magnesia, magnesium carbonate, and sodium bicarbonate.

2. No such formation takes place in three months in mixtures of calomel with magnesia, magnesium carbonate, and sugar.

3. Minute traces of corrosive sublimate are found at the expiration of the same time in a mixture of calomel, sodium bicarbonate, and sugar of milk.

4. A large quantity of corrosive-sublimate forms in the same time in a mixture of calomel, sodium bicarbonate, and cane sugar.

5. Calomel powders containing magnesia or sodium bicarbonate alone will contain corrosive sublimate if digested with water.

6. The formation of corrosive sublimate in mixtures of calomel and alkalis digested in water for a short time is not favored, but, on the contrary, prevented, by the presence of hydrochloric acid in the water, the acid neutralizing, to a certain extent, the alkalis which cause the formation. (A. J. P., 1879.)

* "Mercury, *fifty grammes* [or 1 ounce av., 334 grains]; Nitric Acid, Potassium Iodide, Distilled Water, each, a *sufficient quantity*. Mix *twenty cubic centimeters* [or 325 minims], each, of Nitric Acid and Distilled Water, and, when the liquid is cold, pour it upon the Mercury contained in a glass beaker. Set the mixture aside in a dark place, and keep it at a temperature between 25° and 30° C. (77° and 86° F.), with occasional agitation, until the reaction ceases and a little mercury still remains undissolved. Separate the crystals of mercurous nitrate, which will have formed, from the mother-liquid, allow them to drain in a glass funnel, and dry them on bibulous paper, in a dark place. When the salt is dry dissolve *forty grammes* [or 1 ounce av., 180 grains] of it in *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Distilled Water to which *six cubic centimeters* [or 97 minims] of Nitric Acid have previously been added. Having prepared a solution of *sixteen grammes* [or 247 grains] of Potassium Iodide in *thirty-two cubic centimeters* [or 1 fluidounce, 39 minims] of Distilled Water, slowly pour the solution of Potassium Iodide into the solution of Mercurous Nitrate, with constant stirring, which should be continued for fifteen minutes, allow the precipitate to subside, decant the supernatant liquid, and wash the precipitate by decantation with ten successive portions of *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] each of Distilled Water. Finally, transfer the precipitate to a filter, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 40° C. (104° F.), and keep it in dark amber-colored vials, with the least possible exposure to light. Instead of weighing off *forty grammes* [or 1 ounce av., 180 grains] of the Mercurous Nitrate as above directed, the whole of the crystallized salt may be taken and the amount of Potassium Iodide, etc., adjusted to the proportions given above." *U. S.*

The Br. Pharm. dropped this salt at its 1885 revision, and did not restore it in 1898, and the omission has been rather severely criticised.

The process of the U. S. P. (8th Rev.) for this salt differs from that official in 1880¹ for green iodide of mercury; it is essentially the process

recommended by Edward Soetje (*Proc. A. Ph. A.*, 1888, p. 167), the product is the result of double decomposition between mercurous nitrate and potassium iodide, in solution, yellow mercurous iodide and potassium nitrate being formed. This method of making mercurous iodide has long been known, but the disadvantage heretofore has been that some mercuric iodide was formed, which contaminated the product; the thorough washing by ten successive portions of distilled water should remove all traces of this impurity. Several other methods of making mercurous iodide have been proposed. Roland Seeger suggests double decomposition between mercurous acetate and potassium iodide. (*A. J. P.*, 1859, p. 204.) Boutigny proposes to decompose calomel by potassium iodide, and gives the following formula. Twenty-nine drachms of calomel are mixed with twenty drachms of pulverized potassium iodide in a glass mortar, and twelve ounces of boiling distilled water poured upon the mixture. After cooling the liquid is decanted, and the precipitate washed on a filter with distilled water, and dried in the shade. (See *A. J. P.*, viii. 326.) This process was not successful with Charles Bullock, when he used the reacting ingredients in quantities six times those recommended by Boutigny. John Canavan of New York, ascribes the failure to insufficient trituration, which, to insure complete reaction, must be long continued. If the reaction be imperfect, the water washes away not only potassium chloride, but also potassium iodide, holding in solution a part of mercurous iodide formed, which is ultimately decomposed into mercuric iodide and metallic mercury. The experiments of Maisch tend to confirm this view. He further found that a boiling temperature enables potassium chloride to decompose the mercurous iodide perceptibly, and infers that the use of cold water would give a purer product. He therefore concludes that the process of Boutigny cannot be depended upon for giving a pure mercurous iodide.

P. Yvon has prepared mercurous iodide by subliming iodine with an excess of mercury, and subsequently washing it with diluted nitric acid. (*J. P. C.*, 4e sér., xviii. p. 167.) George A. Haffa precipitated a solution of mercurous nitrate with potassium iodide, and obtained mercurous iodide of a yellow or green color according to the density of the solution. The solution of mercurous nitrate is prepared by acting upon 15,000 gr. of mercury with a cold mixture of nitric acid (6000 gr.) and water (4000 gr.), placing the vessel in cold water, and stirring the contents constantly until the reaction has entirely ceased; the white crystalline mass, without being separated from

¹ *Hydrargyri Iodidum Viride*, U. S. 1880.—"Mercury, *eight parts* [or one ounce av.]; Iodine, *five parts* [or two hundred and seventy-four grains]; Alcohol, a *sufficient quantity*. Pour about *three parts* [or half a fluidounce] of Alcohol into a mortar containing the Mercury, add the Iodine in several successive portions, and triturate the mixture, adding sufficient Alcohol from time to time to keep the mass constantly moist, and taking care that it shall neither become too hot, nor be exposed to light during the various steps of the process. Continue the trituration until all globules of Mercury have disappeared and the mixture has become nearly dry and has acquired a greenish-yellow color. Then add sufficient Alcohol to reduce the whole to a thin paste, pour this into a bottle, let it stand for several days, and then wash the Iodide twice with about *fifty parts* [or half a pint] of Alcohol each time, and decant the washings. Transfer the Iodide to a filter and continue washing with Alcohol until the washings are no longer affected by hydrosulphuric acid.

Lastly, dry the product in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stopped bottles, protected from light." *U. S.* 1880. This process for forming the mercurous iodide is a case of simple combination, the alcohol facilitating the union by dissolving the iodine.

the excess of metallic mercury, is then dissolved in water acidulated with nitric acid (1 oz. to the gallon) until the solution measures four pints. For preparing *green mercurous iodide*, six ounces of a solution of mercurous nitrate are mixed with six pints of water, and there is added in a continuous stream, and with constant stirring, a solution of potassium iodide (3 oz. in 54 oz. of water); the precipitate is washed with water, and dried without the aid of heat. *Yellow mercurous iodide* is prepared in the same manner, except that two ounces of solution of mercurous nitrate diluted with water (8 pints) are used with a solution of potassium iodide (1 oz. in 4 pints of water). This salt darkens much more quickly when exposed to the light than that made by the U. S. P. 1880 process. (*A. J. P.*, 1886.) Stömen practically confirms these results. (*Ber. d. Chem. Ges.*, 1887; see also *Ph. Era*, 1888.) From experiments by C. H. Wood, it appears that the green iodide is a mixture of yellow iodide and metallic mercury. By continuing the trituration, the powders become more and more yellow, and at length have only a tinge of green. He infers that pure mercurous iodide is yellow, and that the green color is owing to an admixture of the blue of the mercury with the yellow of the mercurous iodide.¹ (*P. J.*, 1868.) Flückiger (*Pharmaceutische Chemie*, 2d ed., 1888) agrees with this view, and says that by slow sublimation, at a very gentle heat, the true mercurous iodide can be obtained in small transparent yellow crystals of the quadratic system which are related to the forms of calomel. (See *J. P. C.*, 1894, 67.) Francoeur's process is essentially the result of the reducing action of aldehyde on iodo-mercurammonium iodide. (*J. P. C.*, 1894, 67.)

Properties.—It is officially described as "a bright yellow, amorphous powder, odorless and tasteless. By exposure to light it becomes darker, in proportion as it undergoes decomposition into metallic mercury and mercuric iodide. Almost insoluble in water, and wholly insoluble in alcohol or ether. When slowly and moderately heated, it assumes at first an orange and then a red color, becoming yellow again on cooling. When quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is volatilized, leaving not more than 0.05 percent. of residue. When Mercurous Iodide is heated with sulphuric acid and a little manganese dioxide, vapor of iodine is evolved. In contact with a solution of

potassium iodide, the salt is decomposed into mercuric iodide, which dissolves, and metallic mercury, which remains undissolved. If 0.5 Gm. of the salt be shaken with 10 Cc. of alcohol and the mixture allowed to stand and then filtered, a portion of the perfectly clear filtrate should be scarcely affected by hydrogen sulphide T.S., nor should it produce more than a very faint, transient opalescence when dropped into water; and if 5 Cc. of the filtrate be evaporated on a white porcelain surface, not more than a very faint, red stain should remain (absence of more than traces of *mercuric iodide*)." *U. S.* Its sp. gr. is 7.75. If quickly and cautiously heated, it sublimes in red crystals, which afterwards become yellow. "Gradually heated in a test-tube, it yields a yellow sublimate, which, upon friction, or after cooling, becomes red, while globules of metallic mercury are left in the bottom of the tube." *Br.* 1867. It is sometimes considered to be composed of two atoms of mercury united with two atoms of iodine, Hg_2I_2 , $397 + 251.8 = 648.8$, although most chemists and the present *U. S. P.* make its formula HgI , consisting of one atom of mercury 198.50, and one of iodine 125.9 = 324.40. (See *Chem. News*, 1896, 12, 95, 306.)

Uses.—Mercurous iodide is used in advanced *syphilis*. The dose is one-fifth of a grain (0.012 Gm.), gradually increased to two grains (0.13 Gm.). It should never be given at the same time with potassium iodide, which converts it into mercuric iodide and metallic mercury.

Dose, one-fifth of a grain (0.012 Gm.).

* "Corrosive Mercuric Chloride, *forty grammes* [or 1 ounce av., 180 grains]; Potassium Iodide, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *a sufficient quantity*. Dissolve the Corrosive Mercuric Chloride and the Potassium Iodide, each, in *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Distilled Water, and filter the solutions separately. Pour both solutions, simultaneously and in a thin stream, with constant and very active stirring, into two thousand

¹ Patrouillard recommends Dublanc's process, which consists in triturating together a mixture of mercuric (red) iodide and of metallic mercury, in the following proportions: mercuric iodide 227 parts; mercury 100 parts. The mercuric iodide may easily be obtained of absolute purity and in a state of perfect dryness; besides, during the trituration there is no risk of loss by volatilization. The mixture should merely be moistened with alcohol of eighty per cent., so as to form a thin paste, and well triturated; the reaction takes place in a very short time, and the product is of a dark greenish-yellow color. By way of precaution, it should be washed with boiling alcohol. (*Rép. de Pharm.*, 1877, 549; *N. R.*, Nov. 1877.)

cubic centimeters [or 67 fluidounces, 5 fluidrachms] of Distilled Water. When the precipitate has subsided, decant the supernatant liquid, collect the precipitate on a filter, and wash it with cold Distilled Water, until the washings give not more than a slight opalescence with silver nitrate test solution. Finally, dry it in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.), and keep it in well-stoppered bottles, protected from light." *U. S.*

In the above process for forming mercuric iodide a double decomposition takes place between corrosive sublimate and potassium iodide, resulting in the formation of potassium chloride which remains in solution, and mercuric iodide which precipitates. The precipitate is soluble in the reacting salts, and hence a loss of part of it is incurred by an excess of either. It is best, however, to have a slight excess of the potassium iodide, which is furnished by the proportion taken in the formula, as then decomposition of the whole of the corrosive sublimate is insured, and any contamination of the mercuric iodide by it prevented; loss by solution in the supernatant liquid is largely obviated by the improvement which was first introduced in the U. S. P. 1890, whereby separate solutions are poured simultaneously into a large volume of water. The process of the Edinburgh College consisted in a combination of the ingredients by trituration in due proportion with the aid of alcohol; but after the red powder was obtained it was treated with a boiling solution of sodium chloride, which dissolved the mercuric iodide to the exclusion of any contaminating mercurous iodide, and the solution thus obtained, on cooling, deposited the pure mercuric salt in crystals. F. R. Williams states that in the manufacture of the red iodide on a large scale the amount of water required by the official processes is very troublesome. He remedies it by using ammonium chloride, so as to get a very concentrated solution of corrosive sublimate, which he adds to a concentrated solution of the iodide. The addition of the ammonium chloride does not interfere with the reaction, but is of material service in assisting in the solution of the corrosive sublimate. (*P. J.*, June, 1873.)

Chas. L. Mitchell has improved upon the process of Williams; see foot-note.¹

Properties.—As obtained by the late Edinburgh process, it is in splendid crimson acicular

crystals. Köhler has found, however, that it crystallizes better from boiling hydrochloric acid. (*Ber. d. Chem. Ges.*, 1879, p. 608.) It also crystallizes well from hot saturated solutions in acetone, glacial acetic acid, absolute alcohol, amyl alcohol, and nitric acid of 1.2 sp. gr., see also *Chem. News*, 1900, 24. When heated the mass becomes yellow at about 150° C. (302° F.), melting at 254° C. (489.2° F.) to a dark yellow liquid, and sublimes at 349° C. in yellow rhombic scales, which become red on cooling. Mercuric iodide is a dimorphous substance, having a different crystalline form in its red and yellow states. According to Schiff, it is only in its yellow form that it is soluble in alcohol; hence it is that, when separated by water from its alcoholic solution, it falls in this condition. (*Ann. Ch. Ph.*, cix. 371.) It forms definite compounds with the iodides of the alkali metals. The compound formed with potassium iodide has been used as a medicine. (See *Potassium Iodohydrargyrate*, in PART II.) "When digested with solution of soda it assumes a reddish-brown color, and the fluid, cleared by filtration and mixed with solution of starch, gives a blue precipitate on being acidulated with nitric acid," showing that it is an iodide. Mercuric iodide consists of one atom of mercury 198.5, and two atoms of iodine 251.80 = 450.30, and its formula is HgI_2 . It combines with mercurous iodide, so as to form a yellow sesqui-iodide, represented by the formula $HgI + HgI_2$, or Hg_2I_3 .

"A scarlet-red, amorphous powder, odorless and tasteless; permanent in the air. Almost insoluble in water; soluble in 116 parts of alcohol, 85 parts of ether, and 1340 parts of chloroform at 25° C. (77° F.); soluble in 15 parts of boiling alcohol; also soluble in solutions of the soluble iodides, mercuric chloride, sodium thiosulphate, and hot solutions of the alkali chlorides. When heated to about 150° C. (302° F.), the salt becomes yellow, but again assumes a red color on cooling; at 253° C. (487.4° F.) it fuses to a dark yellow liquid, which, on cooling, forms a yellow, crystalline mass, and at higher temperatures is finally volatilized, leaving no appreciable residue. On heating the salt with potassium hydroxide T.S., and adding a little sugar of milk, metallic mercury is precipitated. A saturated solution of Mercuric Iodide in hot alcohol should, after cooling, be colorless; and when diluted with an equal volume of water, the solution should not redden blue litmus paper (absence of mercuric chloride). If about 0.5 Gm. of Mercuric Iodide be thoroughly agitated with 10 Cc. of distilled water, the filtered liquid should not become more than slightly colored by hydrogen sulphide T.S., nor give more than a slight opalescence with silver nitrate T.S. (limit of soluble chlorides or iodides)." *U. S.* "A crystalline powder of a vermilion color, becoming yellow when a film of it spread on a sheet of paper is gently heated over a lamp. It is almost insoluble in water, dissolves sparingly

¹ *Hydrargyri Iodidum Rubrum, Mitchell's Process.* Mercury, 1000 gr.; Nitric Acid, 1700 gr.; Potassium Iodide, 1662 gr. or q. s.; Distilled Water, q. s. (Instead of the mercury and nitric acid, 2500 gr. of solution of mercuric nitrate can be used.) Dissolve the mercury in the nitric acid by the aid of a little heat (in large quantities this is not necessary, as the reaction between the acid and the mercury generates sufficient heat), and dilute with an equal bulk of water. Then add the potassium iodide, dissolved in eight fluidounces of water, until no further precipitation ensues, being careful towards the last to add the solution very gradually, so as to avoid dissolving the mercuric iodide in an excess of the liquid. Collect the precipitate on a filter, wash well with distilled water, drain and dry. (*A. J. P.*, 1876, 116.)

in alcohol (90 per cent.), but freely and entirely in ether (absence of mercurous iodide), or in solution of potassium iodide. It affords the reactions characteristic of mercuric compounds and of iodides. It volatilizes at a temperature under redness, leaving not more than a trace of fixed matter. When heated with excess of copper it should yield 43.5 to 44 per cent. of metallic mercury." *Br.*

Uses.—Mercuric iodide is a powerful irritant poison. It has been used in similar diseases with the mercurous iodide, namely, in *scrofula* and *syphilis*, but is much more active. It is especially valuable in old, obstinate cases of syphilis, as in syphilitic rheumatic pains and diseases of the bones, thickening of the dura mater, etc. There seems to be in these cases no practical difference between its action and that of corrosive sublimate, although sometimes it is better borne by the stomach than is the latter preparation. The dose is one-twentieth of a grain (0.003 Gm.), gradually increased to one-fourth of a grain (0.016 Gm.), given in pill. It is sometimes administered in water with potassium iodide so as to make a solution of potassio-mercuric iodide.¹ Cazenave considers mercuric iodide to be the best topical application in *lupus*. He applies it in thin layers, every six or eight days, to small portions of the ulcerated surface at a time, in the form of a caustic ointment, made of equal parts of the iodide, oil, and lard. The application produces severe pain, and gives rise to a sharp inflammation, which soon terminates, leaving the ulcer in an improved condition, with a tendency to cicatrize smoothly and on a level with the surrounding skin. A solution of mercuric iodide in olive oil (1 in 5000), which is to be prescribed as an external application, has been prepared by Delacour. (See *J. P. C.*, 1903, 603; 1904, No. 2.)

* "Corrosive Mercuric Chloride, one hundred grammes [or 3 ounces av., 231 grains]; Sodium Hydroxide, forty grammes [or 1 ounce av., 180 grains]; Distilled Water, a sufficient quantity. Dissolve the Corrosive Mercuric Chloride in one thousand cubic centimeters [or 33 fluid-ounces 6½ fluidrachms] of warm Distilled Water, and filter the solution. Dissolve the Sodium Hydroxide (which should contain at least 90 percent. of pure, anhydrous sodium hydroxide) in one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of cold Distilled Water, and into this solution pour gradually, and with constant stirring, the solution of Corrosive Mercuric Chloride. Allow the mixture to stand for an hour at a temperature of about 30° C. (86° F.), stirring frequently. Then decant the supernatant, clear liquid from the precipitate, and wash the latter repeatedly by the addition and decantation of portions of Distilled Water, using one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Water each time. Collect the precipitate on a strainer, and continue the washing with warm Distilled Water, until a small portion of the washings, when poured on a little mercuric chloride test solution, no longer produces a yellowish turbidity at the line of contact of the two liquids. Then allow the precipitate to drain, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.), and keep it in well-stoppered bottles, protected from light." *U. S.*

The process adopted for this preparation is that of Hoffmann. The United States Pharmacopœia directs the alkaline solution in excess, and the addition of the corrosive sublimate to the alkali. Both these points are important, for if the corrosive sublimate be in excess, brown oxychloride will be formed towards the last of the decomposition, and when the alkali is added to the solution of corrosive sublimate, the same compound will be formed from the first, and is with difficulty decomposed by an excess of alkali. The solution of sodium hydroxide should be as free as possible from carbonate, to prevent the formation of brown mercuric carbonate. The mercuric chloride is precipitated by the sodium hydroxide, sodium chloride being left in solution. The object of the subsequent washing is to remove the sodium chloride and the excess of the alkali.¹

¹ *Strop Gibert. Gibert's Syrup.*—A syrup has been largely used in the French hospitals and in this country which has received this name. It is made by dissolving three grains of mercuric iodide and one hundred and two grains of potassium iodide in three fluidrachms of water, filtering, and adding sufficient simple syrup to make ten fluidounces. Each tablespoonful contains about one-seventh of a grain of mercuric iodide and five grains of potassium iodide.

¹ Charles L. Mitchell proposes an improvement on the official process, which avoids the use of large vessels when it is made on a large scale. He takes of solution of mercuric nitrate (prepared by dis-

The process was improved in the 1890 revision (and the improvement retained in the 8th Rev.) through the use of a freshly made solution of sodium hydroxide; the official "solution of potassa" used in the U. S. P. 1880 process invariably contained potassium carbonate, except when it was freshly made, and the presence of carbonate gave the mercuric oxide a reddish-brown tint which was very objectionable.

Properties.—The official mercuric oxide is of a yellow color similar to that of the yolk of egg, and is a completely amorphous powder, exhibiting no evidence of crystalline particles even under the microscope. Yellow mercuric oxide differs from the red only by being amorphous and in a much more minute state of division, the red oxide by trituration acquiring an orange and finally a yellow color. In consequence of its different state of aggregation, it is much more quickly acted on by reagents than is the red oxide. Thus, oxalic acid, which acts on the red oxide only with the aid of heat, immediately combines with the yellow oxide at ordinary temperatures, producing the white oxalate, and while the latter oxide, in contact with chlorine, gives up oxygen to that element, forming hypochlorous acid and corrosive sublimate, the former exercises scarcely any influence on the gas at common temperatures. It is described in the U. S. Pharmacopœia as "a light orange-yellow, amorphous, heavy, impalpable powder; odorless, and having a somewhat metallic taste; permanent in the air, but turning darker on exposure to light. Almost insoluble in water, insoluble in alcohol, but readily and completely soluble in diluted hydrochloric or nitric acid, forming colorless solutions. When moderately heated, Yellow Mercuric Oxide assumes a red color. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving not more than 0.1 percent. of residue. When moistened with hot water, Yellow Mercuric Oxide should not turn red litmus paper blue. If 0.5 Gm. of Yellow Mercuric Oxide be digested on a water-bath, for fifteen minutes, with a solution of 1 Gm. of oxalic acid in 10 Cc. of water, it will be converted into white mercuric oxalate (distinction from red mercuric oxide). On dissolving 0.1 Gm. of the Oxide in 10 Cc. of diluted nitric acid, the resulting solution should be clear, and should not afford more than a slight opalescence with silver nitrate T.S. (limit of chlorides). The solution of 0.5 Gm. of the Oxide in a mixture of 2 Cc. of hydrochloric acid and 25 Cc. of water, should not respond to the tests for foreign salts, metals, or arsenic, as described under *Hydrargyri Chloridum Mite*."

U. S. "A yellow powder yielding nothing to water, but being readily dissolved by hydrochloric acid, the solution affording the reactions characteristic of mercuric salts. Gently heated it assumes a red color. Heated to incipient redness it is resolved into oxygen and the vapor of mercury, leaving only an insignificant amount of fixed residue; the proportion of metallic mercury obtained being 92 to 92.5 per cent." *Br.* I. Comere explains in a paper in *Répert. de Pharm.*, 1881, 199, the various conditions and modifications in the process necessary to make the oxide vary in color. (*N. R.*, 1882, 149.)

Uses.—The attention which has been recently paid to the yellow oxide is owing to its peculiar applicability to the local treatment of diseases of the eye, in consequence of its amorphous character. B. Squire of England, was the first to notice publicly this use of the oxide (*P. J.*, 2d ser., vi. 512). At present the yellow oxide is very largely used by oculists throughout the world. The red oxide, however carefully it may be triturated, even though in a perfectly impalpable state, still shows under the microscope crystalline particles, which in contact with the conjunctiva cause more or less irritation; it can, therefore, be readily understood that, in the ordinary mode of preparing it for use as an ointment, it may sometimes be productive of serious annoyance. From this objection the yellow oxide is exempt.

Neither Pharmacopœia gives at present an official process for this oxide. For former processes, see below.¹

solving mercury in an excess of nitric acid), any convenient quantity; solution of sodium hydroxide, *U. S. P.*, a sufficient quantity. The solution of mercuric nitrate is diluted with an equal bulk of water, and added to the solution of sodium hydroxide; the latter should be in slight excess. The yellow precipitate is collected, washed well, and dried.

¹"Take of Mercury thirty-six troyounces; Nitric Acid twenty-four troyounces; Water two pints. Dissolve the Mercury, with the aid of a gentle heat, in the Acid and Water previously mixed, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel until red vapors cease to rise." *U. S.* 1870. "Take of Mercury, by weight, eight ounces [avoirdupois]; Nitric Acid four

The preparation is still frequently called by its older name, *red precipitate*. The name of *red mercuric oxide* is appropriate, as mercuric nitrate exists in it merely as an accidental impurity, and there is no occasion to distinguish the preparation from the oxide obtained by calcining mercury, the latter not being official, and perhaps never employed.

In the preparation of this mercurial, various circumstances influence the nature of the product, and must be attended to, if it is desired to procure the oxide with that fine bright orange-red color, and shining scaly appearance, usually considered desirable. Among these circumstances is the condition of the mercuric nitrate submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in some of the official processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep orange color. Care must be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. According to R. Dufass a mercuric oxide which combines the good properties of both red and yellow oxides, without any of their disadvantages, is obtained as follows: 125 Gm. of potassium carbonate and 500 Gm. of water are heated to boiling, and a solution of 100 Gm. of mercuric chloride in 1875 Gm. of water is slowly added under continued boiling. The resultant precipitate, after washing and drying, is obtained as an orange-yellow crystalline powder. (*Süddeut. Apoth. Ztg.*, 1902, 836.) Payssé, who paid great attention to the manufacture of red precipitate, recommended 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more will be useless. It is not necessary that the salt should

be removed from the vessel in which it is formed; it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A glass flask may be used with a large flat bottom, so that an extended surface may be exposed and all parts heated equally. The metal and acid having been introduced, the flask should be placed in a sand bath, and covered with sand up to the neck. The solution of the mercury should be favored by a gentle heat, which should afterwards be gradually increased till red vapors appear, then maintained as equably as possible until these vapors cease and at last slightly elevated until oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the flask, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the flask being still allowed to remain in the sand bath. These last precautions are said to be essential to the fine red color of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more uniformly maintained. The former direction of the Br. Ph., to rub a portion of mercury with the nitrate before decomposing it, renders the process more economical, as the nitric acid, which would otherwise be dissipated, is thus employed in oxidizing an additional quantity of the metal. As the process is ordinarily conducted in laboratories, the mercuric nitrate is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand, in the chamber of an oven or furnace, provided with a flue for the escape of the vapors. Each vessel may conveniently contain ten pounds of the nitrate. There is always loss in the operation thus conducted.¹ Egeling states that this oxide can be prepared by precipitation so that the resulting product cannot be distinguished from that made by ignition. Into a boiling solution of mercuric chloride (1 : 5) a boiling concentrated solution of potassium hydroxide is poured, until the dark brown color of the oxychloride is changed to a bright red, and the liquid reacts faintly alkaline; this is poured into 20 volumes of boiling water, and the precipitate collected, washed and drained. (*Ph. Ztg.*, 92, 517.)

Properties.—Red precipitate, well prepared, has a brilliant red color, with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Barker found 1000 parts to take up 0.62 of the oxide. Christison found 1 part of the oxide to be dissolved by about 7000 parts of boiling water, and the solution to give a black

fluidounces and a half [Imperial measure]; Water two fluidounces [Imp. meas.]. Dissolve half the Mercury in the Nitric Acid diluted with the Water, evaporate the solution to dryness, and with the dry salt thus obtained, triturate the remainder of the Mercury until the two are uniformly blended together. Heat the mixture in a porcelain dish, with repeated stirring, until acid vapors cease to be evolved." *Br.* 1885.

In this process the mercury is dissolved by the nitric acid, forming either mercuric nitrate, or a mixture of this with mercurous nitrate. The resulting mass when exposed to a strong heat is decomposed, giving out red nitrous fumes, and assuming successively a yellow, an orange, and a brilliant purple-red color, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the mercurous oxide, if any be present, is converted into mercuric oxide, while nitrogen dioxide gas escapes, and becomes nitrogen tetroxide on contact with the air. The mercuric oxide is left behind, but in general not quite free from the nitrate, which cannot be wholly decomposed by heat without endangering the decomposition of the oxide itself, and the volatilization of the metal.

¹ For a process for *Hydrargyrum precipitatum per se, precipitate per se, or calcined mercury*, all practically identical with red mercuric oxide, see U. S. D., 17th ed., 704.

precipitate with hydrogen sulphide. Tannic acid precipitates metallic mercury from an aqueous solution of the oxide, especially when heated. (Bullock, *Proc. A. Ph. A.*, 1858, p. 306.) It is insoluble in cold alcohol and ether. (*Ibid.*) Nitric and hydrochloric acids dissolve it without effervescence. "Heavy, orange-red, crystalline scales, or a crystalline powder, becoming more yellow the finer it is divided; odorless, and having a somewhat metallic taste; permanent in the air. Almost insoluble in water, insoluble in alcohol, but readily and completely soluble in diluted hydrochloric or nitric acid, forming colorless solutions. When heated to about 400° C. (752° F.), Red Mercuric Oxide becomes dark violet or almost black, but assumes its original color on cooling. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving no appreciable residue. If 0.5 Gm. be digested on a water-bath with a solution of 1 Gm. of oxalic acid in 10 Cc. of water, it will not change color within two hours (distinction from yellow mercuric oxide). If 1 Gm. of Red Mercuric Oxide be mixed with 5 Cc. of water, and 2 Cc. of sulphuric acid added, the mixture cooled, and 2 Cc. of ferrous sulphate T.S. be carefully poured upon it, no brown zone should be developed at the line of contact upon standing (absence of nitrate). On dissolving 0.1 Gm. of the Oxide in 10 Cc. of diluted nitric acid, the resulting solution should be clear, and should not produce more than a slight opalescence with silver nitrate T.S. (limit of chlorides). The solution of 0.5 Gm. of the Oxide in a mixture of 2 Cc. of hydrochloric acid and 25 Cc. of water, should not respond to the tests for foreign salts, metals, or arsenic, as described under *Hydrargyri Chloridum Mite.*" U. S. "Orange-red crystalline scales or powder answering to the tests given under '*Hydrargyri Oxidum Flavum.*' When gently heated it becomes dark violet, but resumes its orange-red color on cooling. When heated in a dry test-tube it should not evolve orange fumes (absence of nitrates)." Br. It is essentially mercuric oxide, consisting of one atom of the metal 198.5, and one of oxygen 15.88 = 214.38; but in its ordinary state it always contains a minute proportion of nitric acid, probably in the state of subnitrate. According to Brande, when rubbed and washed first with a solution of potassium hydroxide, and then with distilled water, and carefully dried, it may be regarded as nearly pure mercuric oxide. It is said to be sometimes adulterated with brickdust, red lead, etc., but these may be readily detected, as mercuric oxide is wholly dissipated if thrown upon red hot iron. The disengagement of red vapors when it is heated indicates the presence of mercuric nitrate.

Uses.—This preparation is too harsh and irregular in its operation for internal use, but is still employed externally as a stimulant and escharotic in the state either of powder or of ointment, although to a great extent supplanted

by the yellow oxide. The powder is sprinkled on the surface of *chancres*, and *indolent, flabby*, or *fungous ulcers*. The powder should be finely levigated.¹

MERCURY [Quicksilver]

(hÿ-drär'gy-rûm)

Hg = 198.50

"It should contain not less than 99.9 percent. of pure metallic Mercury, and should be kept in strong, well-stoppered bottles." U. S. "A metal obtained from native mercuric sulphide." Br.

Hydrargyrum Vivum, Mercurius Vivus, Argentum Vivum; Mercure Purifié, Fr. Cod.; Vif Argent, Fr.; Hydrargyrum, P. G.; Quecksilber, G.; Mercurio, It., Sp.

Mercury is found pure, forming an amalgam with silver, in the form of chloride (native calomel), but most abundantly as the sulphide or native cinnabar. Mines of this metal are found at Almaden in Spain, at Idria in Carniola, in the former duchy of Deux-Ponts, in Belluno, a province of Venetia, in Corsica, in the Philippine Islands and China, near Huan-cavelica in Peru, near Azogue in Colombia, at Durango in Mexico, at Yulgilbar, New South Wales, at New Almaden, New Idria, and other localities in Santa Clara County, California, about sixty-six miles from San Francisco, and in Brewster and other counties in Texas. The most ancient mine is that of Almaden in Spain, which was worked before the Christian era. This mine, and the mines of California, are the most productive at the present day, the Spanish mine yielding about three and a quarter millions of pounds, and the California mines about two-thirds of this amount annually. The ore in all the mines mentioned is cinnabar. The cinnabar from old Almaden is of a dull-red color in mass, of a dull brick-red color when in fine powder, and of the sp. gr. 3.6. That from New Almaden is of a bright-red color, slightly inclining to purple, not so hard as the Spanish ore, of a brilliant vermilion color in powder, and of the sp. gr. 4.4. The California cinnabar is richer in mercury, because purer, than the Spanish, the former yielding about 70 and the latter about 38 per cent. of mercury, according to the analysis of Adam Bealey. The California mine had been long known to the Indians, but its commercial value was first made known about 1843, by a Mexican, named Castillero, who became its first owner. At present it is in the hand of Americans. Ruschenberger has detected selenium in California cinnabar.

¹ *Hydrargyri Oxidum Nigrum*, U. S. 1850. *Black Mercurous Oxide.*—This preparation has been dropped from both Pharmacopœias, and is now very rarely used. For a full account of its preparation, uses, and properties, see U. S. D., 14th ed., 1256.

Extraction.—Mercury is obtained almost exclusively from the sulphide or native cinnabar. It is extracted by two principal processes. According to one process, the mineral is picked, pounded, and mixed with lime. The mixture is then introduced into cast iron retorts, which are placed in rows, one above the other, in an oblong furnace, and connected with earthenware receivers one-third full of water. Heat being applied, the lime combines with the sulphur, so as to form calcium sulphide and sulphate, while the mercury distils over, and is condensed in the receivers. The other process is practised at Almaden in Spain. Here a square furnace is employed, the floor of which is pierced with many holes, for the passage of the flame from the fireplace beneath. In the upper and lateral part of the furnace, holes are made, communicating with several rows of *aludels*, formed of adapters passing into one another, which terminate in a small chamber that serves both as condenser and receiver. The mineral, having been picked by hand and pulverized, is kneaded with clay, and formed into small masses, which are placed on the floor of the furnace. Heat being applied, the sulphur burns, and the volatilized mercury passes through the *aludels* to be condensed in the chamber.

Mercury, as found in commerce, is contained in cylindrical wrought iron bottles, called flasks, each containing $76\frac{1}{2}$ pounds.¹ Since the regular working of the California mine of New Almaden, the importation of the metal from Spain and Austria has gradually diminished, and at present the domestic production is sufficient not only to supply the home consumption, but to give an excess for exportation. In the year 1862 the different mines of California were said to be yielding mercury at the rate of four millions of pounds per annum (*A. J. P.*, Sept. 1862, 410), which had increased in 1877 to over six million pounds, but then fell off again. The production for 1903 was 35,620 flasks, of which California produced 30,591 and Texas 5029; for 1904, 34,570 flasks, of which California produced 29,234 and Texas 5336. The world's production at present is about 7,000,000 lbs. The exports are made principally to China, Mexico, Chili, and Peru. The chief uses of the metal are in mining silver and gold, in preparing vermilion, in making thermometers and barometers, in silvering looking glasses, and in forming various pharmaceutical compounds.

Properties.—Mercury is "a shining, silver-white metal, without odor or taste. It is liquid at ordinary temperatures and easily divisible into spherical globules; but when cooled to -39.38° C. (-38.88° F.), it forms a ductile, malleable mass. Specific gravity: 13.535 at 25° C. (77° F.). Insoluble in the ordinary solvents, also in concentrated hydrochloric acid, and, at ordinary temperatures, in sulphuric

acid; but it dissolves in the latter when boiled with it, and is readily and completely soluble in nitric acid. At ordinary temperatures it volatilizes very slowly, more rapidly as the temperature increases, and at 357.25° C. (675.05° F.), it boils and is completely volatilized, yielding a colorless, very poisonous vapor, and no appreciable residue. When globules of Mercury are dropped upon white paper, they should roll about freely, retaining their globular form, and leaving no streaks or traces. It should be perfectly dry and present a bright surface even after agitation in contact with air. On boiling 5 Gm. of Mercury with 5 Cc. of water and 4.5 Gm. of sodium thiosulphate, in a test-tube for about one minute, the Mercury should not lose its lustre, and should not acquire more than a slightly yellowish shade (absence of more than *slight traces of foreign metals*)."
U. S. When perfectly pure it undergoes no alteration by the action of air or water, but in its ordinary state suffers a slight tarnish. When heated to near the boiling point, it gradually combines with oxygen, and is converted into mercuric oxide; but at the temperature of ebullition it parts with the oxygen with which it had combined, and is reduced again to the metallic state. It boils at 357.25° C. (675.05° F.), yielding a colorless vapor, and congeals at -39.4° C. (-39° F.), forming a malleable solid of tin-white color. It is a good conductor of heat, and its specific heat is small. It is not attacked by hydrochloric acid, nor by cold sulphuric acid; but boiling sulphuric acid or cold nitric acid dissolves it, producing mercurous sulphate and mercurous nitrate, respectively, with the extrication, in the former case, of sulphurous acid; in the latter, of nitrogen dioxide, becoming hyponitric acid fumes. Its combinations are numerous, and several of them constitute important medicines. It forms two series of compounds, the *mercurous* compounds containing the atom Hg^I , and the *mercuric* compounds containing the atom Hg^{II} .

Mercury, as it occurs in commerce, is in general sufficiently pure for pharmaceutical purposes. Occasionally it contains foreign metals, as lead, tin, zinc, and bismuth. Brande informs us that in examining large quantities of this metal in the London market he found it in only one instance intentionally adulterated. When impure, the metal has a dull appearance, leaves a trace on white paper, is deficient in due fluidity and mobility, as shown by its not forming perfect globules, is not totally dissipated by heat, and when shaken in a glass bottle coats its sides with a pellicle, or, if very impure, deposits a black powder. If agitated with strong sulphuric acid, the adulterating metals become oxidized and dissolved, and thus the mercury may to a limited extent be purified. Lead is detected by shaking the suspected metal with equal parts of acetic acid and water, and then testing the acid by sodium sulphate or potassium iodide. The former will

¹ Since June 1st, 1904, the flasks have contained uniformly 75 lbs.

produce a white, the latter a yellow, precipitate, if lead be present. Bismuth is discovered by dropping a nitric solution of the mercury, prepared without heat, into distilled water, when bismuth subnitrate will be precipitated. The complete solubility of the metal in nitric acid shows that tin is not present, and, if hydrogen sulphide does not act upon hydrochloric acid previously boiled upon the metal, the absence of contaminating metals is shown. Mercury may be purified by digesting it with a small portion of weak nitric acid, or with a solution of mercuric chloride, whereby all the ordinary contaminating metals will be removed. The purification by nitric acid is, according to L. Meyer (*Zeit. An. Chem.*, ii. 241), best effected as follows: The metal is allowed to flow in a very thin stream from a small opening in a glass funnel into a wide glass tube 1.25 M. high and 5 cm. in diameter, which contains a dilute mixture of water and nitric acid. A narrow tube is fastened to the bottom of this, curved upward so as to discharge the mercury at a height of 10 cm. above the lower end of the wide tube; from this the pure metal flows; it has then only to be washed with water and dried. The above operation may have to be repeated several times, and the metal if pure must leave no residue when dissolved in pure nitric acid, evaporated to dryness, and ignited. To separate mechanical impurities, moisture, or small quantities of oxide, mercury may be filtered by collecting it in a sound piece of chamois leather and gathering the corners together, forcibly squeezing the particles through the pores of the leather. Mercury, however, is usually purified by distillation.¹ Being much more volatile than the contaminating metals, it rises first in distillation, while they are left behind. But it is necessary to avoid pushing the distillation too far, for in that event some of the foreign metals are apt to be carried over. The British Council, on account of this danger, directed only five-sixths of the mercury to be distilled. The distilled product is boiled for a few minutes with diluted hydrochloric acid, which, while it does not attack the mercury, dissolves any contaminating metals which may have passed over. The distillation is directed to be performed from a glass retort or iron bottle; but it is more conveniently conducted from the latter, over a common fire, into water contained in a receiver. In small operations a wash hand basin will answer for a receiver.

¹ The British Pharmacopœia of 1864 gave the following process for the purification of mercury, using for this purpose an impure form of the metal, under the name of *Commercial Mercury* or *Quicksilver*:

"Take of Mercury of Commerce three pounds [avoirdupois]; Hydrochloric Acid three fluidrachms; Distilled Water a sufficiency. Place the Commercial Mercury in a glass retort or iron bottle, and applying heat cause two pounds and a half of the metal to distil over into a flask employed as a receiver. Boil on this for five minutes the Hydrochloric Acid diluted with nine fluidrachms of Distilled Water, and having, by repeated affusions of Distilled Water, and decantations, removed every trace of acid, let the mercury be transferred to a porcelain capsule, and dried first by filtering paper, and finally on a water-bath." *Br.* 1864.

Millon has ascertained the curious fact that the presence of so small a quantity as one ten-thousandth of lead or zinc in mercury raises its boiling point. Violette has made known a method of distilling mercury, or amalgamated silver, which presents many advantages. It consists in subjecting the metal, in iron vessels, to a current of high pressure steam, which serves the double purpose of imparting the necessary heat, and carrying over the mercurial vapor by a mechanical agency. (*Philos. Mag.*, Dec. 1850.) As it is difficult and troublesome to purify mercury by distillation, it is better to purchase pure samples of the metal, which may always be found in the market.¹

Mercury is detected with great delicacy by Smithson's process, which consists in the use of a plate of tin, lined with one of gold, in the form of a spiral. When immersed in a mercurial solution, this galvanic combination causes the precipitation of the mercury on the gold, which consequently contracts a white stain. In order to be sure that the stain is caused by mercury, the metal must be volatilized in a small tube, so as to obtain a characteristic globule. Danger and Flandin have improved on Smithson's process. (See *Chem. Gaz.*, No. 61, p. 191.) A minute portion of any of the preparations of mercury, either in the solid state or in concentrated solution, being placed on a bright plate of copper, and a drop of a strong solution of potassium iodide added, a silvery characteristic stain will immediately appear on the copper.

Uses.—Mercury in its uncombined state is inert, but in combination acts as a peculiar and universal stimulant. When exhibited in minute division, as it exists in several preparations, it produces its peculiar effects, but this does not prove that the uncombined metal is active, but only that the condition of minute division is favorable to chemical combination, and consequently to its solution in the stomach. Its compounds exhibit certain general medicinal properties and effects which belong to the whole as a class, while each individual preparation is characterized by some peculiarity in its operation. In this place we shall consider the physiological action of mercury, and the principles by which its administration should be regulated; its effects as modified in its different combinations will be noticed under the head of the several preparations. Of the *modus operandi* of mercury we know nothing, except that it possesses a peculiar alternative power over the vital functions. This alternative power

¹ **Measuring Definite Quantities of Mercury.**—H. Kral calls attention to a simple method for measuring mercury in operations in which approximately identical quantities of the metal are required. It consists of using a goose quill, into which the necessary quantity of mercury has been weighed. A small hole is then cut immediately above the surface of mercury, and the apparatus is ready for use. By simply immersing it into the bottle containing the mercury, it is filled through the opening, and uniform quantities, sufficiently accurate for practical purposes, are thus easily measured.—*Ph. Centralt.*, 1895, 422, 423.

is sometimes exerted without being attended with any other vital phenomenon than the removal of disease, while at other times it is accompanied with certain obvious effects, such as a quickened circulation, a frequent jerking pulse, and increased activity of all the secretory functions, particularly those of the salivary glands and the liver. When mercury acts slowly as an alterative, there is not the least apparent disturbance of the circulation. When it operates decidedly and obviously, it is very prone to cause an immoderate flow of saliva and produce the condition denominated ptyalism or salivation. Mercury has been detected in most of the solids and fluids of the body, including the blood. When in the blood it cannot be detected by the ordinary tests, on account of its intimate union with the organic matter of that liquid. To discover it, the blood must be subjected to destructive distillation. The liver is the organ which retains mercury the longest. It has been detected in that viscus though absent in the lungs, heart, bile, and spinal marrow.¹ Mercury has been used in almost every disease, but too often with evil results. In functional derangement of the digestive organs, mercurials in minute doses often exert a salutary operation, subverting the morbid action, and that, too, by their slow, alterative effects, without affecting the mouth. In these cases, no decided disturbance of the vital function takes place, but the alvine discharges, if clay-colored, are generally restored to their natural hue; whether the liver be torpid and obstructed as in *jaundice*, or pouring out a redundancy of morbid bile as in *melæna*, the judicious use of mercury seems equally efficacious in unloading the viscous, or restoring its secretion to a healthy state. In chronic inflammation of the mucous and serous membranes, the alterative effects of mercury are sometimes attended with much benefit. In many of these cases effusion has taken place, and under these circumstances the mercury often proves useful as well by promoting absorption as by removing the chronic inflammation on which the effusion depends. Hence it is often given with advantage in chronic forms of *meningitis*, *bronchitis*, *pleuritis*, *pneumonitis*, *dysentery*, *rheumatism*, etc., and in *hydrocephalus*, *hydrothorax*, *ascites*, and *general dropsy*. Mercury may also be advantageously resorted to in certain states of febrile disease. In some forms of *remittent* and *typhoid fever*, a particular stage is marked by a parched tongue, torpor of the bowels, scanty urine, and dryness of the surface. Here the very cautious employment of mercury is sometimes serviceable. It acts in such cases by increasing the secretions.

In syphilitic affections, mercury, until of late years, was held to be indispensable. Of its mode of action in these affections we know nothing. Without entering into the question

of the necessity of mercury in venereal complaints, we are free to admit that the discussion which has grown out of it has shown that this remedy has frequently been unnecessarily resorted to in *syphilis*. For inducing the specific effects of mercury on the constitution, blue pill or calomel is generally resorted to. In order to procure what has been called the slow alterative effects of the metal, from half a grain to a grain (0.032 to 0.065 Gm.) of blue pill may be given in the twenty-four hours, or from a sixth to a fourth of a grain (0.01 to 0.016 Gm.) of calomel; or, if a gentle ptyalism be desired, two or three grains (0.13 or 0.20 Gm.) of the former, or a grain of the latter (0.065 Gm.) may be given two or three times a day. Where the bowels are peculiarly irritable, it is often necessary to introduce the metal by means of friction with mercurial ointment. Where a speedy effect is desired, the metal may be advantageously given hypodermically.

The first observable effects of mercury in inducing ptyalism are a coppery taste in the mouth, a slight soreness of the gums, and an unpleasant sensation in the sockets of the teeth when the jaws are firmly closed. Shortly afterwards the gums begin to swell, a line of whitish matter is seen along their edges, and the breath is infected with a peculiar and very disagreeable odor, called the mercurial fetor. The saliva at the same time begins to flow, and, if the affection proceed, the gums, tongue, throat, and face become much swollen; ulcerations attack the lining membrane of the mouth and fauces; the jaws become excessively painful; the tongue is coated with a thick whitish fur, and the saliva flows in streams from the mouth. It occasionally happens that the affection of the mouth proceeds to a dangerous extent, inducing extensive ulceration, gangrene, and even hemorrhage. The best remedies are astringent and detergent gargles, used weak at first, as the parts are extremely tender. In cases attended with swelling and protrusion of the tongue, the wash is best applied by injection by means of a large syringe. We have found lead water among the best applications in these cases, and diluted solutions of chlorinated soda or of chlorinated lime, while they correct the fetor, will be found to exert a curative influence on the ulcerated surfaces. A wash of silver nitrate, made by dissolving eight grains (0.5 Gm.) in a fluid-ounce (30 Cc.) of water, has also been used with benefit. While the system is under the action of mercury the blood is more watery than in health, less charged with albumin, fibrin, and red globules.

In the foregoing observations we have described the ordinary effects of mercury, but occasionally, in peculiar constitutions, its operation is quite different, being productive of a dangerous disturbance of the vital functions. Pearson gave a detailed account of this occasional peculiarity in the operation of mercury, in his work on venereal diseases. The symp-

¹ For a method of detecting mercury in the urine, see P. J., Aug. 1873, 145.

toms which characterize it are a small and frequent pulse, anxiety about the præcordia, pale and contracted countenance, great nervous agitation, and alarming debility. Their appearance is the signal for discontinuing the mercury, as a further perseverance with it might be attended with fatal consequences. Mercury also produces a peculiar eruption of the skin, which is described by writers under the various names of *hydrargyria*, *eczema mercuriale*, and *lepra mercurialis*. Those who work in mercury, and are, therefore, exposed to its vapor, such as looking-glass silverers, and quicksilver miners, are injured seriously in their health, and not unfrequently affected with shaking palsy, attended with vertigo and other cerebral disorders. The miners are often salivated.

Many plants, exposed to the influence of the vapor spontaneously rising from mercury in confined air, perish in a few days, while if sulphur be placed by the side of the metal no effect of the kind is experienced. (Boussingault, *J. P. C.*, Sept. 1867, p. 176.) A probable inference from this fact is that workmen necessarily exposed to the vapor of mercury might be protected by the presence of sulphur in sufficient quantity.

Mercury is sometimes given in the metallic state, in the quantity of a pound or two, in *obstruction of the bowels*, to act by its weight; but the practice is of doubtful advantage.

AMMONIATED MERCURY [White Precipitate]

(hŷ-drär'gy-rūm am-mō-nī-ā'tūm)

$\text{HgNH}_2\text{Cl} = 249.61$

"It should contain not less than 78 percent. nor more than 80 percent. of metallic mercury." *U. S.*

Hydrargyri Præcipitatum Album; Hydrargyrum Amidato-bichloratum (ammoniato-muriaticum), Mercurius Præcipitatus Albus; Hydrargyri Ammonio-Chloridum; Ammonio-chloride of Mercury, Mercuric Ammonium Chloride; Mercuric amidio-chloride; Chloramidure de Mercure, Oxychlorure Ammoniacal de Mercure, Lait Mercuriel, Mercure Præcipité Blanc, *Fr.*; Hydrargyrum præcipitatum album, *P. G.*; Weisser Quecksilberpräcipitat, Quecksilber-Chloridamid, *G.*; Cloramiduro di mercurio, *It.*

* "Corrosive Mercuric Chloride, in powder, one hundred grammes [or 3 ounces av., 231 grains]; Ammonia Water, Distilled Water, each, a sufficient quantity. Dissolve the Corrosive Mercuric Chloride in two thousand cubic

centimeters [or 67 fluidounces, 5 fluidrachms] of warm Distilled Water, filter the solution, and allow it to cool. Pour the filtered liquid gradually, and with constant stirring, into one hundred and fifty cubic centimeters [or 5 fluidounces, 35 minims] of Ammonia Water, taking care that the latter shall remain in slight excess. Collect the precipitate on a filter, and, when the liquid has drained from it as much as possible, wash it with a mixture of four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Distilled Water and twenty cubic centimeters [325 minims] of Ammonia Water. Finally, dry the precipitate between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.), and keep it in well-stoppered bottles, protected from light." *U. S.*

"Mercuric Chloride, 3 ounces (Imperial) or 60 grammes; Solution of Ammonia, 4 fl. ounces (Imp. meas.) or 80 cubic centimetres; Distilled Water, a sufficient quantity. Dissolve the Mercuric Chloride in three pints (Imp. meas.) or twelve hundred cubic centimetres of the Distilled Water with the aid of heat; pour the liquid into the Solution of Ammonia diluted with one pint (Imp. meas.) or four hundred cubic centimetres of Distilled Water, constantly stirring; collect the precipitate on a filter; wash it well with cold Distilled Water until the liquid which passes through is free from chloride; dry the product at a temperature not exceeding 212° F. (100° C.)." *Br.*

The Pharmacopœias now agree in obtaining white precipitate by precipitating a solution of mercuric chloride by ammonia. When ammonia, in slight excess, is added to a cold solution of mercuric chloride, ammonium chloride is formed in solution, and the white precipitate of the Pharmacopœias thrown down. The precipitate is washed with a diluted solution of ammonia, according to the *U. S.* formula, according to the British, with greater precision, until the washings cease to give evidence of the presence of a chloride by producing a precipitate with silver nitrate acidulated with nitric acid. Power states that washing to this extent results in a considerable degree of decomposition. The substance washed away is ammonium chloride with the excess of ammonia employed; hence the washings, agreeably to the directions of the British formula, are tested with an acid solution of silver nitrate. The white precipitate forms according to the following reaction:

In other words, one molecule of the mercuric chloride reacts with two of the ammonia, and yields one molecule of ammonium chloride and one of mercur-ammonium chloride, or white precipitate. A method of making white precipitate, said to be employed by large manufacturers, substitutes ammonium chloride and sodium carbonate for ammonia. As the product contains less mercury than the official preparation, and is in commerce, it is important to be able to distinguish the two. According

to Redwood, this can be done by heating, the official preparation volatilizing without fusing, the unauthorized fusing before volatilizing. Attfield has, however, shown that fusibility does not necessarily indicate that the specimen contains 65 per cent. of mercury, nor infusibility demonstrate that it contains the official proportion of 79½ per cent. The commercial variety differs somewhat from the present official preparation in composition, its formula being Na HgCl_2 (or *mercur-diammonium chloride*). (See paper by F. X. Moerk, A. J. P., 1888.)

Properties.—"White, pulverulent pieces, or a white, amorphous powder, without odor, and having an earthy, afterwards styptic and metallic taste; permanent in the air. Insoluble in water or in alcohol. By prolonged washing with water it is gradually decomposed, assuming a yellow color, and becoming converted into a basic salt. Readily soluble in warm hydrochloric, nitric, or acetic acid, and in a cold solution of ammonium carbonate. Also completely soluble in a cold solution of sodium thiosulphate, with the evolution of ammonia; when this solution is heated for a short time, red mercuric sulphide is separated, which, on protracted boiling, turns black. At a temperature below a red heat Ammoniated Mercury is decomposed without fusion, and at a red heat it is wholly volatilized. When heated with potassium hydroxide T.S., the salt turns yellow, and evolves vapor of ammonia. The solution of the salt in diluted nitric acid gives with potassium iodide T.S. a red precipitate and with silver nitrate T.S. a white precipitate. The salt should be soluble in hydrochloric acid without effervescence (absence of carbonate), and without leaving a residue (absence of mercurous salt). The solution of 0.5 Gm. of Ammoniated Mercury in 2 Cc. of hydrochloric acid diluted with water to 25 Cc. should not respond to the tests for foreign salts, metals, and arsenic, as described under *Hydrargyri Chloridum Mite*." U. S. "A white powder on which water has but little action, and alcohol (90 per cent.) or ether no action. Digested with solution of potassium hydroxide, it evolves ammonia, acquiring a pale yellow color, and the liquid, filtered and acidulated with nitric acid, gives a white precipitate with solution of silver nitrate. Boiled with solution of stannous chloride it becomes gray, and yields globules of metallic mercury. It volatilizes at a temperature under redness, without fusing, leaving only an insignificant amount of fixed residue. When heated with excess of lime it should yield 78 to 79 per cent. of metallic mercury." Br.

Adulteration with white lead, chalk, or calcium sulphate may be detected by exposing a sample to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charred residue will be obtained on the application of heat. Lead or starch may be found by digesting it with acetic acid, and testing the acetic solution with the compound

solution of iodine, which will give a yellow precipitate if lead and a blue one if starch be present. The absence of mercurous oxide is shown by its not being blackened when rubbed with lime water.

Uses.—Ammoniated mercury is used only as an external application. Mercur-diammonium chloride is said to produce an ointment more translucent and less white than the genuine, and more apt to become yellow on being kept. (J. Borland, P. J., Dec. 1867, p. 262.)

Ammoniated mercury has been swallowed by mistake. It is highly poisonous, producing gastric pain, nausea, and purging. For recovery after taking half a drachm, see L. L., July 4, 1857. The remedies employed were an emetic of zinc sulphate and milk.

HYDRARGYRUM CUM CRETA.

U. S., Br.

MERCURY WITH CHALK

(hý-drär'gy-rüm cūm crē'tā)

Gray Powder; Æthiops Cretaceus; Mercure avec la Craie, Poudre de Mercure crayeux, Fr.; Quecksilber mit Kreide, G.

* "Mercury, thirty-eight grammes [or 1 ounce av., 150 grains]; Clarified Honey, ten grammes [or 154 grains]; Prepared Chalk, fifty-seven grammes [or 2 ounces av., 5 grains]; Water, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Weigh the Mercury and Clarified Honey successively into a strong bottle of the capacity of one hundred cubic centimeters [or 3 fluid-ounces, 183 minims], and add two cubic centimeters [or 32 minims] of Water. Cork the bottle, and shake it for about half an hour at a time, until the aggregate time of shaking reaches ten hours, or until the globules of Mercury are no longer visible under a lens magnifying four diameters. The shaking may be more conveniently performed by mechanical means. Rub the Prepared Chalk with Water, in a mortar, to a thick, creamy paste, and, having added the contents of the bottle, washing the last portions in with a little Water, triturate the whole to a uniform mixture. Finally, dry the mixture, first between ample layers of bibulous paper, and afterwards in a dish at the ordinary temperature, until it weighs one hundred grammes [or 3 ounces av., 231 grains]. Then reduce it to a uniform powder, without trituration, and keep it in well-stoppered bottles, protected from light." U. S.

"Mercury, 1 ounce (Imperial) or 20 grammes; Prepared Chalk, 2 ounces (Imp.) or 40 grammes. Rub the Mercury and Prepared Chalk in a porcelain mortar until the metallic globules cease to be visible to the naked eye, and the mixture acquires a uniform grey color." Br.

The method of making this mercurial directed by the U. S. P. 1880 was so faulty as to be inoperative, and it has been abandoned; the U. S. P. 1890 process for making mercury with chalk was based upon Squibb's method of succussion, which was retained and is described at length farther on. When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic lustre and becomes a blackish or dark-gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens, and the mercury is said to be extinguished. It was formerly thought that the metal was oxidized in the process. At present the change is generally ascribed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury in which the metal is extinguished by trituration, a very small portion is converted into mercurous oxide, while by far the greater part remains in the metallic state.

Mercury with chalk is officially described as "a light gray, rather damp powder, free from grittiness, without odor, and having a slightly sweetish taste. If a portion of the powder be digested with warm acetic acid, the chalk is dissolved with effervescence, leaving a residue of finely divided mercury. The filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of mercurous oxide). If another portion of the powder be digested with warm, diluted hydrochloric acid, the filtrate should not be affected by hydrogen sulphide T.S., or by stannous chloride T.S. (absence of mercuric oxide)." U. S. "A powder of a light grey color; free from grittiness; insoluble in water; partly dissolved by diluted hydrochloric acid, leaving the mercury in a finely divided state. The solution formed with hydrochloric acid does not yield any white or grey precipitate on the addition of solution of stannous chloride (absence of mercuric compounds)." Br. Robert B. Matter suggests an improved process for its preparation whereby labor and time are saved; it is as follows. Mix twelve parts of finely powdered gum arabic with twelve parts of prepared chalk, triturate with sufficient water to form a rather thin paste, add thirty-eight parts of mercury, and continue the trituration until the globules of mercury have disappeared. Now add thirty-eight parts of finely powdered prepared chalk and sufficient water to form a thin paste, triturate, and when all the globules of mercury have disappeared, place the mortar in a hot water bath. The mixture distributed around the sides of the mortar will dry rapidly, when it can be easily scraped out, powdered

in a clean mortar, passed through bolting cloth, or a fine sieve, and finally rubbed lightly in a clean dry mortar; 8 ounces may be made by this process in an hour. (*A. J. P.*, 1886, 119.)

Mercury with chalk is a smooth, grayish powder, insoluble in water. Globules of mercury can generally be seen in it by the aid of a microscope, as the metal can scarcely be completely extinguished with chalk alone by any length of trituration. Jacob Bell found that by powerfully pressing it a considerable quantity of metal was separated in the form of globules. Phillips states that the extinguishment of the mercury is greatly accelerated by the addition of a little water. Stewart of Baltimore proposed the following process, by which he stated that the preparation might be completed in a short time, so that no globules should be visible with a powerful lens. Three ounces of mercury and six ounces of rosin are to be rubbed together for three hours; five ounces of chalk are to be added, and the trituration continued for an hour; the mixture is then to be heated with alcohol so as to dissolve the rosin; and the remaining powder is to be dried on bibulous paper and well rubbed in a mortar. (*A. J. P.*, xv. 162.) But Procter showed that the preparation thus made contains mercuric oxide, and is, therefore, injuriously harsh in its operation. (*Ibid.*, xxii. 113.) It is said that the precipitated black oxide is sometimes added with a view to save time in the trituration; but this must be considered as an adulteration, until it can be shown that the same oxide exists in the same proportion in the preparation made according to the official directions. Ed. Jenner Coxé of New Orleans, found that the extinguishment of the mercury may be effected "much more speedily than in the ordinary manner, by putting the ingredients into a quart bottle, to be well corked, and kept in constant agitation until the object is attained. A portion of chalk may be thus shaken with the metal until no globules can be seen, and the process completed by trituration with the remainder of the chalk in a mortar. This mode of proceeding was suggested to Coxé by W. Hewson of Augusta, Ga. (*Ibid.*, xxii. 317.) Squibb, having ascertained that the preparation cannot be satisfactorily made in this way on a large scale (*Proc. A. Ph. A.*, 1858, p. 424), invented a machine for accomplishing the same object, by which the requisite motion is imparted to the materials contained in two large bottles, and which is said to answer the purpose well. By means of this apparatus, E. R. Squibb prepared mercury with chalk on a large scale, mixing the materials in the official proportions, but aiding the extinguishment of the metal by mixing with it about one-seventh of its weight of honey, and adding this to the chalk made into a paste with water, and afterwards drying. (*Ibid.*, 1859, p. 359.) It has been shown that the preparation thus made resists oxidation most effectually, owing probably to the presence

of saccharine matter. (J. P. Remington, *A. J. P.*, Jan. 1869.) W. E. Bibby (*A. J. P.*, 1876, p. 269) recommends the rubbing of 3 troyounces of mercury, 4 troyounces of prepared chalk, and 1 troyounce of sugar of milk together in a mortar into an impalpable powder and passing the powder through a fine sieve. As found in commerce, mercury with chalk, instead of being the mild preparation intended, sometimes acts very harshly, causing vomiting, gastric pains, etc. This has been ascribed to the presence of antimony or arsenic, which, however, must be rare; the ordinary cause of the harshness is no doubt mercuric oxide, produced in minute proportion either during the trituration, or by the spontaneous change which occurs with time, mercurous oxide becoming mercuric oxide by the influence of light. The only sure method to guard against such results is to test the preparation carefully before dispensing it. (See *A. J. P.*, 1878, p. 325.) If the mercury contained in it be volatilized by heat, and the remaining chalk be dissolved by diluted acetic acid, the solution should not be colored by hydrogen sulphide. The presence of any probable metallic impurity may be detected in this way. To detect mercuric oxide, a portion of the powder may be treated with diluted hydrochloric acid with a moderate heat, and the solution tested by stannous chloride, which, if there be any mercuric oxide present, will cause a precipitation of metallic mercury as a black powder.

Uses.—Mercury with chalk is a very mild mercurial, similar in its properties to the blue mass, but much weaker. It is sometimes used as an alternative, particularly in the complaints of children attended with deficient biliary secretion, indicated by white or clay-colored stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in *diarrhœa*. Eight grains of the U. S. preparation contain about three grains of mercury. It should not be given in pill with substances which become hard on keeping, as the contraction of the mass presses together the particles of mercury, which in time appear in globules in the interior of the pill.

Dose, one to thirty grains (0.065 to 2 Gm.).

HYDRASTINA. U. S.

HYDRASTINE

(hỹ-drās-tĩ'ng)

$C_{21}H_{21}NO_8 = 380.32$

"An alkaloid obtained from Hydrastis. It should be kept in well-stoppered bottles." U. S.

Hydrastine, *Fr. Cod.*; Hydrastin, *G.*

Hydrastine may be obtained by exhausting the powdered root as far as possible with water by percolation, adding hydrochloric acid to the infusion so as to precipitate the berberine in the form of hydrochloride, and treat-

ing the mother liquor with solution of ammonia in slight excess. The hydrastine is precipitated, in an impure state, and may be purified by repeated solution in boiling alcohol, which deposits it in crystals on cooling. A little animal charcoal may be used towards the close of the process, in order to deprive the crystals completely of color. To Mahla of Chicago, and Perrins of London, is due the credit of having investigated this alkaloid.

Properties.—"White to creamy white, glistening prisms, sometimes of large size, possessing a bitter taste, and permanent in the air. It contains no water of crystallization. Almost insoluble in water at 25° C. (77° F.); soluble in 135 parts of alcohol, 124 parts of ether, and in 2 parts of chloroform at 25° C. (77° F.); soluble in 4000 parts of water at 80° C. (176° F.), and in 17 parts of alcohol at 60° C. (140° F.); easily soluble in benzene. Hydrastine melts at 131° C. (267.8° F.). It shows an alkaline reaction to moistened litmus paper, and is levogyrate. Sulphuric acid produces a yellow color when added to Hydrastine, and on heating, a purple color is developed. Sulphuric acid containing a trace of molybdic acid gives a green color, changing to olive-green and then to brown; nitric acid yields a reddish-yellow color; sulphuric acid containing a trace of selenous acid gives a yellowish-red color, changing to brown. Sulphuric acid containing a trace of potassium dichromate produces a red color, changing to brown. If a crystal of Hydrastine be dissolved in diluted sulphuric acid and a solution of potassium permanganate (1 in 10) be added, a blue fluorescence will be developed (distinction from *hydrastinine*)." U. S.

Uses.—Hydrastine is an active alkaloid, which is slowly absorbed and probably eliminated by the kidneys and lower bowel unchanged. When given to the lower animals it primarily stimulates the spinal motor cord, causing tetanic convulsions, with heightened reflexes, followed, if the dose has been large enough, by loss of reflex activity, and motor paralysis, which are probably in part due to depression of the motor centres, and are certainly, at least in part, the outcome of depression of the motor nerves and also of the muscles themselves. Death may occur in a convulsion from cramp-asphyxia, or later from simultaneous paralysis of the respiratory centre and of the peripheral apparatus. The arterial pressure is first elevated and secondarily depressed; the first rise of pressure is probably due to the stimulation of the heart muscle, increasing the output of force, and of both the vasomotor centres and the muscle fibres in the arteriole coats, causing contraction of the blood vessels; the fall of pressure is the result of a direct paralytic action exerted upon the muscle fibres in the heart and in the arterioles. Hydrastine notably increases intestinal peristalsis, and probably uterine contractions. It would seem to be a universal muscle poison, which

acts upon both striated and non-striated muscle fibres in heart, arterioles, intestines, uterus, and generally throughout the body, its first stimulant action being followed by marked depression. Hydrastine has been shown by Feller and Slavatski to have a distinct eebolic action, and premature labor is asserted to have been caused by its hypodermic administration. In practical medicine it is chiefly employed for the arrest of uterine hemorrhage, and in ordinary *menorrhagia*. When a prompt action is desired, a soluble salt like the hydrochloride should be administered hypodermically.

Locally, commercial hydrastin (a mixture of the alkaloids of hydrastis) is a valuable remedy in the treatment of *gonorrhœa*, *chronic gastric and intestinal catarrhs*, *otorrhœa*, *vaginitis*, *rinitis*, and other forms of catarrhal inflammation of the mucous membrane. For such purposes the impure mixture is probably superior to the pure alkaloid. From five to ten grains of commercial hydrastin or from fifteen to thirty minims of the fluidextract of hydrastis may be used in an ounce of diluent.

Dose, of pure hydrastine, one-sixth to one-half grain (0.01 to 0.032 Gm.).

HYDRASTININÆ HYDROCHLORIDUM. U. S.

HYDRASTININE HYDROCHLORIDE [Hydrastininæ Hydrochloras, Pharm. 1890, Hydrastinine Hydrochlorate]

(hŷ-drās-tj-nī'næ hŷ-drq-phlŷ'rj-dūm)

$C_{11}H_{11}NO_2 \cdot HCl = 223.88$

"The hydrochloride [$HCl \cdot C_{11}H_{11}NO_2$] of an artificial alkaloid derived from hydrastine. It should be kept in well-stoppered bottles." U. S.

Hydrastininum hydrochloridum, P. G.; Hydrastininhydrochlorid, Salzsäures Hydrastinin, G.

Preparation.—Hydrastinine is an artificial alkaloid, produced by acting on hydrastine, the alkaloid from hydrastis, with oxidizing agents. When manganese dioxide and sulphuric acid are used together, or when platinum chloride is employed, hydrastinine and opianic acid are the products.¹ (See *Hydrastis*.)

Properties.—Hydrastinine hydrochloride is officially described as in "light yellowish needles, or a yellowish-white, crystalline powder; odorless, and having a bitter taste. Very

soluble in cold and hot water, and in alcohol; soluble in 286 parts of chloroform and 1300 parts of ether at 25° C. (77° F.). Hydrastinine Hydrochloride melts at 212° C. (413.6° F.). Its aqueous solution, especially when highly diluted, shows a blue fluorescence, and is neutral to litmus paper. On ignition the salt should be completely consumed. In an aqueous solution of the salt (1 in 20), bromine T.S. produces a yellow precipitate, which should be perfectly soluble in ammonia water, forming an almost colorless solution. In an aqueous solution of the salt, potassium dichromate T.S. produces a precipitate which redissolves if gently heated, but on cooling the solution, it separates in glistening needles. If ammonia water be added to an aqueous solution of Hydrastinine Hydrochloride (1 in 20), no turbidity should be produced. On slowly adding to a solution of 0.2 Gm. of the salt in 3 Cc. of water 4 to 5 drops of solution of sodium hydroxide (1 in 7), each drop will cause a milky turbidity, which disappears again on shaking. From this solution, after standing for some time, pure white hydrastinine should separate, and the supernatant fluid should be almost colorless. With a crystal of the salt, sulphuric acid or nitric acid produces a deep yellow color; sulphuric acid with a trace of nitric acid, a reddish-brown color; sulphuric acid with a crystal of ammonium vanadate, a light brown color changing to dark brown." U. S.

Uses.—Hydrastinine is, when given in large enough amount, a powerful depressant to the whole motor tract, affecting the psycho-motor centres of the cerebral cortex, the motor nerve, and the muscle itself. In the present state of our knowledge it is uncertain whether the depression is or is not preceded by a brief period of excitation, but it is almost certain that there is a primary stimulation of the muscles. The alkaloid slows the action of the heart but increases the force of the beat, and markedly augments the blood pressure, contracting actively the blood vessels by stimulating both the vasomotor centres and the muscles in the walls of the arterioles. In the toxic dose it finally paralyzes respiration, although there is reason for believing that in the beginning it stimulates the function. Death occurs from asphyxia, to which is usually ascribed the final fall of the arterial pressure. Although there has been some conflict of evidence, it seems finally established that hydrastinine is a powerful oxytocic. According to experiments of Archangelsky, its administration to pregnant animals is very commonly followed by abortion. According to Faber, when given hypodermically during human parturition, it very notably increases the force and length of the uterine contraction, and is capable, in sufficient dose, of causing a tonic spasm of the uterus similar to that produced by ergot. Its action upon the uterus appears to be independent of any other of its influences, and to be direct. It would seem that it is a universal muscle poison,

¹ E. Schmidt, in studying this production of hydrastinine by oxidation from hydrastine, was led to make some interesting comparisons between hydrastine and narcotine. The latter of these he considers to contain three methyl groups, thus, $C_{10}H_{14}(OMe)_3NO_4$, while the former contains only two, thus, $C_{10}H_{15}(OMe)_2NO_4$. Since the oxidation of narcotine with manganese dioxide and sulphuric acid yields opianic acid and cotarnine, and under the same conditions hydrastine gives opianic acid and hydrastinine, and, further, as opianic acid contains two methyl groups and cotarnine one of these groups, as shown by Wright, it follows that hydrastinine contains no methyl group, and cotarnine may prove to be a methylated hydrastinine. The author hoped later to succeed in converting hydrastine into narcotine. (A. J. P., 1888, p. 635.)

primarily stimulant in its action, and that in this way it affects the heart, the arterioles, and the uterus. According to von Bunge, it markedly increases peristalsis, so that even the intestines do not escape its muscular action.

Hydrastinine was originally recommended by Falck in the treatment of *menorrhagia*, *metrorrhagia*, *dysmenorrhœa*, and even *endometritis*. The testimony as to its value in all forms of uterine hemorrhage seems to be conclusive, and it is affirmed by many gynecologists that it has a pronounced alterative influence upon the mucous membrane of the uterus. From our own experience we are convinced that it has value as a cardiac tonic, not equal in power or certainty of action to digitalis, but often useful as a substitute for that drug, especially in minor cases of heart failure. Its sedative action on the centric nervous system, conjoined with its stimulating influence upon the circulation and its pronounced effects upon the genital system, make it a very valuable remedy in the treatment of feeble women of hysterical temperament, with tendency to uterine fluxes.

Dose, usually employed, from three-fourths of a grain to one and a half grains (0.048 to 0.096 Gm.) every three to six hours, but probably larger doses might often be used with advantage, since no ill effects have been as yet recorded as being produced by it. The salt may be given hypodermically.
